ICE AGES

M

: Solving the Mystery

Professor John Imbrie and Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Nuclear powers must act quickly

FOR the next few months the question of ratification of the SALT 2 treaty by the US Senate is bound to occupy the attention of most Western arms controllers and politicians with an interest in arms control. Then early next year, regardless of the outcome of the SALT debate, their thoughts will have to be diverted to the five-yearly review conference of the Non-Proliferation Treaty (NPT) planned to take place in May 1980. And it is certain that the NPT conference will be the occasion for yet more bitter questioning by the non-nuclear-weapon states of the seriousness of commitment of their nuclear counterparts to Article VI of the NPT, which said that all parties to the treaty undertook to "pursue negotiations in good faith on effective measures relating to cessation of the nuclear arms race at an early date and to nuclear disarmament . . . ".

A successful outcome to the SALT debate would certainly tone down the criticism to a certain extent. But it is clear that what the non-nuclear-weapon states really want is a weapons-test ban. Diplomatic wording of the agreed statement at the end of the 1975 NPT review conference could not conceal exasperation at continued testing. "A considerable number of delegations" wanted a ban for a specified time, with a view to negotiating eventually a "universal and permanent cessation of all nuclear weapons tests". Such a treaty has yet to come about.

True there is now US-Soviet agreement to restrict tests to a maximum of 150 kilotons yield. (The UK uses the US test-site for its one or two explosions per year so is also bound by this agreement; the French and Chinese are not.) True there are US-UK-Soviet talks proceeding at present on a possible short-term treaty. True there has been some softening of the previous Soviet intransigent position on monitoring stations on its own soil. But there is as yet little evidence that there will be a solid treaty by the time of the NPT conference. Two points are as yet unresolved.

The first is rather silly. Some months back the Soviet Union proposed that for the three-year period, now regarded as the most that a ban would be negotiated for, each party to the tripartite talks would have ten seismic monitoring stations on its soil to verify compliance — the data to be mutually available. This was a big step forward for the Soviet Union, but did they really mean ten stations on British territory? Apparently they did. British territory does not amount to much these days outside the UK. There would be no scientific point in more than two stations in the UK to monitor compliance, and for the rest the instruments would have to be placed in Hong Kong (useful for keeping an eye on the Chinese, were the noise levels not so high) and sundry remote islands, probably equally noisy and therefore useless. As the monitoring posts are supposed to be the best that technology allows, the bill for this futile operation could not be less than tens of millions of pounds. The British, who on the whole wanted to take a back seat in these negotiations and not get in the way of a superpower agreement, suddenly find themselves pushed up front in rather a ridiculous way. Scientific honesty requires that they resist this pointless waste of resources; political necessity requires that they not let the Soviet Union make capital out of it.

The second sticking point is more substantial. After a three-year total ban, what comes next? On the surface the question is what to call the review conference at the end of the period, but the real issue is whether a three-year ban could ever be converted into a longer one. Yes, say the Russians, if the Chinese and French behave themselves and if some way can be found of coping with 'peaceful' explosions (a thorny problem). No, say the Americans, we can't be tied; there is enough domestic opposition as it is to any ban at all — the weapons laboratories are pushing the issue of stock-pile testing harder year by year and claiming (not without dissenting voices) that weapons untested for long periods will be unreliable. Aldermaston, with its trans-Atlantic ties, would say the same if allowed to be asked, but the British are burying any internal differences in a united front of keeping the options open for longer term ban. Mrs Thatcher is known, however, to be showing some interest in the UK test ban position; it is on the cards that Britain might eventually show less enthusiasm for long term restraint. Whatever agreement is finally reached, it is indisputable that in the US, the President will have to sell it very hard by means of vigorous 'safeguards' such as more, not less, financial support for the weapons laboratories.

Time, it hardly needs saying, is running out for a convincing treaty to be prepared before the NPT conference, especially as the multilateral Geneva Disarmament Conference will want to take a look at it. Non-nuclear-weapon states are, rightly, going to work up a head of steam over the failures to prevent vertical proliferation whilst they have been restrained from horizontal proliferation. Their position of restraint is not made easier by the continual gossip about the nuclear capabilities of South Africa, Pakistan and Israel. Unless the three negotiating nations put a lot more goodwill into their discussions in the next few months they will deserve all the obloquy they will certainly get. □

British scientists wait for crucial decision that could ease pressure on promotions

In two weeks the Science Research Council is to make a decision on a controversial plan aimed at easing the critical staff stagnation problem which now affects universities in the UK. On 18 July, its central council will decide whether or not to give the go-ahead to a special release fellowship scheme that is intended to help more senior research workers vacate tenured posts which can then be filled by young scientists.

The age structure at UK universities has been deteriorating since the higher education expansion of the early 1960s, when new departments were created and were manned at senior levels with young scientists. In recent years, economic recession has ended the creation of additional posts and the distribution of posts has been frozen.

Indeed, in some science departments there have been no new appointments for the past ten years. Where there have been vacancies these have been filled from within departments, thus halting the crucial flow of ideas and talent between universities.

Now, in an attempt to stop this stifling of fresh talent, the SRC is seriously considering the establishment of special fellowships which would fund research workers advanced in their careers and allow them to leave university posts to concentrate solely on research without administrative responsibilities. Their vacated positions would then be filled by young scientists and over subsequent years allow the phasing-in of new research workers.

However it is stressed that the scheme is not meant as a form of premature retirement for ageing researchers, and only those who are active and still have important scientific contributions to make will be considered for funding.

The proposal to be discussed by the SRC this month is for 15 fellowships to be set up in the first year of the programme with further annual increments of 10 new awards. This could then provide a total of 45 special release fellowships within four years.

But there are several difficulties associated with this plan. For one thing, it has not yet been agreed whether the SRC should pay for the senior researcher's salary or if it should pay for the junior post. The difference could represent a variation of about 50% in final costs and consequently estimates vary between £300,000 and £450,000 a year for the ultimate price of the full fellowship scheme.

However the council is at present particularly concerned about its future budget allocations and may be very reluctant to commit itself to such a level of funding. At its meeting, it may decide to cut the numbers of fellowships or may even postpone any decision until September when it hopes to learn its financial guidelines for the coming years.

Indeed, some council members are very cautious about the whole idea of the scheme, believing it be the role of the University Grants Committee to provide proper staff structures within departments. Combined with these other factors, this view puts the council's coming decision very much in the balance.

Robin McKie

Dearer oil puts brake on Third World growth

THE effect of the current energy crisis on Western nations has attracted considerable international attention but precious little has been said about the non-OPEC Third World countries. Energy experts who gathered at a forum on 'Third World Energy Strategies and the Role of Industrialised Nations' organised recently (20-22 June) by the Royal Institution in London, described an extremely critical energy situation developing shortly in these countries, which could almost threaten their very survival.

Their predicament was well illustrated by a case study of Kenya presented by T. S. Tuschak, a UN energy consultant based in Nairobi. Mr Tuschak pointed out that Kenya consumed in 1978 a little less than 12 million barrels of oil (equivalent to about one week's consumption in Canada). This small quantity of oil accounted for about 85% of the energy consumed by the country's modern sector. About 80-82% of this oil was consumed in essential sectors like industry, agriculture and goods transport. The rest was accounted for by private automobiles, which too in many cases were not inessential because of an underdeveloped public transport.

The possibility of oil savings in the essential sectors is at best 7%. Consumption by private transport can at best be reduced by about 10%. Kenya, therefore, has few options but to maintain oil imports at near current levels, and will possibly even have to increase them if the economy continues to grow.

Tuschak estimates that for $1/barrel increase in oil price, the country's export earnings would have to increase by about 1% over the 1978 level. This expansion in exports may sound small but could well be impossible considering the global slow down in economic growth.

Coffee and tea represent 50-60% of Kenya's total exports and they are about the only commodities in the country capable of any significant expansion in world markets. Their export would have to increase by as much as 30% in a year to cover the incremental foreign exchange needs. "The only way to meet this bill," said Tuschak, quite despondently, "is to further impoverish the country, by paying for oil by funds destined for development". Few developing countries will be able to afford an oil price of $20-22/barrel.

The other possibility, of course, is for Western countries to bale out the developing countries. But this option brought forth only a spirited discussion, virtually no agreement.

Stephen Bosworth, the US Ambassador to Tunisia, and former chairman of North-South negotiations on energy at Paris, plainly warned Third World energy planners that Western aid and loans from international financing institutions are unlikely to rise fast enough to meet the needs generated by oil price rises. Nor is an oil sharing system which gives preferences to developing countries is likely to come into operation he said. The world will have a slower rate of growth in the future. "We have seen that Western parliaments react unfavourably to any real transfer of resources in those conditions."

The discussions on alternate energy sources that could replace oil revealed two important Third World concerns; first, that the Third World is extremely unhappy with the constant preaching by Western scientists and technologists that unconventional energy sources like wind and solar power, and fuelwood plantations are best for it. All Third World energy experts gathered in London agreed that these energy sources would be good for developing countries but they would first want them to be fully tried and tested.

Secondly, they pointed out, none of these sources can provide an alternative to oil in the short-term which is really the critical period for the non-oil producing Third World.

Dr A. K. N. Reddy of the Indian Institute of Science at Bangalore threw an outright challenge to the developed countries: "Teach us to live without oil but by doing it yourselves". That the developed countries must first put their own house in order was a demand that was echoed by many Third World participants.

Dr Joao A. Meyer, of the State University of Campinas in Sao Paulo, criticised Western efforts for following their traditional approach to technology transfer even in the new field of non-traditional energies. They are once again trying to sell gadgets, instead of trying to

0028-0836/79/270002-02$01.00

Fledgling transport systems could be hit by petrol shortages

help developing countries solve their own problems, he said; the only difference now is that the accent is more and more on solar power plants instead of nuclear plants.

"Often we do not even know whether immature energy technologies are being pushed upon us", Dr Meyer alleged. "And where we have developed technologies indigeneously, for instance, the production of alcohol from sugarcane, we find ourselves besieged with claims of patent infringements and demands for royalties."

Among alternate energy sources, discussions centred on wood, which provides over three-quarters of the Third World's population with its energy needs. For these people, the wood crisis is worse than the oil crisis, and certain to become even more acute. Kenyan experts revealed that wood scarcity in their country is already so acute that serious thought is being given to providing electricity for cooking in rural areas to replace the use of firewood. "Until 1973, we thought we had the wood problem licked", said India's energy planner Sankar. "We were subsidising the use of kerosene in villages to replace the use of firewood. But then in 1973 the carpet was pulled out right under out feet."

The answer is to grow more wood; but the forum discovered that first, scientists themselves do not have adequate knowledge about fast growing trees and forestry techniques, and second, even if existing knowledge could be applied right away, a British expert pointed out, it would be 1996 before rural areas could get wood. Problems of social organisation in Third World villages will prevent rapid diffusion of innovations. India's progress with biogas plants to meet rural cooking energy needs has also been very slow.

There was, however, total unanimity on the need for developing countries to plan their future energy use carefully and to discover new sources. Once developing countries identify their energy problems, and choose the technologies they want to solve them, then the developed countries can help them in developing those technologies instead of passing on to them packages that imitate successful ones in the West, said Professor Ignacy Sachs of the University of Paris.

However, the forum learnt that though very soon most Third World countries would be setting up ministries of energy, few of them had either the relevant information systems or the trained personnel with analytical capabilities to make proper economic, social and technical choices in the energy sector. It is here that developed countries and international organisations can help most, felt the Third World participants.

Professor M. S. Wionczek of Mexico suggested the establishment of an institute for advanced studies in energy policy, possibly similar to the Institute of Theoretical Physics at Trieste, a unique institution which provides scientists from developing countries an opportunity to meet and discuss with leading scientists, including Nobel laureates from developed countries. Venezuela's Minister of State for International Economic Affairs, Mr M. Perez-Guerrero, suggested a new institute be set up within the UN to help Third World countries in energy planning.

But there were no solutions to the problem that Third World experts had themselves identified: what do developing countries do to solve their energy problems in the immediate future? As India's Sankar put it: "I find no dearth of experts prepared to chart out an energy strategy for the year 2000. My problem, however, is 1980 and 1981. Who will help me solve that?"

Anil Agarwal

Experts agree on Mediterranean pollution treaty

Scientists from 14 of the 18 Mediterranean states unexpectedly agreed last week on the text of a treaty to control land-based sources of pollution — but the rate of implementation of the treaty will depend on how fast scientific work can be completed.

"The deadlock is over" said the director of the United Nations Environment Programme's regional seas unit, Stjepan Keckes, this week, "but it is not the breakthough that some newspapers have reported".

One of the main obstacles had been a disagreement between the northern, industrial nations, and the southern underdeveloped states, over whether to impose uniform emission standards on polluters, or to define common goals for coastal water quality. The underdeveloped states argued that the former would penalise the growth of new industry in an area which presently had little industry and little pollution; while the north contended that the latter would allow the south to develop cheap and heavily polluting industries which would compete with more expensively controlled northern firms. In the end the underdeveloped states won the argument, and the treaty specifies coastal water quality standards. "This is the most logical arrangement" Keckes told *Nature*. "It is the same pragmatic scheme you operate in Britain".

The treaty will go to a specialist diplomatic meeting in Athens in April for signature. Ratification comes later.

"These are the first steps", said Keckes, a marine scientist who is also in charge of the scientific assessment of the state of the Mediterranean. "But we don't have enough evidence yet. We can define water quality for bathing, using a microbiological standard — we've been measuring on 150-200 beaches — and later we hope to define heavy metal limits for shellfish growing" he said. "But the rate of implementation of the treaty will depend on how fast we can define stanards scientifically."

Progress is therefore limited by the money UNEP can spend on its pollution monitoring programme, 'Medpol'. Earlier this year, a full meeting of the contracting states voted to delete Medpol's air pollution research programme (see 15 February p 506) — whereas air, Keckes feels, may be the main source of the central Mediterranean's metallic pollution.

"The research programme needs an additional boost and additional money" said Keckes. He hopes to present a strong case for restarting the air pollution programme to the next full meeting of contracting states in February 1981.

Proxmire must answer libel charge

THE US Supreme Court last week decided that Senator William Proxmire could not claim Congressional privilege in making derogatory remarks about a scientist's research in press releases and news broadcasts announcing his Golden Fleece award. The award is presented regularly to esoteric-sounding research projects supported by federal funds.

The court also decided that, in claiming libel damages for remarks made by the Senator in presenting such an award, a scientist should not be considered a "public figure" by virtue of having received public funds, and therefore was not required to demonstrate that the remarks had been made with deliberate malice.

The Supreme Court's decision was based on an appeal made by Dr Ronald R Hutchinson of Kalamazoo, Michigan, in connection with a libel suit that he had filed against the Senator following the award of a Golden Fleece to the National Aeronautics and Space Administration for supporting Dr Hutchinson's research on the latent aggression of laboratory monkeys.

Labelling the research as being to study "why monkeys clench their teeth", Mr Proxmire claimed in a speech to the US Senate in 1975 that "the good doctor has made a fortune from his monkeys and in the process made a monkey out of the American taxpayer", a charge he repeated in a newsletter to his constituents and a subsequent radio television interview.

Dr Hutchinson subsequently filed a libel suit, claiming that Mr Proxmire's actions had caused him to be held up to public scorn and resulted in a loss of respect in his profession, as well as "loss of income and ability to earn income in the future".

The suit was rejected by a lower court partly on the grounds that Dr Hutchinson had become a "public figure" by soliciting government grants and publishing articles in professional journals, which required him to demonstrate "actual malice", and partly because Senator Proxmire claimed legislative privilege in making the remarks.

In last week's decision, however, the Supreme Court stated that, although local newspapers had reported Dr Hutchinson's receipt of research grants, and although he was quoted in the press in reacting to the Golden Fleece award, neither of these was sufficient to make him a "public figure".

"His access [to the media] such as it was, came after the alleged libel and was limited to responding to announcement of the award. Those charged with alleged defamation cannot, by their own conduct, create their own defence by making the claimant a public figure," the court announced.

On the question of legislative privilege, the court ruled that this could not be used by the Senator as a defence, since there was no evidence of past Congressional concern to grant absolute privilege for remarks made outside the legislative chambers, since neither the news-letters nor the press release were "essential to the deliberation of the Senate", and neither was protected as part of the responsibility of members of Congress to inform the public of their activities.

In the light of these decisions, the Supreme Court directed that the case be returned to the Court of Appeals "for further proceedings consistent with this opinion". In a dissenting opinion, Mr Justice Brennan declared that in his opinion "public criticism by legislators of unnecessary governmental spending whatever its form, is a legislative act shielded by the Speech or Debate clause". □

NASA bets 50-50 on space shuttle next summer

OFFICIALS of the US National Aeronautics and Space Administration told a Congressional committee last week that the first orbital flight of the reusable space shuttle is not now likely to take place until next summer at the earliest, and that this may mean at least four satellites scheduled for early shuttle launches will have to seek alternative ways of getting into orbit.

Dr Robert Frosch, the agency's administrator, told the House Science and Technology Committee that technical delays in the development of the shuttle's engines and in fitting its heat-resistant surface tiles meant that there was now only a one-in-five chance of launching the shuttle by the end of the first quarter of 1980, a launch originally planned to have taken place this spring, and a 50-50 chance of a first flight in the second quarter.

"This slip means our first operational flight, which had been planned for February 1981, will be delayed until September 1981," Dr Frosch said. "This means some of our early users will have to shift to use the backup expendable launch vehicles to get their satellites into orbit." (It also means that it will now be necessary to revise the launch schedule for the European Space Agency's Spacelab, which was due to be launched by Space Shuttle in August 1981).

Among the satellites whose launches will be affected by the new shuttle delays is a geosynchronous operational environment satellite which was planned to be launched by the National Oceanographic and Atmospheric Administration; shifting from a shuttle launch to an expendable launcher could increase the cost from about $10 million to $22 million, and the same would apply to two commercial communications satellites that were to have been among the first payloads. □

New warning on risk from antibiotics in animal feeds

THE US Congress' Office of Technology Assessment reported last week that antibiotic resistance is continuing to increase in the US population, and warned that, although quantative relationship remains uncertain, the continued use of antibiotics in animal feeds seems to be contributing to this process.

The OTA's warning came in a report on "Drugs in Livestock Feed" prepared at the request of the Congress following the Food and Drug Administration's proposal in 1977 to ban the use of penicillin and sharply restrict the use of two tetracycline drugs in animal feed. According to the industry, sales of antibiotics and similar antibacterial agents added to animal feed exceeded $180 million last year; and the OTA estimates that the FDA's proposed restrictions could increase retail meat and poultry prices by between 3% and 28% in one year.

However the OTA also says that antibiotics in animal feed contribute to a "growing pool of drug-resistant bacteria", and that physicians are now reporting reduced effectiveness of the drugs in treating disease; and it points out that many of the drugs on which restrictions are proposed could be replaced with alternative drugs that are already approved by the FDA.

It is up to Congress, the agency concludes, to weigh the economic costs of banning the drugs in animal feeds against the health risks of allowing their continued use. "These decisions involve value judgements that cannot be based simply on monetary considerations. And the lack of scientific certainty on the magnitude of both the probable health risks and the attributed increases in meat production makes the formulation of a balance-sheet approach difficult," the OTA report says.

The short-term consequences of a ban on the drugs could be significant, since production might decrease, leading to higher prices. But the OTA says that the long-term consequences are less certain, probably resulting in small decreases or no changes in production and small increase in both consumer prices and overall producer incomes.

Dr Joyce Lashoff, OTA's assistant director for health, emphasised at a press conference last week that the OTA made no specific recommendations about how Congress should act, merely listing a range of options. Giving a personal view, however, she said that she believed the availability of substitutes meant that the economic impact of the regulations proposed by the FDA would not be great enough to offset the potential risk to human health if the use of antibiotics remained unrestricted. □

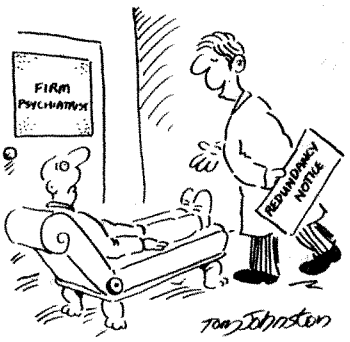
news in brief

New agency proposed to handle nuclear waste: A loss of confidence in the US Department of Energy's ability to come up with a co-ordinated nuclear waste disposal programme means that the problem should be handed over to a new committee of federal and state representatives, the General Accounting Office, the investigatory arm of the US Congress, announced last week. In a report prepared at the request of Senator John Glenn, the GAO pointed out that a number of states had already passed various forms of legislation concerning how nuclear waste issues should be handled, but that the federal government had so far failed to come up with an acceptable permanent storage plan for high level wastes. This was becoming a growing obstacle to the development of nuclear power. "We believe it is very unlikely that making the Department of Energy the responsible lead agency to plan and co-ordinate the programme will establish public trust and confidence", the GAO report states.

German mathematician fights 'Berufsverbote': The case of Horst Eckart Gross, 36, who was excluded from a job as assistant professor at the University of Oldenburg, has entered a new phase. West German authorities are now arguing that the recent public campaign in support of Gross' employment is further evidence of his "unconstitutional behaviour". Gross was nominated for a position teaching the history and professional practice of mathematics by the normal university committees in February 1977. The Verfassungsschutz, the West German body responsible for vetting political opinions of government employees, delayed the appointment for almost a year and then said in its final report that there was information which gave reason to doubt Gross' loyalty to the "Freiheitliche Demokratische Grundordnung" (free and democratic constitution). The information in question consisted of Gross' activities in a German-Cuban friendship society which has local groups in more than 30 West German cities. Members of the organisation include trade unionists and members of parliament. Gross is also accused of membership of the German Communist Party and of past membership (1967/68) in the SDS.



The council of the University of Oldenburg passed a strong resolution in support of Gross on 11 January 1978 protesting at his examination by the Verfassungsschutz and calling for his immediate employment. "This Berufsverbote case shows perhaps more clearly than any other the unconstitutional methods used by the political police", it said.

Cuba to build nuclear reactor: Cuba is proceeding with a plan to build the first nuclear power plant in the Caribbean. Mr Luis Beltran, minister in charge of the electrical power industry, announced last week that construction on the Soviet-designed reactor would start this year at Cienfuegos on Cuba's southern coast. The reactor is of the pressurised water type similar to the one involved in the Harrisburg accident. Mr Jorge Perez-Lopez, a US government economist, claims that the Soviet design lacks two safety features which are common to PWRs built in Western Europe and the US. Writing in the magazine Cuban Studies, Perez-Lopez says that Soviet PWRs lack a backup cooling system and an outer casing to contain possible leaks. Perez-Lopez suggests that Cuba and the Soviet Union have a mutual interest in developing Cuban nuclear power at this time. The Soviet Union conserves its oil supplies for trade on the world market and Cuba lessens its financial dependence on Soviet oil.

'Plenty of jobs in the UK': According to Neil Macfarlane, minister of science in the new Conservative government, jobs are going begging in the UK. Speaking at an Association of British Science Writers lunch, Macfarlane stated that "for people with the right skills there are plenty of jobs". When asked whether this included scientists on short-term contracts, Macfarlane declined to comment, agreeing with his host, Roger Lewin, deputy editor of *New Scientist*, that "the issue was too complicated for a brief discussion".

Meanwhile, the Department of Education and Science has just released a recruiting pamphlet, Science at Work, intended to attract school students to science careers. The pamphlet is one of a DES series whose "main emphasis is on educational courses and qualifications that lead to jobs". It will be circulated to all schools, colleges and careers offices in the UK. The booklet specifically cites teaching as a career option. "To ensure the continuity of science progress, there is always a need for scientists as teachers in schools, colleges, polytechnics and universities." Also listed are possible careers in microelectronics and librarianship. *Science at Work*. Department of Education and Science, Room 2/11 Elizabeth House, York Rd, London SE 7PH. Free.

Europeans are afraid of new science and technology: A public opinion poll shows that 80% of the people in the EEC fear for the future of the world they live in because of the "despoiling of natural life and the countryside through pollution of all kinds". A second major fear (67%) is of widespread unemployment caused by automation. A majority (53%) also expressed concern about new technologies in housing, traffic and food and the introduction of drugs that "may severely affect the human personality". The study had been requested by the EEC Commission from European Omnibus Survey, a group of eight specialised institutes in the member countries. Four countries — Germany, Denmark, the Netherlands and the UK — rank pollution as their number one concern and four others — France, Belgium, Ireland and Luxembourg — rank unemployment first. The Italian public fears an overall deterioration of living conditions. This includes the conviction that science is not being used for the benefit of the population as a whole.

"And just how long have you had this fear of unemployment caused by automation?"

The poll shows that even though only 10% considered themselves sufficiently educated to discuss science competently, the majority insisted on being involved in major development choices. The nuclear power questions show that the public has been convinced that curtailing nuclear power could mean loss of electricity. But at the same time, 36% are still opposed to nuclear power compared to 44% who favour it. The poll disagrees sharply with a 1977 survey, which showed "clearly" that there was no mistrust of science. *The European Public's Attitudes to Scientific and Technical Development*. Commission of the European Communities. Brussels.

ETSU finds most renewable energy sources safe: The UK's Energy Technology Support Unit has given an environmental clean bill of health to most renewable energy sources. In a preliminary report to the Department of Energy, the unit finds that the impact of solar and wind energy conversion is "likely to be relatively small". The impact of tidal energy and wave energy is considered to be more complex. Wave energy converters could interfere with herring and salmon migration paths and with ship navigation.

The report lists 13 areas of concern about tidal energy conversion, including effects on ports, freshwater fisheries, pollution dispersion and agriculture; £1.5m has been devoted to the further study of these effects. *Environmental impact of the renewable energy sources*. ETSU, Harwell, OX11 0RA.

Alpha-fetoprotein screening: too hot to handle?

US manufacturers want to market pre-natal screening kits for anencephaly and spina bifida. But can US medicine cope with the risks? **David Dickson** reports

WHEN Dr Donald Kennedy returned to Stanford University last Friday after a two year spell as Commissioner of the Food and Drug Administration, he left unresolved a classic but little-publicised example of the problems society faces with potentially hazardous technologies: namely whether — and if so under what circumstances — the FDA should approve the marketing of techniques capable of warning an expectant mother that she is bearing a child with a serious birth defect.

The techniques in question use a radioimmunoassay to measure the level of alpha-fetoprotein (AFP) in the mother's blood serum. A high level of AFP indicates that the foetus has an above-average — although still relatively small — chance of suffering from a neural tube defect (NTD), manifest at birth as either anencephaly or spina bifida. A precise diagnosis can subsequently be achieved using ultrasonography and amniocentesis.

If properly used, this series of tests could theoretically pinpoint the one or two children in a thousand born in the US with a neural tube defect at a sufficiently early stage of pregnancy to permit an abortion, if the mother so chooses. A wrong diagnosis, however, or a misintepretation of preliminary test results, could lead to the abortion of a healthy foetus.

It is a situation in which even obstetricians have expressed doubts about their present ability adequately to handle the whole testing procedure. The FDA, to which a number of manufacturers have submitted applications for licences to market AFP screening kits, now faces the problem of building sufficient checks into the licensing process to minimise the risks involved. In doing so, some fundamental questions have been raised about the ability of an essentially free-market medical system to provide the coordination, support and oversight needed to make this possible.

The discovery that neural tube defects are associated with high levels of AFP in the amniotic fluid was first made in the early 1970s by two scientists at the University of Edinburgh in Scotland. It is thought to occur because the defect allows the protein, which is only found in foetal blood, to leak into the surrounding amniotic fluid.

Early tests showed that measuring AFP level by amniocentesis provided a highly accurate guide to the chances of a foetus suffering an NTD. And subsequent tests in the United Kingdom also indicated that merely measuring AFP levels in the mother's blood could provide an initial clue to such a likelihood.

The problem, however, is that a correct diagnosis based initially on serum testing requires a number of separate further steps, each of which has to be carried out with a high degree of accuracy. Firstly the AFP level in the maternal serum must be measured between the 16th and the 18th week of pregnancy; if the AFP reading is abnormally high (typically considered to be in the top 5% of mothers tested), a second measurement is made, although the woman still has only a one-in-fifty chance of carrying a defective foetus.

A second high reading, indicating a 10% chance of a defect, leads to further testing to discover the reason. Ultrasonic examination of the womb can usually indicate if the foetus is anencephalous, or if the high AFP is caused by twins or premature death. If none of these is found, anmiocentesis — which is not in general applied earlier, since the risk of accidentally inducing an abortion is higher than the general one-in-a-thousand risk of bearing a defective child — is used as a final check.

A $25 million business

In theory this complete screening procedure, if made generally available, could lead to a significant decrease both in the 2000 to 3000 children who are born and survive every year in the US with spina bifida, and in the anguish to the parents of those (in particular the anencephalics) who do not survive at birth. A national programme has therefore been urged by many, and is already being studied in Britain, to minimise what is currently the most common serious birth defect. Manufacturers envision a multi-million dollar market for their screening kits and reagents; and private laboratories a comparable market for their testing services.

Three main concerns, however, have been raised by the prospect of the techniques being freely marketed and becoming generally available. The first is the general opposition of the politically powerful anti-abortion lobby, critical of what one Right to Life committee member last week described as any "search and destroy" mission involving pre-natal screening.

The second concern is on the economics of mass screening, and revolves around cost-benefit arguments. Research workers at the Center for Disease Control at Atlanta, Georgia, have calculated that a screening programme offered to all pregnant mothers in the US, with a 40% acceptance, would cost about $25 million a year; but the averted annual cost would be about $50 million. Others challenge these figures, arguing that the risks are insufficiently known to enable realistic quantification.

It is the third consideration, however, which is presently causing the greatest headache to FDA officials, namely how to ensure adequate quality control of the whole process, and not just of the screening kits, to minimise the risks involved. For as one FDA official points out: "The use of the test is so integral to obstetric practice that it is hard to look at this purely as a technique without also taking into account the way that it is going to be used."

Such concerns, focused in particular on the dangers of causing large numbers of unnecessary abortions, have four main aspects:

- how to ensure adequate counselling for the parent, both with respect to gaining initial "informed consent" and to correctly interpreting the test results at various stages;
- how to ensure physicians are sufficiently informed about the techniques to be able to interpret laboratory results properly, and provide follow-up guidance;
- how to ensure that the complete range of testing facilities is available to every mother taking the test, so that a decision to abort, for example, is not made solely on a positive first test due to the lack of sonography or amniocentesis facilities (or an inability to pay for both); and
- how to ensure sufficient accuracy in the information provided to physicians by testing laboratories.

Although such issues have been debated in academic circles for a number of years, alarm bells only started ringing at the FDA last Autumn after a hearing of a review panel of the agency's Bureau of Medical Devices on applications to market screening kits which have been developed by a number of manufacturers, including Hoffman la Roche, Abbott Laboratories, and the Wampole Division of Carter-Wallace Inc.

Shortly after the hearing, Mrs Carol Bucholz, a director of the Spina Bifida Association, wrote a strongly-worded letter to Dr Kennedy complaining that, as "the obvious consumer population" the association had been neither informed of nor represented at the meeting.

Members of the association mounted a vigorous letter-writing campaign to the FDA. And in their opposition to unrestricted licensing, they were soon joined by other groups and institutions. The director of the Center for Disease Control, for example, Dr William H Foege, wrote that without proper control, AFP screening could lead to unnecessary abortions and false-negative diagnoses which would "continue to be made until successful malpractice suits alter medical practice to stop these mistakes".

The Health Services Administration an-

0028-0836/79/270006-02$01.00

© Macmillan Journals Ltd 1979

nounced that it did not feel adequate facilities existed to provide the necessary sonography and anmiocentesis services if the screening technique became suddenly available on a national basis. "We therefore recommend deferral of the approval for the production and marketing of the test kit at this time", the head of the HSA wrote to Dr Kennedy.

Perhaps most significantly, opposition to unrestricted licensing was also expressed by two professional medical bodies, the American College of Obstetricians and Gynaecologists, and the American Society for Human Genetics. ACOG admitted openly that, in addition to sharing the concerns of others, it did not feel its members were sufficiently prepared to carry the responsibility which the general availability of AFP screening techniques might impose.

"Our position is that we need to have a realistic protocol and set of guide-lines prepared both for the physician and for the patient. It is going to take institutional approaches and a lot of education to learn how to use this technique properly, and we are concerned that it should not be turned loose until we have worked out our line of approach," Dr Ervin E Nichols, director of practice activities at ACOG, told *Nature* last week.

Many of these views were aired at a further public hearing of the medical devices panel in February of this year. However the director of the Bureau of Medical Devices, Dr David Link, subsequently recommended to the Commissioner that licences be granted without broad restrictions on marketing, and subject only to requirements for labelling, reporting, and the provision of information to physicians and patients.

But things were already stirring at the top of FDA. In March the agency announced that it was rejecting an application from Abbott Laboratories to have its screening kit reclassified from a category of medical devices that require pre-market testing on an individual basis, to one which merely required compliance with pre-determined standards.

In announcing its decision, and overriding the recommendation of an advisory panel that the reclassification be granted, the FDA stated that it was "not convinced that a standard would provide reasonable assurance of the safety and efficacy of the device" if it were reclassified as requested. It added that "the petitioner did not state how FDA could assume that ultrasonography or equivalent procedures, i.e. amniography, would be used for determining gestational age", essential information for correct interpretation of the test data.

The various groups have now met with top officials at the FDA to state their case. And it appears that, despite the continued opposition of some manufacturers, the FDA is now prepared to add restrictions to the licences that it issues. A possible protocol is now being developed by ACOG and the American Academy of Pediatrics. And the big question is how far restrictions will go; for, given that all parties in the debate accept the need for a high degree of quality control, the issue remains of how in practice this should be ensured, in other words how sufficient public accountability can be achieved.

On several points both the manufacturers seeking licences and those seeking restrictions on such licences are broadly in agreement. For example ACOG is now working on appropriate forms of physician and technician education, with considerable support of the manufacturers (some of whom have already produced trial educational material to this end).

Who is in control?

The main source of controversy, however, is over who should control the quality control process. Manufacturers and laboratories see quality control as essentially a technical issue; they would like the federal government to agree on standards of accuracy, and then merely be required to meet these standards. Critics, however, such as the Washington-based Health Research Group, argue that this is insufficient; they want more direct public involvement and accountability, perhaps through either federal or stage agencies, in monitoring the way that laboratories conduct the tests, requiring for example, regular inspections rather than occasional proficiency testing.

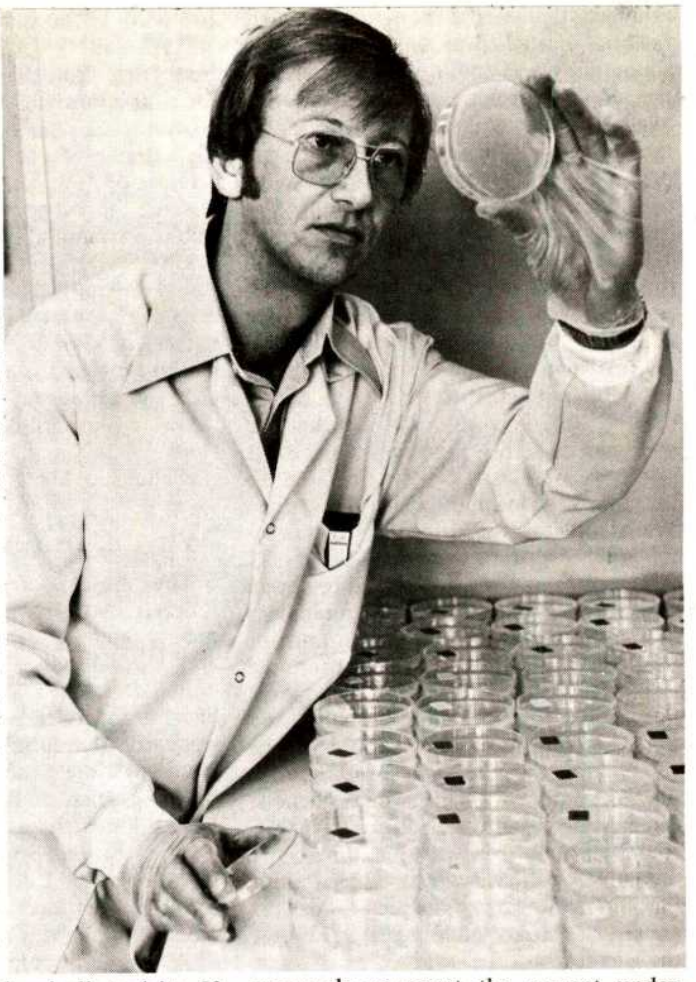
Direct regulation of laboratory practices, however, is taking the FDA into unchartered areas. At present, government regulation is a "loose, patch-work affair" according to Mr Robert Leflar of HRG, with responsibility for different types of laboratories divided between different agencies. The FDA is confident that it can devise an adquate control system, possibly through the CDC; but has yet to announce details of how this will be done.

One approach which, some feel, would act as a half-way house to general marketing of the screening techniques would be through carefully-controlled pilot programmes. One successful pilot programme has already been in operation for several years on Long Island, run by Dr James Macri of the State University of New York at Stonybrook; another is being planned under the auspices of the State of Maryland's Commission on Hereditary Disease, set up in 1973 to guide methods for the detection and management in hereditary disorder in Maryland.

Listing the problems that surround the accurate use of AFP screening techniques, Dr Neil A Holtzman of the Johns Hopkins Medical School in Baltimore told the February FDA hearing that the commission "does not believe that these problems can be solved judiciously or expeditiously if tests are offered by private laboratories". The pilot project soon to be launched with the cooperation of obstetricians and parent groups in the Baltimore area will be organised through the Laboratories Administration of the state's Department of Health and Mental Hygiene.

One advantage of a state-run project is that it can provide the close coordination between different individuals and institutions that is essential for the success of the screening test, but might otherwise be lacking in a more laissez-faire arrangement. "The solution (to unnecessary risks) will require the multiple agencies of the Public Health Service to cooperate, and PHS to cooperate with the private sector". Dr Foege of CDC wrote to the FDA, urging that a plan for such a policy "must be worked out before a kit or kits are marketed."

In Britain, such requirements have the advantage of being able to work through the National Health Service, and screening is now offered by a number of regional health authorities. In the US, where any moves towards "socialised medicine" are still strongly resisted, such tight coordination is a relatively new departure. "The need for quality control means that the various agencies will have to be part of a cooperative system of testing much broader than we are used to. The problems are difficult, but not, we think, impossible," one FDA official said last week.



FDA is expected to announce within the next few weeks the path that it proposes to take through this complex of issues. Its decision will be closely scrutinised; Mrs Bucholz of the Spina Bifida Association, for example, has warned that if restrictions on licences "are not carefully designed and planned for with due consideration we will not only withdraw our support of alpha-fetoprotein screening but will actively work to inhibit AFP testing".

On the other side, laboratories and manufacturers could well seek recourse to legal constraints if they feel FDA is imposing unwarranted restrictions on their trade. But in the current absence of restrictions, some small laboratories are already offering AFP screening on a "bootleg" basis, with minimal control over either the quality of their test results or the way they are interpreted and used.

Thus what was until recently a largely ethical debate on the social implications of genetic screening has become an overtly political issue. In the case of nuclear power — perhaps not strictly comparable, but one where the same type of issues about controlling risk have arisen — it took the Three Mile Island accident to awaken broad public debate on the dangers of leaving the "control of quality control" too firmly in the hands of private enterprise, with insufficient public accountability. "We hope that the FDA will not make the same mistake" one observer said last week. □

Handle us with care

Alastair Hay reports on the reaction of chemical companies in the UK and US to safety legilsation and control of toxic substances

THE chemical industry is reacting in no uncertain manner to toxic substance control measures, introduced by both the US and UK governments as a result of recent public pressure and originating in concern over industrial pollution.

In the US in particular, the industry is objecting to proposals for testing the toxicity of new substances. Singled out for attack is the 1976 US Toxic Substances Control Act, which authorises the Environmental Protection Agency (EPA) to obtain production and test data from industry on selected chemical substances and mixtures, and to regulate the substances when needed.

The chemists are acutely aware of the political pressure to curb pollution, and their reaction to these proposals is not an outright condemnation of the philosophy of control, but a more subtle questioning of the validity of some of the measures designed to achieve it. Two issues are central to the chemical industry's concern: the variation found in the government control measures of different countries; and the scientific validity of testing procedures for toxic substances.

Britain's Health and Safety Executive (HSE) is sensitive to the protests from industry, but as the public guardian of the nation's safety, it is determined to achieve safer working conditions. The HSE policies the 1974 UK Health and Safety at Work Act, which requires industry — as the employer — to ensure that workplaces are safe. However, the means whereby this safety is assessed is still a matter of debate.

Last year the HSE issued a discussion document on a Notification Scheme for Toxic Substances, which would provide an agreed procedure for toxicity studies. There was no shortage of response, and this reaction has been taken into account by the Executive in the preparation of the next stage of the scheme: a consultative document. Views on this will again be sought before the notification scheme eventually becomes law.

The approach of the HSE to the regulation of toxic substances is in marked contrast to that of the EPA. Although the EPA guidelines for toxicity testing have yet to be finalised, one early draft suggested a specific battery of tests for assessing the toxicity of compounds. The HSE proposals on the other hand, are more flexible and selective. Mr Ted Langley, who has overall responsibility for the HSE notification scheme, outlined the philosophy behind the required toxicity testing as "the need to have a minimum set of data to enable movement to be made to the next stage (of development of a chemical) rather than a rigid set of tests, which may be very expensive." According to Langley the essence of the HSE approach is flexibility to "identify the hazard."

The HSE and EPA also differ in their approach to toxicity testing. The Executive's policy is based on an instalment plan, where sub-acute toxicity data generated over a 28 day study period will provide sufficient information to enable evaluations to be made about a chemical's toxicity. If the data generated in this period suggest the need for further research of a long term nature the HSE will then insist that this be done. The EPA, on the other hand, envisages a one-off, all-embracing package, which requires that a battery of tests, both short and long term, be undertaken before a chemical will be considered for registration.

The Chemical Industries Association (CIA) is the collective voice of the British chemical industry with a membership ranging from the huge multinational companies like ICI to very small concerns. On the question of safety the Association is on record as "fully supporting" a notification scheme for new chemical substances, but not unnaturally, it has some reservations about the new HSE proposals and even graver ones about the EPA Toxic Substances Control Act.

Mr Roy Granger is Director of Company Operations for the CIA and, as such, responsible for communicating the Association's views on the new regulations to the HSE and EPA. Granger does not mince his words when commenting on their proposals. On the Toxic Substances Control Act he says the "EPA shopping list of tests is unjustified" and that the CIA does not "want a rigid programme of tests." Granger approves of the HSE proposals which he says are based on a dialogue between the Executive and industry. In Granger's view the HSE proposals represent the current understanding of experts in the UK of the value of tests to assess toxicity.

In reply to the HSE and EPA proposals the CIA says it is concerned that UK proposals may differ from those being considered by the European Economic Community. It is also worried that the cost of doing the testing — and particularly the EPA tests — may prove so prohibitive for small or medium size chemical companies that it will be a barrier to innovation and to the introduction of new products on the market.

Furthermore, the CIA says that there is an acute shortage of toxicologists available to evaluate the tests; that intermediates in the chemical process should be exempt from legislation; that more thought must be given to the confidentiality of company data; and that the UK proposals which require notification for chemicals marketed in quantities above 1 tonne per annum are too stringent, and the figure should be raised to 10 tonnes. Raising this figure, says the CIA, would exempt many products and certainly most development chemicals from legislation.

For its part the HSE has let it be known that it is anxious to ensure uniformity in European legislation so that British manufacturers will not be unfairly penalised, and that HSE proposals may ultimately have to be modified to achieve these ends. The number of toxicologists available to evaluate data is not regarded as a long term

0028-0836/79/270008-02$01.00

© Macmillan Journals Ltd 1979

problem by the HSE, which points out that if necessary, it can look to Department of Health and Social Security toxicologists for advice. The HSE is building up its expertise in the field by an intensive "in house" training programme. The Executive will comment on intermediate products, confidentiality and tonnage in its consultative document.

The CIA claims in its submissions to the HSE and EPA that the views it expresses are those of its members. One such is Yorkshire Chemicals, a medium sized company based in Leeds, and dealing mainly in dyestuffs. It employs some 900 people and has an annual turnover of £22 million. Mr John Dawson, research director for Yorkshire Chemicals, agrees with most, although not all, of the CIA's views, saying for a start that the cost of toxicity testing is high. He feels that some of the new tests required by the HSE and EPA are "not justified" for dyes because, in his opinion, the tests required should be related to a product's final use.

To the best of his knowledge dyes themselves have never killed anybody, although he concedes that in the past his industry has used products such as ß-napthylamine and benzidine — which are carcinogenic in man — as intermediates. But he insists that toxic products such as these are no longer used.

Dawson's view is not shared by David Douglas, newly appointed head of the HSE unit responsible for collating information on toxic substances. Douglas insists that Dawson is "out of the mainstream of thinking on this one," as there is a risk to people from the breakdown products of finished dyes.

Many medium size chemical companies use outside research institutes, such as the Huntingdon Research Centre, to carry out toxicity testing. The dye stuff industry also shares much of its research data by operating collectively though the Ecological and Toxicological Association of Dyestuff Manufacturers (ETAD).

According to Dawson, the limited range of tests recommended by ETAD to assess the safety of their products are sufficient to assess the toxicity of dyes. In Dawson's view, "better hygiene could obviate the need" for some tests such as chronic oral dosing studies, and he doubts whether the CIA recommendation on raising the minimum tonnage of chemicals requiring testing would have a great effect on Yorkshire Chemicals.

Although many chemical companies complain about the cost of the HSE's proposed notification scheme, Ted Langley points out that the outcry is perhaps unnecessary. If, he says, industry is carrying out its obligations under the 1974 HSW Act to protect its workforce, then it should already be doing much of the testing which will be a feature of the new notification scheme. The difference, however, is that there will now be an agreed set of tests to do, and the results will have to be submitted to the Executive for evaluation. □

How ICI tests for toxicity

Few chemical companies can be as well prepared to undertake toxicity testing as ICI. The company finances its own laboratory, the Central Toxicology Laboratory (CTL), at Alderley Edge in Cheshire. CTL has a budget of £6 million for 1979. With a staff of nearly 300 the laboratory works in close collaboration with ICI's Occupational Medical Service (OMS) and both CTL and OMS have had substanial influence on the philosophy behind the HSE approach to chemical toxicity testing in the UK.

The science of toxicology is still in its infancy, according to scientists at CTL. They believe that research into new methods for assessing toxicity is essential to generate new tests which may be more rapid but, most important, are valid and reliable. Dr Iain Purchase is an Assistant Director at CTL and he believes that both the search for new test systems and work on understanding toxic actions are essential programmes for any such laboratory.

Such research, he believes, provides the right blend of academic work and routine testing which allows toxicologists to develop and execute an alternative to the recipe book approach to toxicology. Furthermore it provides the laboratory with a good understanding of the advantages and limitations of tests to assess toxicity.

It is this experience which makes CTL so influential. One area in which the laboratory has had considerable impact — and particularly on the HSE — is in the field of short term *in vitro* tests for predicting carcinogenicity. A cell transformation assay developed by Dr Jerry Styles at CTL is at least as reliable as the Ames test for detecting potential carcinogens, and in fact complements it. With some known carcinogens such as Butter Yellow the Ames test fails to identify the chemicals as potential carcinogens whereas the Styles assay will do so; and the reverse is also true. On this basis, the CTL group advocates that where short term tests are used to assess carcinogencity, as a minimum requirement the two tests should be used as a screening net. The HSE is in agreement with this suggestion.

Styles and his colleage at CTL, Dr John Ashby, have recently argued that *in vitro* tests have distinct limitations and that the evidence they produce is not sufficient to allow quantitative assessments about carcinogenic potency. They are, however, ideal for use in a qualitative fashion for identification of potential carcinogens. The point was well taken by the HSE, which believes that carcinogenic potency is best assessed by long term animal studies.

With CTL bearing the responsibility for the testing of ICI industrial chemicals, some of which may be toxic and potentially carcinogenic, rigorous laboratory hygiene is essential. To achieve this CTL uses a concept pioneered by ICI to assess safety on its industrial plants — the hazard and operability (haz-op) study. Purchase reports that the studies were time-consuming, but worthwhile. They involved a detailed assessment of every stage in the testing of a chemical from its synthesis to the analysis of animal tissue following long-term feeding tests. Flow charts are constructed detailing the stages and every conceivable mishap is considered and precautions instituted, either to prevent it occurring or to contain it (for example in the case of spillage of a carcinogen). Purchase believes that this kind of analysis ought to be carried out in all laboratories dealing with toxic substances, be they chemicals, viruses or bacteria. He says that the analysis ensures far more professionalism in the laboratory.

Things are more complicated when it comes to dealing with an ICI process which involves the use of chemicals which might be carcinogenic. Although this is not a new problem for ICI, it is one which is becoming more complex. To deal with it the company as instituted an additional reviewing step in the form of a carcinogen panel. With a membership embracing the four disciplines of medicine, biology, chemistry and law, the panel meets fortnightly and since its inception in 1975 has reviewed some 150 chemicals. The panel's brief is to review all relevant data, from the literature and within ICI, and to advise on the chemicals which may pose a risk and the action that is required to deal with it.

Purchase says that the philosophy behind the actions of ICI and much of the chemical industry is that "hazards can be contained". Dr Eric Longstaff, one of the panel members, says that in 9 out of 10 cases it is an ICI division which approaches the panel for information and advice. If the carcinogenicity of a chemical is established and it is involved in an ICI process then the panel's review will probably ensure containment of the chemical.

Work at CTL embraces a far wider field than simply testing for carcinogenicity. CTL's toxicologists recognise that the need for good toxicity testing on chemicals is a fact of life, and while they admit that the ICIs of this world have the skills available to perform the tests required by Governments, their real concern is whether they have the capacity to cope with the work-load the testing will involve. The oustanding question is whether the smaller chemical companies, with fewer resources, will be able to cope too. □

correspondence

How accurate was the carat?

SIR, — The carat, a well known jeweller's measure of weight, is generally defined as the weight of a seed of the carob tree *(Ceratonia siliqua;* Leguminosae) or about 200 mg *(Webster's New World Dictionary).* It is traditional to view seeds as having very low intra specific variation in weight, and therefore not surprising to find them used as standards of commercial weight. But how reliable was this species of seed as a standard?

The carob is a small tree native to North Africa and has the largest dry and hard seed of any Mediterranean plant. In September 1978, I haphazardly collected 12 freshly fallen pods from the ground below a healthy carob tree growing in a courtyard of the Hebrew University, Jerusalem. In April 1979, the seeds were removed from the indehiscent pods and weighed. There were ten seeds that weighed only 0.07 to 0.13 g, and I discarded these seeds from further analysis because they were variously malformed and would be noticed by any discerning merchant or shopper. The remaining 156 seeds could not be sorted into groups of heavier or lighter seeds, and this set had a mean weight of 0.198 g (s.d. = 0.024), remarkably close to the supposed weight of the carat.

However, there is no reason to believe a merchant would be so stupid as to use average (randomly selected) carob seeds as balance weights. There were 48 seeds (31%) in the sample that looked normal but weighed less than 0.2 g. All a merchant would have to do is use a gravitational sorting system on a large sample of seeds to obtain a pool of carob seeds up to 25% underweight to use when making sales. The other end of the weight distribution contained 64 (41%) that weighed 0.21 to 0.24 g. These heavy seeds would have been most useful when making purchases. In short, only 28% of the seeds in a carob seed crop would have given an honest measure. This study was supported by a subsidy from the Israeli government.

Yours faithfully,

DANIEL H. JANZEN

University of Pennsylvania, Philadelphia, Pennsylvania, USA.

Science is not all whizz

SIR, — Few would disagree with your leader article (10 May, page 89) that science in the UK is depressed. More precisely, scientists who have chosen to make a career in research are depressed. The danger is that the full effects of the lack of career structure for research scientists has not yet made sufficient impact on scientific output in this country to force any action on the problem. By the time it does, it may be too late. The experienced scientists who should play a major part in research teams of the future will have been dropped by the wayside because research councils and charities are no longer prepared to take on the "burden" (as they describe it) of funding the older person.

Your challenge to the new government to find effective, creative employment for Britain's postdoctoral fellows is to be welcomed. But is it centres for "whizz-kids" that we really need? Advancement in scientific research rarely requires the flash of genius, but rather a methodical and pains-taking approach. Most research scientists are ordinary men and women of average intellect trying to do a job like any other professional. How good they are at their job depends critically on the kind of training they have received. It is about time we got away from the notion that only geniuses can produce good science, and the corollary, that only scientists of "exceptional ability" should be funded. We are not arguing for the support of mediocrity, merely the acknowledgement that scientific research, like other professional careers, should have room for a wide variety of people with differing abilities and contributions to make, not just jobs for "whizz-kids".

Yours faithfully,

SUSAN BARLOW

ARMS, Guy's Hospital, London

Physics and Ghana

SIR, — Your article (10 May, pages 96-97) rightly emphasised the relative irrelevance of electron transport in thin manganese films to scientific problems in Ghana.

However, as the supervisor of the physicist concerned during his studies, partly in Ghana and partly at Sussex on a faculty exchange, I would like to add that we also carried out an extensive literature search and correspondence with the Timber Research Association relating to possible physics-based problems in Ghanaian forestry. These formed the basis of many long discussions during his time at Sussex.

Yours faithfully,

A. D. C. GRASSIE

University of Sussex, UK.

DPAG, GMAG and the trade unions

SIR, — Reg Bird (26 April, page 776) uses the argument that, because a fatal accident occurred under the supervision of DPAG, which has no trades' union nominees, whereas no comparable accident has occurred under GMAG, which has TUC nominees, therefore the accident free record of GMAG is a consequence of this presence. It seems a pity that fallacious reasoning which would never appear in your scientific papers is allowed to exist in your correspondence columns.

Yours faithfully,

ALAN D. B. MALCOLM

St Mary's Hospital Medical School, London, UK.

Nuclear power does not lead to nuclear weapons

SIR, — Professor Rotblat with his phrase "the life blood of modern society" (31 May, page 370), recognises the need for adequate energy supplies, yet he seems reluctant to accept that nuclear power should make a contribution.

Even though his proposed World Energy Organisation would *(inter alia)* "advise countries of the type of energy most suitable for them — including nuclear if deemed necessary", Professor Rotblat's obsession with the proliferation of nuclear weapons, the extreme views he put forward in his lecture as reported in *Nature,* 1 March, page 4 ("In the long run nuclear energy is not compatible with the survival of civilisation") and his hostility towards the IAEA make it clear that nuclear power would play little part in his WEO.

Although my arguments (26 April, page 776) have failed to convince Professor Rotblat, the facts seem plain. There is no case where a country has developed nuclear explosives by diverting material from a civil power station. In the ten year period 1945-54 three countries (USA, USSR and UK) developed nuclear explosives; between 1955 and 1964 another two countries (France and China) and between 1965 and 1974 one further country (India). Over this same time span the world nuclear generating capacity grew, and by 1974 there were 54,000 MW in operation in 19 countries. There are now 100,000 MW in operation in 22 countries, and if stations under construction are also included, the figures rise to 400,000 MW in 33 countries. This indicates that there is no direct link between peaceful nuclear power and nuclear weapons. This point comes out even more clearly when it can be shown that for each of the five nuclear weapon states the explosion of their first bomb preceded, not followed, the entry into service of their first prototype commercial power reactors (Table 1).

The plutonium for the Indian nuclear explosion of 1974 was obtained from a research reactor. In addition it is widely believed that Israel and South Africa are probably capable of making nuclear weapons, but neither country has a commercial nuclear power station in operation.

It could be argued that the greater a country's dependence on nuclear energy for essential electricity the less likely it would be to jeopardise its relations with international suppliers by breaking international agreements. Quite contrary to the innuendo of Professor Rotblat's final sentence, most nations have not become nuclear weapon states: 104 of them have acceded to the Non-Proliferation Treaty.

It is essential that every effort is made to find ways to prevent the misuse of nuclear energy; a refusal to accept its benefits is not one of them.

Yours faithfully,

G. H. GREENHALGH

A Power for Good, London, UK.

Table 1 Dates of first nuclear bomb and first nuclear reactor for the five nuclear weapon states

Country	Date of first bomb exploded in atmosphere	Date of first prototype power reactor in service	Commercial name
USA	1945	1957	Shippingport
USSR	1949	1958	Troitsk
UK	1952	1956	Calder Hall
France	1960	1964	Chinon
China	1964	No firm evidence of a power reactor in service

news and views

The legacy of Xenophon

from Robert W. Cahn

THE US National Academy of Sciences gave the name COSMAT to a massive study it sponsored of the profession of materials science and engineering (MSE), published in five thick volumes in 1974 and 1975. It is a remarkable compilation; because of its wide terms of reference, and especially because of its historical and international emphasis, it is of value far beyond the originally intended readership in its target profession. The report is difficult to locate and few people in Britain have read it, and to make at least a small extract accessible to a wider readership, a learned periodical, appropriately named *Materials Science and Engineering*, has published a special issue entirely devoted to a revised and updated version of two chapters from one of the volumes (*Materials Science and Engineering: Its Evolution, Practice and Prospects*, Elsevier-Sequoia, March 1979).

The heart of the extract is a forty-page essay, by Melvin Kranzberg (editor of the journal *Technology and Culture*) and Cyril Smith (the world's leading scholar in the history of metallurgy), on 'Materials in History and Society', complete with a bibliography of 85 items which alone would justify acquisition of the volume. The emphasis is predominantly on the history of the use and understanding of metals. The essay is a masterly examination of the ways developments in the manufacture, purification, variegation and fitness for purpose of materials influenced, not only the tenor of daily life, but matters of great social impact such as the spread of agriculture; the balance of affluence between patricians and plebians (as 'aristocratic' bronze gave way to 'democratic' iron); the spread of the printed word and the printed image; the materials testing institutions which were a precondition of safe machinery and all that implies. The later parts of the essay are more concerned with the gradual development — remarkably delayed, and significant only in the twentieth century — of a scientific and analytical approach to materials. Réaumur, in the early eighteenth century, was the first modern materials scientist, but his ability to relate traditional practice to advanced science was not followed, for the love of mathematical physics applied to highly simplified models was at that time irresistible and the obscurantism of the alchemists had repelled the disciples of Newton.

Kranzberg and Smith's survey is followed by a section with its eyes wholly on modern times: Richard Claassen and Alan Chynoweth, two industrial scientists, write on 'MSE as a Multi-discipline'. Specifically, they trace the routes by which physicists, chemists and engineers of various persuasions combined to create the profession of MSE, and they do so primarily through a collection of case histories of technical developments (heatshield design for space vehicles; the development of the transistor; plastic coatings on razor blades; artificial fibres; optical lightguides, and others). These stories, combined with an analysis of the implications for the organisation of interdisciplinary research projects, provide the flavour of this section.

Kranzberg and Smith, the historians, quote the Greek historian Xenophon ("What are called the mechanical arts carry a social stigma and are rightly dishonoured in our cities") and Plutarch ("For it does not of necessity follow that, if the work delight you with its grace, the one who wrought it is worthy of esteem"), to indicate what the ancients thought of craft and skills applied to materials. Of all the ancient exponents of the 'mechanical arts', the slave miners of antiquity were perhaps the most abjectly oppressed, miserable and shortlived.

Today, once again, 'mechanical artists' and miners in particular are apt to be regarded by wielders of temporal power as the carriers of social stigma. This surprising conclusion emerges with great clarity from another recent publication, the proceedings of the 1978 American Mining Symposium, the subtitle of which was 'Politics, Society and the Mineral Industry'. The proceedings are published in *Materials and Society* (**3**, 1; 1979). Several of the lectures are germane to the matter in hand: these are written by a metallurgist, a congressman, a copper mining expert, a coal mining expert and J. Allen Overton, the president of the American Mining Congress, who finds himself under the necessity of acting as a fulltime lobbyist. Their complaint — the word is too weak, it is a succession of cries of despair — is the unchecked growth of regulation and of the body of state employees who enforce regulations and steadily add to their number. The chairman remarked that the 'political outcry' as he termed it, at the symposium was unpremeditated and uncolluded and the more credible for it. The tone is exemplified by two extracts from Allen Overton's lecture: "Time and again, we see no attempts to consider trade-offs or weigh the cost of regulations against their supposed benefits. This is the work of zealots, and the only guideline they know is their own self-proclaimed virtue. The repeated failure — I should call it the obstinate refusal — to take acount of the economic consequences mean that some regulations can have ruinous impact.". And again: "Finally, there is bewilderment and foreboding about the sheer mass of regulations, their frightening complexity, the paralysing uncertainty about what the bureaucrats will propose tomorrow, and how the rules will be changed in the middle of the game ". The changing of rules in the middle of the game is exemplified by William Simon, a former US Secretary of the Treasury, in another recent publication (*A Time for Truth*, McGraw-Hill, 1978): "Manufacturers of children's sleepwear were forced by the government to process children's sleepwear with a flame-retardent chemical. When the companies shifted over to the costly new process, the FDA banned the flame-retardant chemical as a suspected carcinogen, and the manufacturers were ordered to recall their merchandise and to compensate buyers".

In such an atmosphere, it becomes understandable why American oil policy is in such disarray: those who fully understand the situation in prospect plead for decontrol and a partial release from the burden of regulation (McKetta's lecture on American energy policy at the symposium is a case in point), but their

Robert W. Cahn is Professor of Materials Science at the University of Sussex.

© Macmillan Journals Ltd 1979

word is widely distrusted by politicians precisely because they are experts. Xenophon stalks among us again. The proponents of regulation, and those who support and encourage them, are all too often convinced that experts are venal and devoid of public spirit (just as the free citizens of ancient Greece regarded their bonded craftsmen). When the mining specialists plead public interest, the fact that the plea comes from them at once invalidates it. But the inevitable consequence is that the same judgment is being applied to the regulators themselves: they have by now as great an interest vested in the increase of regulations as the protesters have in their abatement. Not only that: those miners, MSEs, and may others to whom by implication Xenophon's cold dictum is attached, conclude that their honesty is disbelieved by some of the most powerful in the land, and when a professional's integrity is systematically impugned, he is driven at last towards political extremes; at the least he will come to distrust the regulators' own honesty of purpose. The prospect is not enticing, and the American crisis of regulations should give us in Britain pause. □

Aetiology of natural scrapie

from H. B. Parry

THE crux of the problem raised by Kimberlin recently in News and Views[1] is the principal means by which natural scrapie of sheep is disseminated. My report[2] which stimulated him, was confined to providing new evidence for a heriditary factor and to demonstrating a new practical means of genetic control under current agricultural practice. Kimberlin's account[1] summarising the published laboratory studies of his colleagues[3] widens the issue of aetiology without considering relevant evidence from the epidemiology of the natural disease or from the possible pathogenesis of the characteristic sequential localised neuronal decay.

There are two main aetiological factors. First, a neurotoxic agent is present in the tissues of animals with the pathological lesions of scrapie and is transmissible artificially[4]. This is commonly called a 'slow virus', or more accurately a transmissible spongiform encephalopathic agent (TSEPA) from the pathological nature of the special neurotoxic damage developing in inoculated animals. In the absence of any reliable means of detecting the TSEPA in the living animal, we have no data on the occurrence of the agent in any sheep population. Second, there is a hereditary factor, probably a single autosomal recessive gene, with an 'all-or-none' effect on the development of the primary neuronal decay, for which no simple peripheral 'marker' reaction is known. However, indirect inferences of the gene's likely presence can be made on the basis of the results of test-mating procedures and meticulous breeding records[1].

Without such data, assessments of recessive allele frequencies are notoriously hazardous when based solely on the statements of individual flockowners and shepherds[5-7]. In my view the term 'scrapie-free' should mean free of the scrapie-allele, at least to a probability of less than 1 in 100; such sheep are available.

Spread of scrapie

The inferences of natural spread among experimental flocks, quoted by Kimberlin, are contrary to my field experience within breeding groups. Using recording methods designed to reveal such spread, I detected none, which is in accord with the evidence of many reliable observers since 1750[5-7] and with the results of other less well controlled current field observations. No spread has followed the introduction since 1950 of British sheep, which developed the disease, into certain countries that are free of the disease and have not operated any quarantine or slaughter policy. One therefore seeks possible explanations for the anomalous conclusions quoted by Kimberlin. There are four main considerations.

First, the data he quotes relate to four British sheep breeds, all of which have had substantial scrapie attack-rates at some period since 1900 and three very seriously in some sectors of their breeds since 1950 until the present time. In these circumstances the designation 'scrapie-free' applied to a sheep, a flock or a breed without meticulously supervised and relevant records, covering at least one decade before and continuously during the experimental period, lacks any precise scientific meaning. This is because the TSEPA cannot be detected and the recessive scrapie allele is likely to be widespread but clinically 'silent' in these breeds and may at any time without prior evidence reach frequencies leading to clinical manifestation[2]. Thus the group designated 'scrapie-free' is likely to consist of mixed populations of the three genotypes. The authors quoted by Kimberlin provide no indication that the proper safeguards against these possibilities have been enforced. The meaningful interpretation of results from such populations on the present evidence is thus not possible.

The second consideration is that the results quoted are commonly presented as totals of all matings between so-called 'scrapie-free' and 'scrapie-affected' groups without any attempt to assess presumptive recessive genotype frequencies in each group. Third, the aggregation of the results of different sire-progeny groups as accumulated totals masks information relevant to their proper evaluation, for example, the possible proportions of the three recessive genotypes and allele frequencies in different sectors of the breeding population, the degree of in-breeding, occurrences of associated sub-normal health and reproductive efficiency, which may affect the totals manifesting scrapie and their ratios. Fourth, the American experience, quoted by Kimberlin, kindly made available by Dr. J. L. Hourrigan, when analysed, as far as the data allow, on a provisional genotype basis, are approximately compatible with my own. I therefore have serious reservations of the validity of the conclusions derived from the experimental flocks quoted as evidence for the normal dissemination of natural scrapie by the spread of a communicable agent.

Artificial scrapie and genetic control

The artificially induced form of scrapie disease is probably not identical to the natural form and the precise transferring of the results of the one to the other is questionable. In most of the studies quoted by Kimberlin the source of inocula of scrapie TSEPA material designated SSPB/1 was derived from 40 affected sheep brains. After 20 years this is now very much more toxic than any TSEPA we have been able to demonstrate in the natural disease on first transfer.

These reservations do not preclude extrinsic factors operating in natural scrapie, merely that their possible occurrence requires more precise definition. Any aetiological hypothesis must also provide an acceptable explanation of the specific characteristics of the neuronal degeneration in the natural disease[8]. □

Photogenic impurities

from Henry Slayter

TWO papers, published together in the *Journal of Biological Chemistry* (**254**, 1747; 1979) come essentially to the same conclusion concerning the structure of pyruvate carboxylase examined by electron microscopy. Goss *et al.* of the University of Adelaide and Cohen *et al.* of Case Western Reserve and the National Institute for Medical Research, London, have both applied negative staining to this molecule, obtaining different results from those previously reported by Valentine *et al.* (*Biochemistry* **5**, 3111; 1966) using the same technique. (Two of the coauthors of the latter group were also coauthors of the original Valentine group.)

Negative staining was first described and applied by C.E. Hall and later applied skillfully and to great advantage by many investigators (including, especially, Valentine and R.W. Horne) in the study of biopolymeric structures. In this method, the purified preparation is mixed with concentrated electron-dense 'stain', usually a 1 — 5% solution of uranyl acetate, uranyl formate, sodium phosphotungstate or sodium phosphomolybdate. The preparation is air-dried to form a thin layer supported on 10-nm carbon films. Stain, which is excluded by biopolymer components, penetrates voids, thus outlining the structure. Electron contrast results from the greater electron scattering power of the stain (average density about 7) compared with that of the specimen.

Inherently, this technique is a simple and effective method for examining macromolecules larger than about 5 nm in diameter — but pitfalls abound. Resolution is limited by granularity of the stain, alteration of specimen structure by dehydration, extent to which contrast can be induced in small subunits, and, to an indeterminate extent, specimen damage in the electron beam. Other difficulties relate to the effects of these rather unusual chemical salts on the specimen (due to *p*H and ionic strength requirements, the reducing nature of the salts, the presence of divalent cations and so on). Penetration of the specimen by stain can produce misleading measurements of dimensions or loss of fine structure. As in any method for the examination of individual macromolecules, absolute specimen purity is vital.

Valentine *et al.* originally described the pyruvate carboxylase molecule as a distinctive square-planar tetramer of globular subunits. Several lines of evidence supported this premise. The highly photogenic square-planar configuration appeared in enzyme preparations isolated from several animal species. Dimensions obtained by electron microscopy were consistent with the measured molecular weight of 500,000, consisting of four similar or identical subunits of molecular weight 125,000. The square-tetramers exhibited cold-lability, a well characterised property of chicken liver pyruvate carboxylase.

Valentine, however, also showed that the same enzyme from yeast had a rhombic appearance (Valentine, *Proc. fourth Regular Conf. (Europe) on Electron Microscopy, Rome* **2**, 3; Tipografia Poliglotta Vaticana, Rome, 1968). Now, the new reports show that a similar structure characterises pyruvate carboxylases of animal origin, and that the square-planar molecule is a contaminant commonly found in such preparations. That this contaminant was so much more evident than the enzyme itself is explained, in part, by the demonstration of Goss *et al.* that this structure is actually an octamer in which the thickness (and therefore the relative contrast) of each subunit is doubled.

Both new studies confirm that pyruvate carboxylase consists of four subunits. Cohen *et al.* suggest a rhombic structure with major and minor dimensions of 19 nm and 16 nm respectively, and a centre-to-centre distance between adjacent subunits of 7.3 nm. (They report that exact dimensions vary by as much as 10 % depending on the substance used as negative stain.) Goss *et al.* describe the molecule as a 'splayed tetrahedron' with a long axis of approximately 17.7 nm and a short axis of 15.2 nm with centre-to-centre distance again 7.3 nm. The main difference between the two interpretations is whether the subunits lie in a plane (rhombic structure) or are without regular mutual separation and are not coplanar (splayed tetrahedron).

Cohen *et al.* indicate that their data cannot be fully interpreted with regard to the question of subunit arrangement in three dimensions, but Goss *et al.* suggest that one pair of subunits is displaced slightly above the plane of the second pair. Examination of the field of negatively stained molecules presented by the latter authors shows that only a small number of images can be so interpreted. Thus, while their speculative model is most interesting, I must admit difficulty in accepting with certainty either the proposed three-dimensional arrangement or the detailed tear-drop model of subunits. Further understanding of the structure of this enzyme must await preparation of crystals and their examination by iterative electron microscopy or X-ray crystallography.

Anti-biotin antibody and pyruvate carboxylase are known to form soluble complexes. Cohen *et al.* also present micrographs of this complex, which indicate that the antibody binds to the surface of the tetramer at the same general location as does avidin. Thus, additional evidence is presented that the rhombic tetramers are in fact a biotin-containing protein.

In perspective: some will remember that similar interpretive difficulties have arisen in past studies of negatively stained enzyme preparations — brought on, likewise, by impurities of a significantly more photogenic character than the plainer principal subject. (DNA-dependent RNA polymerase, first reported to be amorphous globular protein, was credited by a second group with a distinctive polyhedral structure. A third group showed up the polyhedron as a mere contaminant and found the polymerase to be an amorphous globular protein.)

What can be learned from all this — perhaps — is that while carefully applied electron microscopy can be of tremendous and unique importance in providing structural information, interpretation must always be carried out with extraordinary care. Awareness of the artefacts to which biopolymers are prone is a must, and investigations should include parallel studies in solution which pose the same questions asked of the electron microscope. Above all, very careful attention must be given to the purity of the preparation. Even a few per cent of contaminating molecules, especially those of the more photogenic sort, can — given the harsh treatment inherent in this method — be interpreted as being a few per cent of survivors of the structure sought. □

Budgeting for volcanoes

from Peter J. Smith

WHAT is the energy budget of a volcano? Or to be more explicit, what proportions of a volcano's energy are carried away by the various modes of energy transport? What, for that matter, are the appropriate transmission mechanisms? These are the sort of conceptually simple questions one would expect some nineteenth century volcanologist to have answered, albeit incorrectly; but whether he did or not, the same questions are still being asked in 1979, possibly because they are not as easy to come to terms with as might be supposed. Certainly they are not answered entirely satisfactorily by McGetchin and Chouet (*Geophys. Res. Letts.* **6**, 317; 1979) even now, as these authors freely admit.

But to start at the beginning, for many years McGetchin and Chouet have been studying the behaviour of Stromboli, the famous volcanic island that rises about 920m above the Mediterranean some 75km

0028-0836/79/270013-02$01.00

© Macmillan Journals Ltd 1979

north of Sicily. Since records began this volcano has been in a "more or less continuous state of episodic activity, characterized by well-collimated jets of incandescent gas loaded with molten fragments of basaltic vitric lapilli" — a characteristic "fire-fountaining" type of activity that has come to be known as Strombolian though not limited to Stromboli. In jargon, this is known as the volcano's "normal mode", the "steady state episodic mode"; and it is with this type of behaviour that McGetchin and Chouet are chiefly concerned.

No reliable heat flow values have been obtained in the vicinity of Stromboli; but from their own downhole temperature measurements, McGetchin and Chouet estimate that above sea level the volcano is emitting something like 6 MW in the form of heat conducted up through the ground. This is about 84 % of the total energy emitted. By comparison, all other forms of energy transmission are small and most are negligible. Next in magnitude comes the heat carried by ejected gas (700 kW, or 9.8 %), then the heat carried by ejected particles (2.8 %) and the heat radiated from the vent (also 2.8%). Seismic energy released amounts to 0.42 % of the total. Finally there is the kinetic energy of ejected gas (0.0091 %), acoustic power (0.0014 %) and the kinetic energy of ejected particles (0.00034 %).

Needless to say, these estimates depend on assumptions and are therefore open to correction. But even if the results are perfectly accurate, the conclusions that McGetchin and Chouet reach are highly dubious, as they themselves note. The most significant phrase in the last paragraph is probably "above sea level". The fact is that Stromboli is largely submarine; yet the underwater region has been ignored, and with it the large amount of heat likely to be transferred by the convective power of circulating groundwater.

The question of the "normal mode" of volcanic activity is also crucial. It is well known that from time to time Stromboli departs from its usual behaviour and undergoes violently explosive eruption. During the explosive eruption of September 1930, for example, the mass of material ejected was equivalent to that produced during 300 years of normal activity. These violent phases, though unusual in the duration sense, strongly influence the energy/mass equation. So should they be included in the sums, or ignored on the grounds that they are atypical?

On the face of it, McGetchin and Chouet seem not to have achieved very much so far; their figures are, at best, misleading and in any case refer only to one type of behaviour from one particular volcano at one particular period. On the other hand, they have gone some way towards the solution of a fundamental scientific problem, demonstrating in the process that the simplest questions to formulate are not necessarily the easiest to answer. The issue may also be of practical importance to the extent that volcanic heat is being investigated as a possible source of geothermal energy. □

Assessing effects of marine pollution

from B. L. Bayne

STUDIES of the chemical and biological aspects of pollution should go hand in hand. The chemical assessment of estuarine and marine pollution involves the analysis of water, sediments and biota to determine the levels of contaminants in the ecosystem. Because of technical difficulties of analysing water and sediments (Phillips *Env. Pollut.* **13**, 281; 1977), chemical monitoring is usually concentrated on the biota to provide time-averaged values for the biologically available contaminants (Goldberg *et al. Env. Conserv.* **5**, 1; 1978). The biologist is therefore given the dual responsibility of elucidating the effects, if any, of the observed levels of contaminants in living material, and co-ordinating his efforts with those of the chemist in order to provide an overall assessment of environmental quality.

It is not surprising, therefore, that there has been a recent increase in interest in procedures for measuring the biological impact of pollution (International Council for the Exploration of the Seas (ICES) Cooperative Research Report 75, 1978; *Phil. Trans. R. Soc., Lond.* **286**, in the press; ICES Workshop on Pollution Effects Monitoring, in the press). Much of the considerable research effort is based on the effects of pollution on the individual organism; from this work two general points have emerged which facilitate the planning of further research.

First, the non-specific effects of pollution can generally be characterised in terms of a stress syndrome following the paradigm of the general adaptation syndrome of Selye (*Stress*; Acta Inc., Montreal, 1950). This syndrome includes physiological (mostly involving energy gains and losses, and hormone balance), pathological and biochemical responses, the details of which may vary between species, but which, taken together, make possible a quantitative assessment of animal health that can be used to rank different populations according to the biological impact of environmental changes (Bayne *et al. Phil. Trans. R. Soc., Lond.* **286**, in the press). It is axiomatic that the observed biological responses must constitute reduction in ecological fitness for a pollution effect to be registered.

The second general point to emerge from recent studies is the widespread occurrence of mechanisms of detoxification in marine (and other) organisms. These include the cytochrome P450-linked mixed function oxidation reactions (Bard and James *Biochem. biophys. Perspec. mar. Biol.* **4**, 126; 1978), the production of metal-binding proteins, or metallothioneins (Brown *et al. Env. Conserv.* **4**, 213; 1977) and various cytological mechanisms, such as lysosomal encapsulation, that sequester some foreign compounds (Allison in *Lysosomes in Biology and Pathology*, ed. Dingle and Fell **2**, 178; Elsevier, Amsterdam 1969). These are specific responses to particular classes of contaminant and they can provide evidence of the causative agents involved in situations where measurements of the general stress effects indicate a decline in animal health. The concept of linked non-specific and specific effects of environmental agents is consistent with attributes of the general adaptation syndrome.

It has therefore become possible, by making certain measurements of the general stress response of animals, and by linking these on the one hand to measures of potential detoxification processes and on the other to the results of chemical analyses of the body burden of contaminant, to assess the impact of pollution on the organism. However, the transition from laboratory demonstrations of this kind to practical involvement in environmental management is complicated by the problem of biological variability. The response of the individual organism is seldom a simple function of the intensity of the pollution 'stimulus', because the reactivity of the animal may vary, depending on a combination of intrinsic and extrinsic factors. This inherent variability must at present be accommodated in sample design, by optimising the sampling strategy over time and space.

The merit of such studies on individuals, however, is the early warning that can be signalled concerning environmental impact; individuals respond to sub-lethal stressors long before the effects are apparent in the population or ecosystem. Nevertheless, there is an urgent need also for studies on pollution effects at the level of the ecosystem, if

only because the problems of variability at the level of organism or population may thereby be reduced (Mann and Clarke *J. Fish. Res. Bd Can.* **35**, 791; 1978). Attributes of ecosystem function that may warn of impending damage are few at present. Indices of diversity and species richness, although controversial, have been effective in some circumstances (McIntyre in *Ecology of Marine Benthos*, ed. Coull, 301; University of South Carolina Press, Columbia, 1977; Sanders *J. Fish. Res. Bd Can.* **35**, 717; 1978.). Greve and Parsons (*Helgol. Wiss. Meeresunters.* **30**, 666; 1977) have discussed the implications of a change in the ratio of diatoms to flagellates as an index of pollution effect, and Gray (*Phil. Trans. R. Soc., Lond.* **286**, in the press) has postulated that changes in the form of the cumulative species distribution curve indicate the effects of environmental disturbance. Measures of the productivity of various trophic levels, and of various size-fractions of the fauna, in both the pelagic and the benthic components of the ecosystem, may also be useful.

Further research is urgently needed and can be framed in certain generalised notions of biological response to stress. When this is coupled with better chemical understanding of the form and the biological availability of pollutants, it should be possible to provide integrated measures of environmental quality as a basis for legislation. □

Alpha-particle mode dominates giant resonance decay

from P. E. Hodgson

A GROUP at the National Bureau of Standards in Washington DC has recently made an important advance in an old technique, the use of virtual-photon spectra to determine the multipolarity of nuclear excitations (Wolynec, Dodge & Hayward *Phys.Rev.Lett.* **42**, 27; 1979). This has been used to study the nickel isotopes, and has led to the surprising conclusion that alpha-particle emission is the dominant decay mode of the E2 isoscalar giant resonance.

It is well known that when electrons are decelerated, for example when they are deflected by passing through a nuclear field, they produce photons, a process known as bremsstrahlung. These photons may be absorbed by the nucleus itself, initiating a nuclear reaction. In this case the photons are not emitted, and are referred to as virtual photons. The theory of these processes is well understood, and it is possible to calculate the virtual photon spectra associated with the excitation of the E1 and E2 giant resonances, and hence to determine the energies and strengths of these resonances from the measured yield curves. The accuracy of these analyses has now been increased greatly by the use of the distorted wave Born approximation to calculate the spectra of the virtual photons.

In the new experiments, targets of the nickel isotopes ^{58}Ni, ^{60}Ni and ^{62}Ni were bombarded with electrons from 16 to 50 MeV, and the yields of protons and alpha-particles were measured at 48°, 90° and 132°. The spectra of these decay particles peak at 5 MeV for protons and at 8 MeV for alpha-particles, and have the asymmetrical shape characteristic of emission at energies around that of the Coulomb barrier.

The total cross-section for proton emission as a function of electron energy is shown in Fig. 1, and it is compared with calculations using the E1 virtual photon spectrum and the (γ,p) cross-section known from another experiment. The excellent agreement between the curve A and the experimental data supports the correctness of the analysis.

In the second part of the experiment, a tantalum foil was interposed in the electron beam in front of the nickel target. The photons emitted from bremsstrahlung in the tantalum then cause photo-disintegration of the nickel, so that the yield from these reactions is added to the electrodisintegration yield. The cross-section for the emission of protons with this foil in place is also shown in Fig. 1 (curve B), and agrees with the calculated sum of the electrodisintegration and photodisintegration cross-sections.

The cross-section for the emission of alpha-particles was measured in the same way, and the results are shown in Fig. 2. As

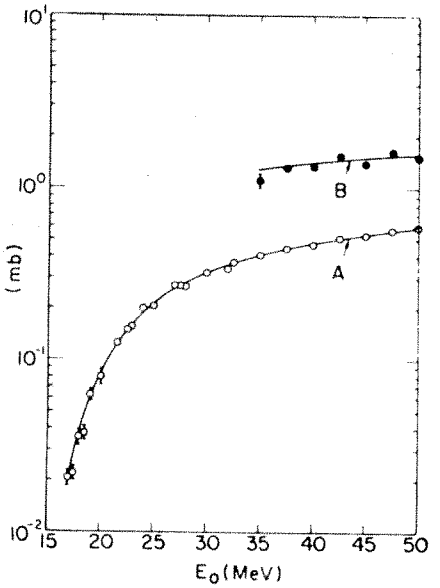

Fig. 1 Total cross-section for the production of protons as a function of the energy of the electrons incident on a ^{58}Ni target. The curve marked A refers to the case without, and B to the case with, a tantalum foil.

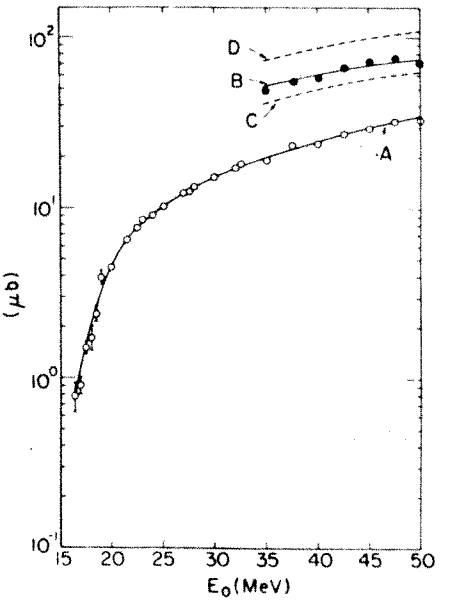

Fig. 2 Total cross-section for the production of alpha-particles as a function of the energy of the electrons incident on a ^{58}Ni target. The two sets of results are as in Fig. 1, and the assumptions made in obtaining the curves B, C and D are described in the text.

before, curve A refers to the measurement without the tantalum foil, and curve B to that with the foil. In the latter case there are three calculated curves: B was obtained using the E1 and E2 virtual photon spectra, C using the best E2 fit and D with the best E1 fit. Of these curves, only B agrees with the data, showing that both the E1 and E2 components must be included to fit the cross-section for alpha-particle emission.

These analyses show that the E1 components in the (γ,α) reaction have an energy of about 20 MeV and width of 6 MeV and account for only about 1% of the E1 absorption cross-section for each of the nickel isotopes. The E2 components have similar energies and widths, 16 MeV and 4 MeV, but account for more than half the energy-weighted isoscalar sum rule for ^{58}Ni and ^{60}Ni, and nearly a third for ^{62}Ni. Comparing with the values of 55% and 63% obtained from inelastic alpha-particle scattering for ^{58}Ni and ^{60}Ni, this leads to the conclusion that alpha-particle emission is the dominant decay mode for the E2 isoscalar resonance.

This is a very striking result, and it suggests that the E2 giant resonance has in some sense an alpha-particle structure. One possibility is that it consists of an alpha-particle coupled to a nuclear core. To test such a possibility, it will be necessary to make detailed calculations to see if it is in agreement with the experimental data. This latest application of the virtual photon method will certainly stimulate further studies to improve its accuracy and to apply it to other nuclei. □

Virus evolution during persistent infection

from C. R. Pringle

IN certain circumstances cells in culture can survive infection by viruses which normally kill them, and the cells continue to multiply still harbouring the infecting viral genome. Nuclear DNA viruses and reverse transcribing RNA viruses persist by integration into the host genome, or by regulated association with the host cell nucleus. The phenotype of the cell may be changed as a consequence and the cell may become oncogenic. However, many cytocidal RNA viruses like the rhabdoviruses and parainfluenza viruses which multiply entirely in the cytoplasm are able to establish a persistent infection in susceptible cells. The molecular mechanisms concerned in the moderation of normally lethal infections in which there is no nuclear involvement are attracting increasing interest. Three factors have been associated with persistent infection. These are temperature-sensitive (*ts*) mutation which impairs virus replication at normal incubation temperature, defective interfering (DI) particles which have portions of the viral genome deleted and suppress the multiplication of homologous complete virus, and production of interferon. The most recent analyses indicate that these factors are interdependent, and that interferon production may hold the balance. Sekellick and Marcus (*Virology* **85**, 175; 1978; **95**, 36; 1979) have shown that many *ts* mutants of the rhabdovirus vesicular stomatitis virus (VSV) are good inducers of interferon in competent cells at restrictive and semi-permissive temperatures, and that the ability of DI particles to protect cells from the lethal action of infectious virus (as distinct from their ability to inhibit viral replication), is mediated by interferon. Interferon levels in persistently infected cultures are usually low, but addition of anti-interferon serum frequently results in an increase in virus production and cell destruction (Youngner *et al. J. Virol.* **28**, 6 1978; Ramseur and Friedman *Virology* **85**, 253; 1978). However, persistent infection can be established in cell lines such as Vero and BHK-21 which are genetically deficient in some component of the interferon system. Another important factor may be the progressive selection of a population of semi-refractory cells, because a change in karyotype has been observed in a culture of BS-C-1 cells persistently infected with respiratory syncytial virus (Pringle *et al. J. Virol.* **28**, 199: 1978).

C. R. Pringle works at the MRC Virology Unit, Institute of Virology, Glasgow.

0028-0836/79/270016-01$01.00

Persistent infection has been given new significance by the results of surveillance over five years of a BHK-21 cell culture persistently infected with the Indiana serotype of VSV, with oligonucleotide fingerprinting used to detect changes in the genetic constitution of the virus (Holland *et al. Cell* **16**, 495; 1979). The data reveal that the virus has undergone extensive and progressive non-lethal mutational change during this period. The implication is that the mechanisms which moderate virulence to produce persistent infection may simultaneously promote rapid virus evolution.

VSV seems to be genetically stable during repeated cycles of lytic infection. Clewley *et al.* (*J. Virol.* **23**, 152; 1977) found that strains of VSV derived from different field isolates were readily distinguishable by oligonucleotide fingerprinting, although most of the oligonucleotides were conserved. On the other hand one strain maintained independently in six laboratories for 16 yr was unaltered. Likewise Holland and his colleagues could detect no changes in their strain of VSV after eight sequential cycles of cloning in BHK-21 cells, forty cycles of lytic infection in the same cells, and five lethal infections of adult mice. The virus also remained unaltered after growth for 2 months in *Aedes albopictus* cells, although passage in insect cells was known to generate high freequencies of *ts* mutants. These results are not unexpected, however, because 85–90% of all sequence changes would not be detectable by oligonucleotide mapping, because only the larger oligonucleotides (10–15% of the total) obtained by T1 ribonuclease digestion would produce unique spots after polyacrylamide gel electrophoresis in two dimensions.

A very different pattern was observed in the persistently infected culture. This carrier culture had been established by a maturation-defective *ts* mutant of VSV (*ts* G31) in the presence of a DI particle derived from this same mutant. Thus all the genome alterations observed in this culture were a consequence of mutation in the progeny of a single virus particle. The DI particle associated with *ts* G31, which is the smallest of the VSV DIs with approximately 90 % of the genome deleted, was considered to be an essential factor in establishing persistence, although during propagation of the culture it was subsequently replaced by a succession of other DI particles. These DI particles had different oligonucleotide patterns from the original DI of *ts* G31. Infectious virus recovered from the culture after continuous propagation for 14, 21 and 42 months showed 5, 8 and 11 map changes, respectively. At any particular time one DI particle predominated and different clones of infectious virus isolated from the culture at the same passage level had identical oligonucleotide patterns. Because 90 % of sequence changes would have occurred in the non-unique small oligonucleotides, it is clear that at least 50–100 mutations had occurred by 3.5yr, although only a proportion would result in changes in the amino acid composition of the viral proteins. Nevertheless, it was evident that the VSV genome had experienced extensive and progressive mutational change during persistent infection. The genome changes induced by persistent infection seemed to be stable because virus isolated from the carrier culture after 5yr showed no alteration during ten cycles of lytic infection in susceptible cells.

These observations suggest that persistent infections are a major source of genetic variation for viruses like the parainfluenza viruses and rhabdoviruses, which are unable to acquire new variation by recombination. Holland *et al.* also suggest that persistent infection is an important factor in the evolution of influenza A virus. A given strain may show little variation during periods of acute infection, and extensive sequence alterations (with or without reassortment of subunits) may only accumulate in the interval between pandemics when the virus is sequestered in foci of persistent infection in individual hosts.

One of the most interesting properties of these carrier cells was that they could be propagated in nude (athymic) mice, and it was observed that persistent infection by VSV suppressed the normal tumorigenicity of BHK-21 cells (Reid *et al. J. gen. Virol.* **42**, 609; 1979). Analysis of this anti-tumour response may shed light on the difficulties encountered in propagation of certain types of human and other tumours in nude mice. □

A hundred years ago

Intellect in Brutes

The following instance of sagacity in a cat has just been related to me by a friend who knew both the cat and its owner well. The latter, who lived at Ragusa Vecchia, in Dalmatia, was too poor to be able to provide food for the cat; the animal was therefore obliged to cater for himself, and was well known as a thief in the neighbourhood. One day one of the children was being sent off to school without any breakfast; the cat, hearing him sobbing for hunger, immediately went off, and returned with a piece of bread he had stolen from a baker hard by, and brought it to the child. The same thing happened another day, and he came back, dragging along a piece of meat bigger than himself. On crossing the threshold a bit of bone caught in a hole, so puss miawed till some one came to his help. This same cat, who was constantly catching birds on the roof, slept with some pet birds in a cage without attempting to touch them.

A unifying model for the G1 period in prokaryotes and eukaryotes

Stephen Cooper
Department of Microbiology, The University of Michigan School of Medicine, Ann Arbor, Michigan 48109

A model to explain the cell division cycle in both prokaryotes and eukaryotes is presented. No specific 'G1 functions' take place during the G1 period, which is merely part of a larger period for the preparation of DNA synthesis which began at the previous initiation of DNA synthesis. A G1 period exists merely because the doubling time of the cells is greater than the sum of the S and G2 periods.

THERE was a time, a few years ago, when the division cycles of prokaryotes and eukaryotes could be clearly distinguished. The division cycle of eukaryotes consisted of three periods—G1, S and G2—whereas prokaryotes had only C and D periods (analogous to the S and G2 periods, respectively) but did not clearly exhibit a G1 period. The S and C periods are analogous when defined as the time of DNA synthesis, and the G2 and D periods are analogous when defined as the time between the termination of DNA synthesis and mitosis or cell division. The analogy between the S and G2 periods and the C and D periods was strengthened by the observations that the lengths of time for these periods were quite invariant with large changes in the growth rate of the various cells[1–10]. More recently, however, it has been shown that prokaryotes can have a G1 period[11] and that there are eukaryotic cells which appear to be devoid of a G1 period[10,12–15]. Is there then any common, unified basis for understanding eukaryotic and prokaryotic division cycles?

There have been two different ways of analysing the division cycle of cells, one based on the classic results with eukaryotes and one based on the results obtained with prokaryotes. I believe that this schism is unnecessary and that there is a simple and encompassing view which allows both types of division cycle to be discussed in the same terms. My main premise is that there is no physical reality to the G1 period which requires that it have any particular function; instead the G1 period is merely part of a larger period involved in the preparation for DNA synthesis. This leads to a common, unified model for the cellular division cycle.

Bacterial division cycle

The bacterial division cycle is illustrated schematically in Fig. 1. The C and D periods, analogous to the S and G2 periods, are 40 and 20 min, respectively. That is, it takes 40 min to replicate the DNA of the cell, and there is a period of 20 min between termination of replication and cell division. Figure 1 illustrates the relative rates of DNA synthesis in the cells (the rate being proportional to the number of DNA growing points). Note that for cells growing with a doubling time greater than 60 min there is a G1 period as well as the S and G2 periods analogous to those in the eukaryotic division cycle. Bacterial cells, however, can grow at rates faster than 60 min per doubling. In these cases Fig. 1 illustrates that there is no G1 period. Instead DNA synthesis occurs during cell division, having started in the previous division cycle. Where the doubling time is less than 40 min DNA synthesis will commence before the completion of previously started rounds of DNA replication. These division cycle patterns are not exhibited by eukaryotes.

The particular pattern of DNA synthesis in the division cycle of a prokaryote therefore is determined solely by the frequency with which DNA replication is initiated. Once initiated, the 'clock' regulating the constant C and D periods determines the subsequent cell division. It is currently assumed that the preparations for DNA synthesis are occurring in the time gap between successive initiations of DNA synthesis. But the preparations for DNA synthesis are occurring continuously and not just in the period designated G1, which will appear when the time for the preparation of initiation of DNA synthesis (equivalent to the doubling time of the cells) is greater than the sum of the C(S) and D(G2) periods.

The nature of the factor(s) responsible for the initiation of DNA synthesis in bacterial cells is not known. Although it is quite reasonable to discuss the phenomenon in terms of a 'hypothetical initiator', circumstantial evidence points to the initiator being synthesised in the same manner as, or in parallel with, the synthesis of cell mass. Therefore, either the cell initiates DNA synthesis when a predetermined cell mass is reached or when some specific initiator, which is a constant fraction of cell mass, is present in the cell. In formal terms, DNA synthesis is initiated when the cell contains a given amount of initiator per origin of DNA to be initiated[16].

Eukaryotic division cycle

In contrast to the bacterial division cycle, the eukaryotic cycle is generally seen to fall into three divisions, a G1 period before DNA synthesis, the S phase defined as the period of DNA synthesis, and the G2 period, defined as the period between DNA synthesis and mitosis plus cell division. (In the following

0028-0836/79/270017—03$01.00

© Macmillan Journals Ltd 1979

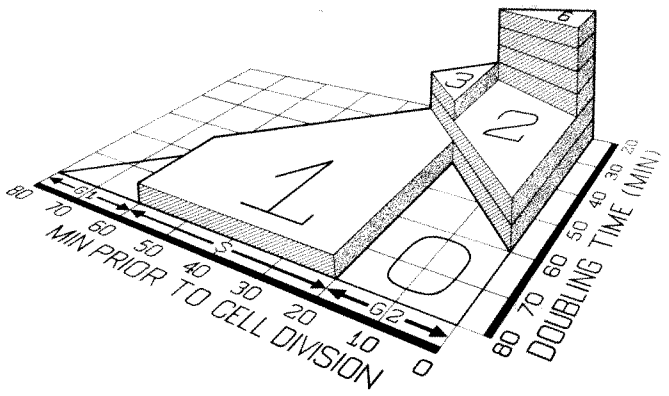

Fig. 1 Theoretical pattern of DNA synthesis during the division cycle of bacteria growing at different growth rates. The vertical axis is the rate of DNA synthesis during the division cycle. Zero DNA synthesis indicates that there is a 'gap' in DNA synthesis and this can be divided into the G1 and G2 periods as indicated. G1 and G2 periods are found when the doubling time is greater than the sum of the S and G2 periods, in this case with doubling time greater than 60 min as the S and G2 periods in *Escherichia coli* B/r are 40 and 20 min, respectively[1]. As the graph extends forward to larger and larger doubling times the G2 and S periods remain constant, and the G1 period grows. This portion of the figure is compatible with both prokaryotic and eukaryotic observations. Bacteria can grow with doubling times less than 60 min, however, and the pattern of DNA synthesis during the cycle is altered so that there is no G1 period and the late gap is shortened. The synthesis of DNA is necessarily initiated before cell division, but the time between the termination of a round of DNA replication is unchanged and remains at 20 min. Thus, between 60 and 40 min doubling times the initiation of DNA synthesis occurs during the period between termination of DNA synthesis and cell division (that is, in the bacterial G2(D) period). At doubling times of less than 40 min DNA synthesis is continuous with no 'gaps' in synthesis, and multiply-forked DNA molecules appear. Eukaryotic cells usually have doubling times which exhibit a G1 and a G2 (as in the cultures with doubling times greater than 60 min in this figure).

discussion it is assumed that there is a very small and negligible mitosis and cell division period, so the cycle is divided into only three parts.) To summarise a large amount of data, it seems that the S and G2 periods are fairly constant time periods and therefore are excellent analogues of the C and D periods of bacteria[10].

A generally current view of eukaryotic cells is that they, in contrast to prokaryotic cells, have a defined G1 period in which occur events preparatory for DNA synthesis[14,17,18]. This view is difficult to reconcile with reports that there are eukaryotic cells which are devoid of a G1 period ("G1-less cells")[14,15]. How can one have cells which have the G1 events but which do not have G1? I will answer this by presenting a simple description of the division cycle, of both prokaryotic and eukaryotic cells, which suggests that the eukaryotic G1 period has no functional significance and can disappear if the cell grows so fast that the S and G2 periods occupy the entire division cycle. In this model, the 'G1 period' is merely part of a larger period of preparation for the initiation of DNA synthesis.

Description of the general model

Consider three reactions which are observed to occur at various times in the G1 period of cells growing at such a growth rate that they have a substantial G1 period. In Fig. 2 they are indicated as a, b and c. The current (eukaryotic) assumption, that G1 is a period of preparation for S, is illustrated in Fig. 2*A*. If these cells are now grown at a rate where G1 grows appreciably smaller, S and G2 being relatively constant, then the rate of sequential appearance of the various G1 functions will increase rapidly as indicated in Fig. 2*B*. In the limiting case where G1 disappears, this model produces a paradox in that there is no G1 period during which the G1 function can take place.

The alternative model, proposed here, is illustrated in Fig. 2*C*. Here the functions a, b and c occur at precisely the same time as in Fig. 2*A* with regard to the observed G1 period but these functions are occurring as part of a longer preparation period which stretches from the initiation of S to the next initiation of S. There is no experimental or operational distinction between Fig. 2*A* and 2*C*. However, if the cells now grow at a faster rate so that G1 is appreciably shortened, then as indicated in Fig. 2*D*, the three functions a, b and c can occur earlier than G1—even occurring in S or G2 as shown in Fig. 2*D*. Where the doubling time is so short that there is no G1, the 'G1 functions' would all take place in either the S or G2 periods.

Illustrative applications of the model

Prescott[10] has summarised the large amount of experimental data on the timing of the G1, S and G2 periods in eukaryotic cells. He has even noted that "These studies lead to the conclusion that the initiation of DNA replication is tied to the attainment by a cell of a crucial mass". He has also noted how this is similar to the bacterial model briefly described above (Fig.

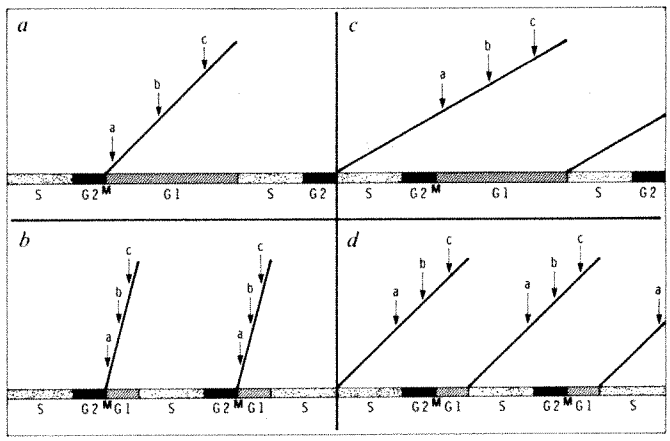

Fig. 2 Comparison of the eukaryotic view of the preparation for DNA synthesis (*A*, *B*) and the prokaryotic view of the preparations for DNA synthesis (*C*, *D*). *A* and *C* are two different interpretations of the observed preparations (a, b, c) for DNA synthesis as experimentally measured during G1. In *A* they are all part of a period of preparation for S which takes place in G1. In *C* they are part of a larger period of preparation for S which takes place from one initiation to the next, but with a, b and c only fortuitously occurring during the G1 period. *B* and *D* show how each of the models visualises the preparatory events when the rate of growth increases and the G1 period decreases in size. Although this figure is drawn as though there are different events occurring during the period of preparation for DNA synthesis, note that there is no firm and compelling evidence that the initiation of DNA synthesis occurs after a sequence of discrete reactions has occurred. The alternative view, that initiation occurs when some unitary factor has accumulated to some crucial level, is also compatible with this figure with the events a, b and c indicating the achievement of a particular level of the 'hypothetical initiator substance'.

1). I do not wish to repeat his analysis, and rather than review the mass of data on the nature, timing and events occurring in the G1 period, I will show with a few examples how the bacterial model serves to rationalise and explain the data on the nature of the G1 period better than the current eukaryotic model.

For example, Tobey *et al.*[19] have described a specific f1 histone phosphorylation event as occurring in G1 and therefore as a G1-specific event. When cells are growing more rapidly, it would be predicted (although it has not been specifically predicted or stated before, presumably because the possibility has not been studied) that the G1 events would merely occur more

rapidly leading to shorter G1 periods as seen in Fig. 2*B*. In contrast, the bacterial view presumes that the G1 events occurring in G1 are found in G1 only because G1 exists as an observable phenomenon when the doubling time of the cells is greater than the sum of the S and G2 periods. At a faster growth rate the events which may be observed previously to occur in the G1 period may now occur in the G2 or even the S period. This is clearly illustrated in Fig. 2*D*. The existence of a G1 event does not support or refute the view proposed here, but study of this phosphorylation reaction in cultures growing at different growth rates might lead to an experimental test of the unified model.

A clearer example is the analysis of eukaryotic cells which do not have a G1 period. Liskay and Prescott[15] have studied such a cell, and have obtained variants from the G1-less cell which contain a G1. They observed that the S and G2 periods did not change and that the appearance of a G1 was entirely accounted for by the increase in the doubling time of the variant cells. I suggest that this is an experimental verification of the idea that the G1 period is produced when the doubling time of a culture is greater than the sum of the S and G2 periods. When Liskay and Prescott selected for cells which had a G1 period, they were actually selecting cells which grew slower and which had less frequent initiations of DNA synthesis. The appearance of the G1 period was not due to any change in the genetic control of the G1 period itself, but merely due to the selection of mutants which had a slower growth rate without any concomitant change in the rate of DNA synthesis (S) or the rate of preparation for cell division following DNA synthesis (G2). Fusion experiments between the slow growing variant and the parental G1-less cell revealed that the variant was a "deficient condition' which is just what one would expect to produce a slow growing cell. Work by Liskay[14] had shown that the G1-less cells, when fused to temperature-sensitive mutants which had defects in their 'G1 functions', were able to complement the mutants. Therefore, the 'G1-less' cells still exhibited the G1 functions. This would normally seem paradoxical unless one subscribes to the model exhibited in Fig. 2*C* and *D* which shows that there is no special G1 period and no special G1 function. Assuming that there are functions which occur sequentially in preparation for DNA synthesis, the model proposed in Fig. 2*C* and *D* explains this apparent paradox since it is merely an accident of the cellular growth rate whether the function appears in the G1 period or not. In contrast to the model proposed here, Liskay and Prescott[15] have interpreted the G1-less cells as having 'full expression' (constitutive expression?) of the G1 functions. This is an *ad hoc* explanation which says that G1 functions can be expressed at other times. But it retains the notion of G1 functions.

Implications of the model

The model proposed here presents a unified view of the prokaryotic and eukaryotic division cycles. The main thesis is that the G1 period is merely an artificial construct of the observation, in slow growing prokaryotes and in most eukaryotic cells, of a period of cell growth and synthesis before the S period. The model described above proposes that it is more profitable to look at G1 as part of a larger period, from one initiation of DNA synthesis to the next initiation of DNA synthesis, during which the preparations for DNA synthesis are taking place.

How do eukaryotes and prokaryotes differ?—With regard to the division cycle only, the only difference between prokaryotes and eukaryotes seems to be the apparent inability of eukaryotes to synthesise DNA, that is, have an S period, at the time of cell division. This is possible for prokaryotes because the two nucleoids of the bacterial cell are self-contained and can function while the cell divides. I suggest that this is not the case for eukaryotes, where the completion of the S period produces a single nucleus with twice the diploid DNA content and which separates into two nuclei at mitosis and cell division. It is very likely that mitosis, and the associated condensation of DNA into chromosomes, is not compatible with continued DNA synthesis, and for this reason there is never any DNA synthesis during cell division in eukaryotes. If eukaryotic cells could produce two 'interphase' nuclei following the S period (for example, if the nuclei underwent an immediate mitosis without cell division), then it would be possible for DNA synthesis to occur in these nuclei while the cells were undergoing cell division. This would be analogous to bacterial cells growing with a doubling time of less than the sum of the C and D periods (60 min in Fig. 1).

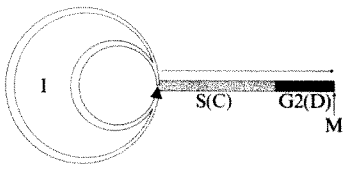

Fig. 3 A schematic representation of the cellular division sequence indicating the period for preparation of initiation, I, which is followed by the S(C) and G2(D) periods finally resulting in M (mitosis). The frequency of initiation is determined by the rate at which preparations for initiation occur, and this is indicated by the two different-sized circles, each representative of a different rate of growth. Note that the preparations for initiation occur continuously and do not start at M.

The cell division sequence—A corollary of my hypothesis is that there is no such thing as the division cycle. The word 'cycle' implies that at cell division something is initiated, the cell cycle. Actually, nothing starts at cell division but it is merely the end of a sequence of events which start with the accumulation of some initiation potential, and which was followed in succession by the initiation of DNA synthesis, the preparations for cell division following termination of DNA synthesis, and the final cell division (Fig. 3). The final cell division is the end of the process and the beginning of nothing. These ideas were expressed in relation to the bacterial cell division a decade ago[20].

The ideas described above were developed about a decade ago in discussions with many colleagues. One who deserves special mention is C. E. Helmstetter of Roswell Park Memorial Institute. At that time it was expected that the analysis of eukaryotic cells would eventually follow the logic of the bacterial analysis and therefore an explicit description of a unified model was unnecessary. This has not been the case, hence this brief article. This work was supported by grant DCM 77-14883 from the NSF.

Redshift dependence of colour and space density of radio galaxies

P. Katgert, H. R. de Ruiter* & H. van der Laan

Leiden Observatory, PO Box 9513, 2300 RA Leiden, The Netherlands

Large deep Westerbork samples of radio sources have been optically identified on Palomar Schmidt and Kitt Peak 4-m plates. The radio galaxy population shows no evolution from $z = 0$ to $z \simeq 0.25$, then rises steeply in proper density beyond that epoch, attaining enhancement factors ~ 30 at $z \gtrsim 0.5$. These distant radio galaxies show a striking blue excess of as much as two magnitudes.

IDENTIFICATION programs for samples of weak radio sources show that the apparent colours of the faint galaxy identifications (presumably at redshifts of about 0.5) are considerably bluer than expected from redshifting the spectrum of nearby giant ellipticals such as M87. From the present data we cannot decide whether these blue colours are caused by young stellar populations or by (central) non-thermal sources, or possibly both. Using the apparent magnitudes of the identified radio galaxies to derive redshifts we have determined the radio luminosity function (RLF, the space density as a function of radio luminosity) of elliptical galaxies as a function of redshift. For moderate and intermediate radio luminosities, the space density does not increase out to redshifts of 0.2–0.3. However, the space density seems to increase strongly towards higher redshifts, by factors of between 10 and 30 at redshifts of about 0.5. This increase is present even for sources of intermediate luminosities, that is just above the 'break' in the RLF. There is qualitative agreement between RLF estimates using blue and red magnitudes. However, there is a quantitative difference which can be explained if one assumes that the distant radio galaxies are intrinsically bluer than local giant ellipticals, consistent with our empirical colour determinations.

Identifications and colours

The present results are based on optical identification programs of samples of weak sources from the Westerbork Background Survey[1] (BGS) and the 3rd Westerbork Survey[2] (3rd Wbk), both defined at 1.4 GHz. These surveys comprise more than 100 fields of about 1° diameter each, distributed in an essentially random manner over the northern sky. The majority of the sources in the BGS was identified on III a-J plates taken with the 1.2-m Palomar Schmidt telescope[3]. When such plates were not available, Palomar Sky Survey prints were used[4]. For about one-tenth of the sources in the BGS, deep III a-J plates made with the Mayall 4-m telescope could be used[3]. The 3rd Wbk sample was identified on III a-J and 127-04 plates taken with the Palomar Schmidt telescope[5].

De Ruiter[6] defined a complete subsample of 785 sources from the BGS. For 155 (that is, 20%) of these sources an optical counterpart was found with $m_b \leq 21.5$ (corrected for galactic absorption). Of the 79 sources for which deep 4-m III a-J plates could be inspected, 14 were identified on these deep plates in addition to those identified on the Palomar Schmidt III a-J plates (a total identification percentage of 47). For 85 of the 238 radio sources in the 3rd Wbk sample (or 36%) an identification was found on the 127-04 and/or III a-J plates. Of the 155 BGS identifications, about 40% are with a stellar object, 45% with a galaxy and 15% with an object for which the type could not be determined. For the 85 identifications in the 3rd Wbk survey these numbers are 20, 55 and 25% respectively.

The criterion for identification was basically one of positional coincidence. From the position uncertainties and the density of objects on the respective plates/prints, we calculate that about 15% of the suggested identifications on Palomar Schmidt plates are spurious. For the identifications on the 4-m plates this fraction is slightly higher, 20–25%. Magnitudes were estimated for the identified objects that were visible on the Palomar Sky Survey prints by measuring image diameters. Magnitude–diameter relationships for galaxies and stellar objects were calibrated using the photoelectric data of Sandage[7,8]. These calibrations were done independently for the BGS sample (H.R. de R.) and the 3rd Wbk sample (P.K.). Magnitude estimates are probably correct to within 0.5–0.7 mag. As the BGS covers a large range in galactic latitude, a correction for galactic absorption was applied to m_b. This was not done for the 3rd Wbk identifications as these are all at fairly high galactic latitude. For identifications visible only on the Palomar Schmidt III a-J plates a blue magnitude was estimated, taking into account the estimated limit of about 22 mag (corrected for absorption).

Figure 1 shows a colour ($m_b - m_r$) versus magnitude (m_r) diagram for all galaxy identifications visible in the red Palomar Sky Survey prints ($m_r \leq 20$ mag) and for which a blue magnitude was available.

The most striking phenomenon in Fig. 1 is the presence of the very blue objects with $m_r \geq 19$ mag, occurring in both samples. In general, the agreement between the distributions of the BSG and 3rd Wbk samples is very good. We therefore conclude that there are no large systematic differences in the two sets of

magnitude estimates, although we cannot exclude the possibility that both data sets in Fig. 1 contain similar systematic errors. For instance, the very red colours of some galaxies with $m_r \sim 17$ mag are probably due to small (~0.5 mag) systematic errors in m_r. However, it is unlikely that the very blue colours of the galaxies with $m_r \geq 19$ mag are the result of systematic errors. Preliminary analysis of area photometry of some objects in the 3rd Wbk sample also indicates that there are no large systematic errors in the magnitude estimates of the faint galaxy identifications. We hope to obtain accurate photoelectrically calibrated photographic photometry for the objects in the 3rd Wbk sample.

Along the upper horizontal scale of Fig. 1 we have indicated the redshifts at which an elliptical galaxy with $M_r = -22.4$ would have the corresponding apparent magnitude (lower scale) in an $H_0 = 100$ kms s^{-1} Mpc^{-1}, $q_0 = 1$ geometry. The assumption of a constant M_r (independent of redshift) is not unreasonable because the red light is produced by a stellar population which evolves on very long time scales. We used the standard giant elliptical spectrum given by Pence[9] to calculate the red K-correction needed for this conversion. Figure 2 shows this red K-correction together with the blue K-correction calculated for the same spectrum. Figure 2 also contains the blue K-correction given by Code and Welch[10] on the basis of OAO UV-photometry of M87 (dotted line). These data do not seem to conflict with recent IUE spectral information on M87 (ref. 11).

Assuming an intrinsic colour $M_b - M_r = 1.9$ and using the K-corrections of Fig. 2, one predicts the colour–magnitude relationship shown in Fig. 1. Clearly the faint radio galaxies are very much bluer than expected. We may therefore question whether these objects are elliptical radio galaxies. Their classification as galaxy is reasonably certain because they all have extended (fuzzy) images. In principle, they could be subluminous and hence very nearby objects. However, this does not seem very likely since their angular sizes are what would be expected for galaxies at the redshifts that we have inferred. Therefore they are most likely to be elliptical galaxies, especially if one considers the observed ratio between optical and radio flux.

An interesting question is whether essentially all faint (m_r = 19–20 mag) radio galaxies are very blue, or rather: how many radio galaxies populate the inaccessible upper right-hand part of Fig. 1. This question cannot really be answered for the BGS sample, because this was defined on III a-J plates so that faint red galaxies are heavily selected against (if they exist). In the 3rd Wbk sample, which should be complete in m_r, there are two

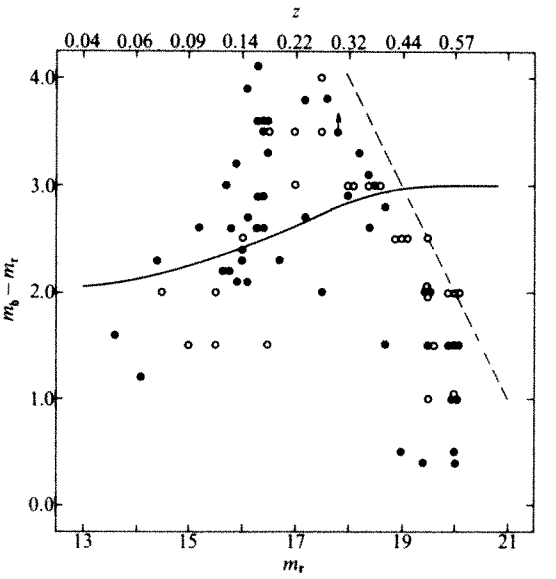

Fig. 1 Colour magnitude diagram of radio galaxies: ●, galaxies from BGS sample; ○, galaxies from 3rd Wbk sample. The solid line is the expected colour-magnitude relationship for a giant elliptical galaxy. The dashed line corresponds to $m_b = 22$ mag, the assumed limit of the III a-J plates.

objects (one galaxy and one object of uncertain type) in the range 19–20 mag that are not visible on the III a–J plate. Comparing this with the 12 objects in the same magnitude range below the $m_b = 22$ mag line, leads to the conclusion that most faint elliptical radio galaxies are much bluer than expected.

Our result only applies, of course, to radio-selected elliptical galaxies at redshifts of about 0.5. This 'colour evolution' may occur only in elliptical galaxies that contain a reasonably strong radio source. This would be consistent with the result of Kristian *et al.*[12], who find that the galaxies associated with the radio sources 3C299 and 3C330 (both brightest members of clusters at redshifts of about 0.5) are significantly bluer than the second brightest galaxy in the cluster. Undoubtedly, quite a few of the faint blue galaxies in Fig. 1 are also in clusters but with the present material we cannot tell whether the radio galaxies are bluer than other cluster members which presumably are even fainter. On the other hand, Butcher and Oemler[13] have obtained photometry of two distant clusters and find that the majority of the galaxies in these clusters are bluer than nearby early-type

Table 1 Magnitude–flux density tables for galaxies

galaxies. It is not clear whether this indicates that the mix of early- and late-type galaxies in these distant clusters is different from what it is in nearby clusters, or whether the early-type galaxies in the distant clusters are considerably bluer than the nearby ellipticals. Recent work by Kron[14] shows that the colour distribution of faint field galaxies widens strongly towards the blue at the faintest magnitudes. However, the effect seems to occur at least 2–3 mag below the level where we find the blue radio galaxies.

Redshift dependence of the RLF

Before discussing possible implications of these results we consider the other aspect of the identification statistics, which is the information they contain about the radio luminosity function of elliptical galaxies and its redshift dependence. The identification statistics are summarised in the magnitude–flux density tables shown in Table 1. These tables give the number of radio galaxies in various (Δm, $\Delta \log S$) intervals in three samples. In the case of the BGS samples (1) and (2) we used blue magnitudes, while the table for the 3rd Wbk sample (3) is based on red magnitudes.

Note here that Table 1 not only contains genuine galaxy identifications but also a fraction of the identifications with objects of uncertain type. These latter are generally faint identifications, most of which are expected to be galaxies, but which could not be convincingly classified as such from their appearance on the plate. On average, about two thirds of these objects are included in Table 1. In general their inclusion has a relatively small effect although in one or two bins it almost doubles the number of objects.

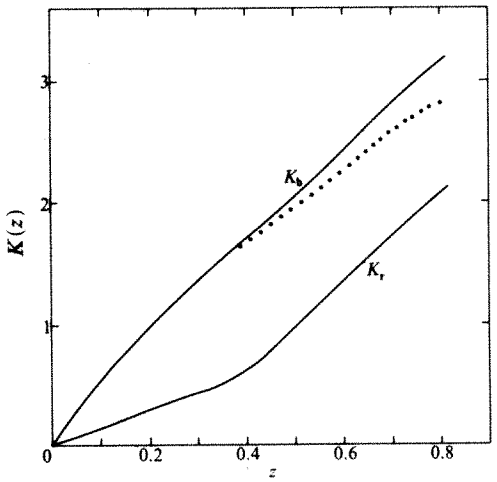

Fig. 2 Red and blue K-corrections based on Pence's standard energy distribution of giant ellipticals (solid lines). The dotted line represents the blue K-correction given by Code and Welch, based on the M87 spectrum.

Table 1 also shows in parentheses the number of radio galaxies expected in each bin if the local bivariate luminosity function of elliptical radio galaxies, as determined by Auriemma *et al.*[15], were valid at all redshifts. This bivariate luminosity function gives the space density of ellipticals as a function of radio luminosity P and absolute optical magnitude M. At any redshift the (Δm, $\Delta \log S$) interval transforms into a (ΔM, $\Delta \log P$)-interval, in which the number of objects per unit volume follows direction from the bivariate luminosity function. Integration over redshift and multiplication of the result by the solid angle covered by the survey in the $\Delta \log S$ interval yields the expected number of galaxies.

Table 1 shows that the observed and predicted numbers are in reasonable agreement for $m_b \leqslant 20.5$ and $m_r \leqslant 18.75$ mag. The average absolute magnitudes of the objects in question can be calculated from the local bivariate luminosity function[15] and are $M_b = -20.5$ and $M_r = -22.4$ mag for objects above the 'break' in the RLF. Using these values and the K-corrections of Fig. 2 the above apparent magnitude limits can be converted into redshift limits of ~ 0.3 and ~ 0.4 respectively. Only at fainter magnitudes (at higher redshifts) do the predictions fall short of the observed numbers, by an average factor of, say, 10 to 20.

The observations in Table 1 can be used to estimate the RLF if we ignore the dispersion in absolute magnitude at a given radio luminosity. Magnitude intervals can then be transformed into redshift intervals and, using the solid angles, into volumes, while flux densities transform into luminosities. The result of such a procedure is shown in Fig. 3 (the full curves shown represent our best estimate of the local RLF of elliptical galaxies, based on work by Colla *et al.*[16] and Meier *et al.*[17]).

Figure 3*b* and *c* give the RLF estimates obtained from samples (1), (2) and (3). The average uncertainty in a single point is shown by the 'error bars'. Estimates based on a single identification are enclosed in parentheses. Different magnitude intervals are indicated by different symbols and nominal average redshifts are given. It is again clear that for redshifts below say 0.3, our estimates do not differ significantly from our best estimate local RLF, which is based on ellipticals with redshifts of $\leqslant 0.1$. This conclusion extends a similar one by Meier *et al.*[17], who found no evidence for changes of the RLF out to redshifts of about 0.1. By a different, indirect method Robertson[18] also found little evidence for 'evolution' of the RLF below redshifts of ~ 0.2–0.3.

Both samples (1)+(2) and (3) show a strong increase of the space density in the high-redshift intervals. The results of the several samples are compared schematically in Fig. 3*d*. Although the three samples indicate the same general dependence of the RLF on redshift, sample (3) implies a much less drastic increase than do samples (1) and (2). We consider these differences significant and have investigated several possible explanations.

Colour and density evolution

Note that to first order an error in a zero-point of a magnitude scale displaces RLF estimates in a direction parallel to the local RLF, and hence cannot explain the differences in Fig. 3*d*. Different alinearities in blue and red magnitude scales could produce an effect like the one observed. For instance, assuming the results of samples (1) and (2) to be correct we find that the limits of the last m_r intervals should be about 19.3 and 20.1 mag, rather than the estimated 20.1 and 21.1 mag. Conversely, the difference in the limits of our III a-J plates from the 48-inch Schmidt and the 4-m telescopes would have to be >2.5 mag to produce consistency between samples (2) and (3). This is out of the question.

A more plausible explanation is, however, that the relationship between m_b and redshift is not what we assumed it to be on the basis of spectra of nearby ellipticals. In particular, if the UV spectra of the elliptical galaxies are more intense at higher redshifts, we would have underestimated their redshifts. In that case, the objects of sample (2) could be at redshifts of 0.7–0.8 rather than 0.5. This explanation produces consistency between the several RLF determinations and predicts a blue excess of the distant radio galaxies. The observed colour distributions discussed above and shown in Fig. 1 indeed show the faint radio galaxies to be markedly bluer than nearby ellipticals.

Note that the observed colours pertain to *bona fide* galaxy identifications, so that identifications of uncertain type are not represented in Fig. 1. The fact that a very small fraction of these galaxy identifications must be spurious does not change the result. Spurious identifications and identifications of uncertain type enter the determinations of the space density to some

The uncertainty in the indivdual estimates is shown by the 'error bars'. Nominal average redshifts have been indicated.

extent. The error bars in Fig. 3 include the uncertainties due to these effects, and we therefore think that the differences between the various determinations, which we interpret as evidence for blue colours of the very faint radio galaxies, are significant.

Obviously, the present data should be confirmed and improved. Better magnitudes and colours are required, as well as direct redshift determinations. Nevertheless, the data as they stand indicate that the last 25–30% of the lifetime of the Universe has been relatively quiet. The probability of an elliptical galaxy producing a radio source has decreased drastically. At the same time, the energy output in the UV may have decreased considerably. Of course, the two phenomena may be causally related. If the blue excess has a non-thermal origin, this relationship could be very direct; an active nucleus produces both a blue continuum and a strong radio source. If, on the other hand, the blue excess must be attributed to a very high star-formation rate this relationship would be less direct. In both cases an important question is whether the strong decrease of activity from the $z \sim 0.5$ to the present epoch is caused by evolution of individual galaxies, or is a manifestation of collective processes in clusters.

Solar luminosity and the sunspot cycle

R. H. Dicke
Joseph Henry Laboratories, Physics Department, Princeton University, Princeton, New Jersey 08544

Neither sunspots, flares, other solar activity, nor the solar wind, are found to be responsible for the 22-yr solar cycle period found in the [D/H] climate indicator. This period may be due to a periodic variation in solar luminosity induced by a deeply buried magnetic field.

THE discovery of the 11-yr periodicity in the abundance of sunspots by Schwabe[1] in 1843, had initiated the search for solar induced 11-yr periods in meteorological variables of various kinds, and by 1898 many solar–terrestrial relations had been claimed.[2] But many questionable conclusions had been based on inadequate statistics[3] and it was difficult to see how the weak effects expected from solar activity could significantly influence the weather.

Despite these difficulties, it was believed that there might be a connection between solar activity and the weather and the search for a solar–terrestrial relationship apparently led to the establishment of the Laboratory of Tree-Ring Research at Tucson in 1938. But it then took almost 40 yr of hard work to accumulate the tree-ring data which today represent a very substantial statistical base and yield a convincing indication of a drought cycle with a 22-yr period in the western US.[4] Although this 22-yr cycle had been indicated previously[5,6].

The tree-rings show, statistically, a drought cycle with a 22-yr period and not a 11-yr period. Indications of this 22-yr period, and/or the 11-yr period, have been found in several other variables: in the atmospheric pressure at high altitudes[7], in temperatures, rainfall and other phenomena[8–13], but these conclusions have not been uniformly accepted.

The statistically strongest indication of a sharply tuned 22-yr period in a climate indicator seems to be that found by Epstein and Yapp in the [D/H] isotope abundance ratios measured in the cellulose extracted from two bristle cone pine trees which together span 1,000 yr[14,15]. The period found is in excellent agreement with the double sunspot period[16]. The corresponding peak dominates the power spectrum and this peak has substantially the same breadth as that expected from a sinusoidal oscillation of 1,000 yr duration.

The signal strength, its spectral purity and its close agreement with the sunspot period indicate that these data are significant[16]. The suggestion that the 10-yr sampling period of [D/H] data could generate a false periodicity could only be true if successive samples were periodically treated differently in the analysis procedure and this seems unlikely. (Owing to the 10 yr averaging, these data could not provide information about the existence of an 11-yr period.) Assuming that the data are significant, the climate is presumably the source of the 22-yr period in the Epstein–Yapp data, but the details are unclear. Unfortunately, much more information would be needed to obtain a description of a 22-yr variation of the climate.

The advantage of the [D/H] ratio as a climate indicator may be the non-local measure of the climate which it provides. The [D/H] ratio in the precipitated water and incorporated into the plant cellulose depends on the mean surface temperature of the Pacific Ocean where the water evaporates and on the air temperatures where the various precipitations occur.

The 11-and 22-yr periodicities are not the only indications of a solar–terrestrial relationship in the weather. Several independent sources of data suggest that there may be a relationship between mildness of the climate and the average level of solar activity, for example, the sunspot number averaged over the 11-yr cycle. The more sunspots, the milder may be the climate[17–20].

Solar activity and the weather

All the obvious physical means by which the solar activity might influence the weather seem to be insignificant, and the presence of the 22-yr period makes the problem doubly difficult. As measured by number and distribution of sunspots the 11-yr period dominates the sunspot cycle. But when the magnetic polarities of the polar regions and the sunspots are included, the period is 22 yr. On symmetry grounds an alteration of the signs of all magnetic fields should not significantly affect energy balance and energy transport, hence the weather. But the polarity of the Earth's magnetic field does not reverse with the solar cycle and magnetic reversals on the Sun could induce a 22-yr period in the weather, but only if the Earth's magnetic field played a significant part (for example, by affecting the solar wind). The solar wind is estimated by Dessler[21] to carry energy to the Earth at a rate only 6×10^{-7} of the radiation flux from the Sun. This seems too small to be significant.

Other possible physical effects of solar activity seem to be equally weak. At sunspot maximum $\sim3\times10^{-4}$ of the Sun's surface is covered by sunspot umbrae, but a significant change in radiation flux is not implied. First the period is wrong, 11 yr rather than 22 yr, and second, there is not enough heat capacity in the upper part of the convective zone to store the excess heat if the solar radiation is throttled. To obtain an adequate thermal capacity requires a depth of 25,000 km where the pressure ($\sim5\times10^{10}$ dyn cm^{-2}) is $\sim10^5$ times as great as the typical sunspot magnetic pressure. Various effects of solar activity in the upper atmosphere have been reported, for example, on the vorticity[22,23].

Roberts says of the difficulty with solar–terrestrial relations in the weather, "It is hard to imagine a plausible scheme to have this tiny tail wag the huge dog"[6]. But does the "tail wag the dog"? It may be, as the various estimates suggest, that the sunspots, faculae, prominences, flares, solar-wind and all the other external manifestations of the solar cycle have a negligible effect on the weather and that the source of the 22-yr period seen in the [D/H] indicator is a solar luminosity variation generated deep inside the Sun. A significant correlation between A, the solar luminosity, and B, the solar activity, does not imply that B causes A, or vice-versa. Perhaps C causes both A and B. If so, what could C be?

The solar 'chronometer' and the luminosity

It has recently been shown[16] that there is no statistical support for the long-accepted 'eruption-hypothesis' as a description of the sunspot cycle. Under this hypothesis the sunspot cycle undergoes a large random walk in phase, but this random walk is not found statistically. Instead the sunspot cycle seems to be flexibly coupled to some internal 'chronometer', perhaps to a magnetofluid oscillator. The phase of the sunspot cycle correlates strongly with the peak sunspot number. The large phase

0028-0836/79/270024—04$01.00

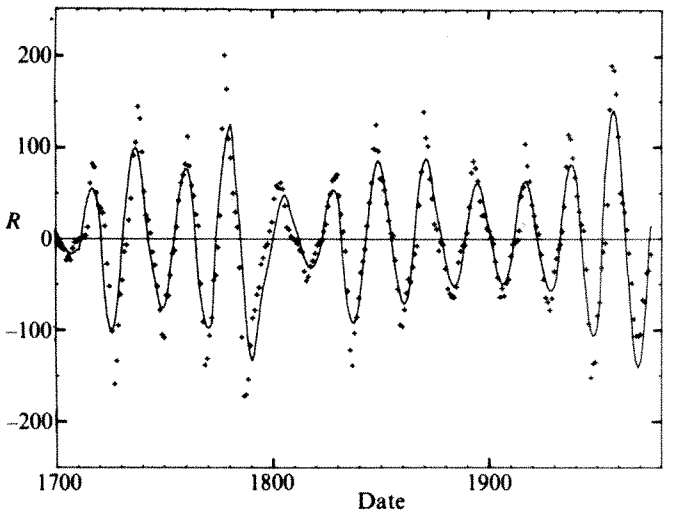

Fig. 1 Sunspot numbers of the (Hale) sunspot cycle and the fitted curve (equation (1)). (See test regarding sunspot numbers.) $\nu = 0.04489\ \mathrm{yr}^{-1}$; $\alpha = 0.015$; $c = 0.8708$.

fluctuation in the cycle may imply a long transit time for the magnetic field responsible for surface activity to float to the surface. If so, the correlation with the peak sunspot number implies that this transit time is less the more active the Sun.

The object C mentioned above might be the 'chronometer'. The Maxwell stress of the magnetic field could affect the energy transport to the surface and modulate the solar luminosity. (A reasonable site for this modulation is near the bottom of the convective zone.) The object C could also be the source of the magnetic field responsible for the sunspot cycle. If so, there are two expectations which might be tested statistically: (i) The solar luminosity should correlate with the sunspot cycle but with a phase delay in the sunspot cycle (the time required for the transport of magnetic flux to the surface). (ii) The correlation of the solar luminosity with the sunspot cycle should be better if the phase fluctuation in the latter is first removed. (The phase shift occurs after the modulation of the solar luminosity by the magnetic field.) These two expectations could be directly tested if one had a measure of the solar luminosity for the past 275 yr.

Solar luminosity, the [D/H] indicator and the sunspot cycle

If the above hypothesis is correct, the 22 yr periodic variation in solar luminosity may be the source of the 22 yr variation in the Epstein–Yapp [D/H] climate indicator[14]. This suggests that, as a working hypothesis, we tentatively interpret the indicator as a 'luminosity indicator' and investigate the correlation of the [D/H] data with the sunspot cycle.

As a first step, a curve is fitted to the yearly sunspot numbers[19,24] for the period 1700–1975 using the previously discussed[16] correlation of the phase of the solar cycle with the strength of the solar activity. According to Eddy[19] the sunspot curve, especially the absolute scale of the curve, is quite unreliable before 1817. Of particular concern is the possible systematic bias of early sunspot numbers through the loss of small sunspots due to poor seeing. From Kiepenheur's 'visibility function' for sunspots[25] an estimated correction factor of ~1.3 is obtained. This factor has been arbitrarily applied to all sunspot numbers before 1810. The correction is not secure and all calculations are also carried out with the correction factor omitted.

Figure 1 shows the yearly means of the sunspot number $R(t)$ for the period 1700–1975, with R plotted negative for alternate cycles starting with the first. The curve is a least square fit of

$$H = c\langle R\rangle \cos[2\pi\nu t + \delta_0 + \alpha\langle R\rangle] \qquad (1)$$

to the sunspot numbers $R(t)$ where

$$\langle R(t)\rangle = [(R^2(t-5) + \cdots R^2(t+5))/5.5]^{1/2} \qquad (2)$$

is an r.m.s. moving mean estimate of the peak sunspot activity. The phase shift $\alpha\langle R\rangle$ represents the previously found correlation of phase with the peak solar activity[16,26]. The parameters, c, ν, δ_0 and α are adjusted by least squares. The values obtained for ν and α are $0.044886 \pm 0.000054\ \mathrm{yr}^{-1}$, and 0.01153 ± 0.0083. The formally calculated error estimates are questionable as the residuals show evidence of unmodelled signal.

The double sunspot period p_s calculated from the above value of ν can be compared with the period previously obtained[16] from the Epstein–Yapp [D/H] data, p_D and with Wittman's[27] value, p_W, derived from a combination of telescopic data and a tabulation of naked-eye sunspot observations. These three values,

$$p_s = 22.279 \pm 0.027\ \mathrm{yr},\ p_D = 22.360 \pm 0.067\ \mathrm{yr},\ \text{and}\ \ p_W = 22.270 \pm 0.014\ \mathrm{yr} \qquad (3)$$

are all in satisfactory agreement. My attempt to obtain a sunspot period from the naked-eye sunspot data floundered in ambiguity[16].

The Epstein–Yapp[14] [D/H] weather indicator, D, is defined as the deviation, measured in parts per thousand, of the [D/H] abundance ratio from a standard oceanic sample. The 1,000 yr interval of time is covered by 100 10 yr samples yielding D_n, centred at t_n, where $n = 1 \ldots 100$. These data are filtered to remove low frequency noise by subtracting an approximately gaussian filtered moving mean to give the filtered data

$$D_n^\dagger = (-D_{n-1} + 2D_n - D_{n+1})/4 \qquad (4)$$

$D_n^\dagger$ is plotted in Fig. 2. The power spectra of both R and $D^\dagger$ (from Figs 1 and 2) are superimposed in Fig. 3 to show the coincidence of the strong 22-yr peaks.

If the fluctuations of the [D/H] ratio samples were induced by some solar function $f(t)$ lagged in time by τ yr, we would expect the decade time average of $f(t)$ defined by

$$f_n(\tau) = 0.1 \int_{t_n+\tau-5}^{t_n+\tau+5} f(t)\,\mathrm{d}t \qquad (5)$$

to correlate with D_n and the corresponding $f_n^\dagger(\tau)$ to correlate with $D_n^\dagger$. But then the least-square fit

$$c_0 + c_1 f_n^\dagger(\tau) \rightarrow D_n^\dagger \qquad (6)$$

to the N values of $D_n^\dagger$ could be used to determine c_0 and c_1 for a best fit to $D_n^\dagger$. The residuals are

$$\delta D_n^\dagger = D_n^\dagger - c_0 - c_1 f_n^\dagger(\tau) \qquad (7)$$

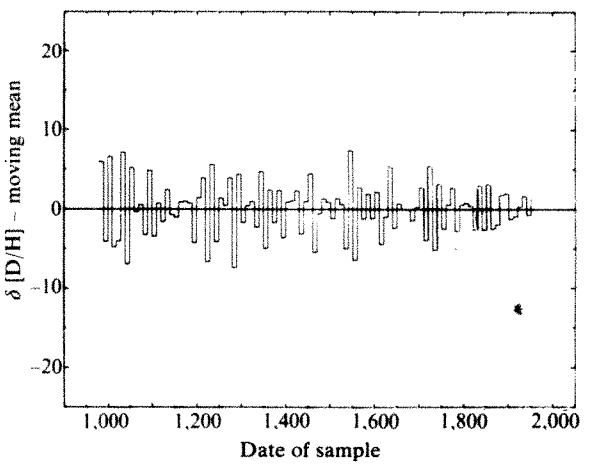

Fig. 2 The Epstein–Yapp Bristle Cone [D/H] data, $D^\dagger$ (filtered). $D_n^\dagger = D_n - 1/4(D_{n-1} + 2D_n + D_{n+1})$.

and the unbiased estimate of the residual variance

$$\sigma^2 = \sum_n (\delta D_n^+)^2/(N-2) \quad (8)$$

provides a measure of the goodness-of-fit, where $(N-2)$ is the number of degrees of freedom remaining after fitting c_0 and c_1. (The equivalent estimated unfiltered white noise variance is greater than in equation (8) by a factor of (8/3). The error of p_D, equation (3), has been corrected for filtering by the factor $(8/3)^{1/2}$.)

A 22-yr sinusoidal variation in solar luminosity might be expected to lead the 'luminosity indicator' D because of heat storage in the Earth. But from the discussion above, a much longer lag, not a lead, of the sunspot number R relative to D would be expected should the hypothetical internal modulation of the luminosity occur.

Adopting the sunspot number $R(t)$ as the function $f(t)$, equations (4)–(8) yield the unbiased estimate of the residual variance plotted as curve (1) of Fig. 4. The least-square fit equation (6) is calculated for the $N = 27$ values of D_n^+ covering the period 1665–1925. This residual variance can be compared with $\sigma_0^2 = 6.275$, the unbiased estimate of the variance of D_n^+ and equivalent to the residual variance obtained when the constraint $c_1 = 0$ is imposed on equation (6).

The above two-least square fits can be considered to represent alternative statistical hypotheses, (1) and (0) and the likelihood ratio of the two fits, with the fit under hypothesis (0) constrained by $c_1 = 0$, is

$$T = (L_0/L_1) = [\sigma^2(N-2)/\sigma_0^2(N-1)]^{N/2} \quad (9)$$

This ratio can be used to test the statistical significance of the various minima of the curves in Fig. 4 using Wilk's method. For large sample, $-2 \ln T$ has a χ^2 distribution with 1 d.f., assuming the truth of hypothesis (0). If a dip of a curve lies below the 1% level the prabability of the dip being a statistical fluke (hypothesis (0) being true) is 1% or less. All three dips of curve (1) are significant at the 1% level.

To see if the correlation is improved by eliminating the phase fluctuation from the sunspot cycle, the sunspot number R is replaced by the fitted function H (equation (1)) modified by replacing the phase term $\alpha\langle R\rangle$ by the constant $\alpha\langle\bar{R}\rangle$, where $\langle\bar{R}\rangle = 91.38$ is the mean value of $\langle R\rangle$ averaged over the period 1700–1975. With R replaced by H (modified), curve (2) is obtained. The two dips, occurring with lags of 2.5 and 13.5 yr, are statistically much stronger than those of curve (1).

The Maxwell stress of the magnetic field, not the field strength, should be responsible for the hypothetical modulation of the solar luminosity. To see if an amplitude modulation proportional to $\langle R\rangle^2$ yields an improved fit to D^+, the H (modified) used to generate curve (2) is further modified, replacing $\langle R\rangle$ by $\langle R\rangle^2$. The resulting curve (3) has dips at $\tau = 2$ and $\tau = 13$ yr which are slightly deeper than those of curve (2). At $\tau = 13$ yr the likelihood ratio between curves (2) and (3) is 17.2 (it is 2.67×10^3 for curves (1) (3)).

The locations of the minima and their depths, in curve (3), depend on two factors, the phase of the sunspot cycle and the amplitude $\langle R\rangle^2$ in H. To eliminate the phase of the sunspot cycle, f^+ in equation (6) is replaced by

$$\mathbf{H}_n^+ = [\langle R\rangle_{n-1} + 2\langle R\rangle_n + \langle R\rangle_{n+1}]^2 \cos[2\pi\nu t + \delta] \quad (10)$$

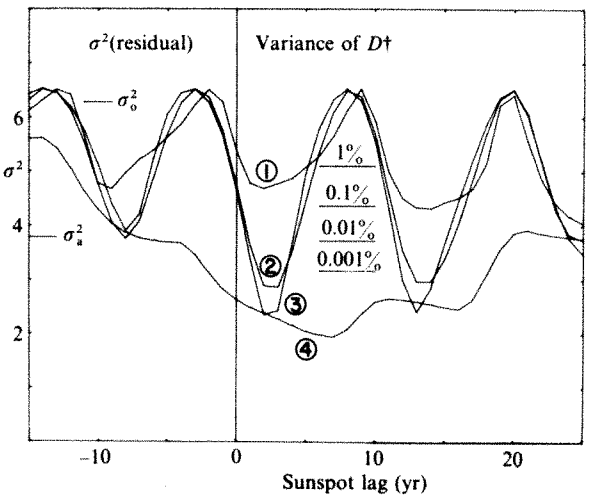

Fig. 4 The residual variance, equation (8), as a function of τ from the fit $c_0 + c_1 f^+ \rightarrow D^+$ with the following choices of f: ① $R(t)$; ② H (equation (1)) with the phase shift $\alpha\langle R\rangle \rightarrow \alpha\langle\bar{R}\rangle$ = constant; ③, same as ② but with amplitude $\langle R\rangle^2$; ④ f^+ from equation (10). The variance of D^+, σ_0^2, and the residual variance, σ_a^2, from equation (11) are also indicated.

with δ adjusted by least-squares. With f^+ replaced by $\mathbf{H}^+$, curve (4) is obtained. The locations of the minima of equations (2) and (3) are little influenced by the amplitude coefficient $\langle R\rangle^2$.

The strongest fit to the data D^+ is derived from equation (10) at the lag $\tau = 7$ yr (see Fig. 5).

Two peripheral questions remain: first, how good a fit to the data D^+ could be obtained by omitting the amplitude coefficient from $\mathbf{H}$ (equation (10))? The resulting function

$$f(t) = \cos[2\pi\nu + \delta] \quad (11)$$

gives a residual variance of $\sigma_a^2 = 3.785$, distinctly greater than the minima of curves (2) and (3) and less than the minimum of (1). Second, how do the above results differ if the bias correction of 1.3 is omitted? The sunspot period, to fit equation (1), is $p_s = 22.423 \pm 0.035$ yr^{-1}. It has a formal error 30% larger. It agrees with p_D but not with p_W (see equation (3)). Figure 4 is qualitatively unchanged. The dips in curve (1) are only a few per cent higher. The minimum of curve (4) is at $\tau = 6$ yr and is 43% higher. This dip is still significant, at a level of 10^{-5}. The conclusion reached is that eliminating the bias correction makes both the fit of equation (1) to the sunspot data and the fit of equation (6) to the D^+ data somewhat worse, but that, except for the 0.7% disagreement between p_s and p_W (a 4 σ discrepancy), the general conclusions reached in this paper are unaffected.

We return now to the expectations (i) and (ii). (i) Curve (1) of Fig. 4 shows a statistically significant correlation of 'luminosity' with R^+ lagged, assuming that D^+ is an indicator for a 22 yr periodicity in the luminosity of the Sun. (ii) Eliminating the variable phase of the sunspot cycle greatly improves the fit to the 'luminosity indicator' D^+. The phase lags (minimum σ^2) are substantially unaffected but the significance levels of the fits are very much better (0.001%) at the lags of $\tau = 2$ and 13 yr. The

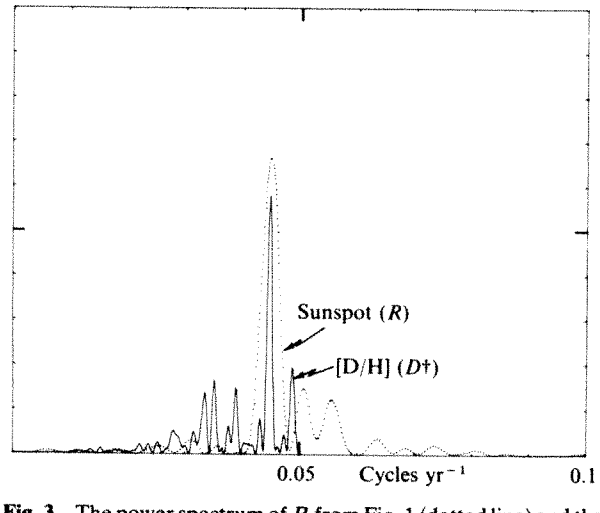

Fig. 3 The power spectrum of R from Fig. 1 (dotted line) and that of D^+ from Fig. 2 (solid line).

inclusion of the amplitude coefficient $\langle R\rangle$ (or $\langle R\rangle^2$) gives a distinctly better fit than is obtained assuming a simple periodic function for $f(t)$.

The phase fluctuation in R is not detectable (at a 2 σ level) in D^+. This is shown by simultaneously fitting H^+ from equation (1) and H^+ modified to eliminate the phase fluctuation to D^+. The regression coefficients are respectively 0.007 ± 0.029 and 0.032 ± 0.008. (The errors are corrected by the factor $(8/3)^{1/2}$ for noise filtering.) The first term is not present in D^+ to a measurable extent.

The two lags, $\tau = 2$ and 13 yr of curves (2) and (3) are equally strong statistically but a delay of 2–3 yr, for the eruption of magnetic field at the solar surface, after the modulation of the luminosity is inadequate to permit the large variation in phase seen in the sunspot cycle. This suggests that ~13 yr is required for the magnetic field to float to the surface.

Discussion

The 22.36 yr period in the [D/H] climate indicator (D) could be a statistical fluke. But if the 22.36 yr periodicity is meaningful, its close correspondence with the period of the sunspot cycle (Fig. 3), strongly suggests a causal relationship with the solar cycle.

If the solar cycle is driving this periodicity in D, neither sunspots, faculae, flares, other solar activity, nor the solar wind can be responsible. Because all of these surface phenomena exhibit the large phase fluctuation discussed above whereas it has been shown that this phase fluctuation is not present (at a 1 σ significance level) in D.

If this 22 yr period in D is meaningful, is due to the Sun, and is not due to any surface or external activity of the Sun, what induces it? A periodicity varying luminosity is a feasible source of variation in the climate, but then the variation must be induced in the deep interior of the Sun, probably towards the bottom of the convective zone and probably by magnetic fields. The work of Epstein and Yapp[14,15,28] has established that D is sensitive to variations in the climate.

We have shown that the Epstein–Yapp indicator D^+ and the sunspot numbers R are consistent with the following assumptions: (1) that the filtered [D/H] data, D^+, monitors a 22-yr luminosity variation of the Sun; (2) that the luminosity is modulated by a deeply buried magneto-fluid dynamic oscillator associated with a 'solar chronometer'[16]; (3) that some part of this magnetic field floats slowly to the surface where, years later, it is responsible for 'solar activity'; and (4) that the magnetic field arrives at the surface approximately

$$13 - \left(\frac{\alpha}{2\pi\nu}\right)(\langle R\rangle - \overline{\langle R\rangle}) = 13 - 0.041\,(\langle R\rangle - 91.4)\ \text{yr} \quad (12)$$

after the modulation of the luminosity, where $\langle R\rangle$ is evaluated at the time of arrival at the surface. The hypothetical luminosity modulation is found to have the phase stability of the 'solar chronometer'[16].

The amplitude of the 22-yr period in D^+ (based on all the data and after correcting for the effect of 10-yr averaging) is 3.8 ± 0.5 (see Table 2 of ref. 16). A crudely estimated temperature equivalent of a variation in D ($\delta T/\delta D \cong -0.2°$) is obtained from a comparison of modern values of D and T with those found in North America at the time of the late Wisconsin glacial maximum[28,29]. Owing to the long time scale of the Wisconsin glaciation and the large magnitude of the variation δD, even the sign of $\delta T/\delta D$ is uncertain when applied to the 22-yr cycle. Nonetheless, the implied times of temperature maximum 1891.0, 1913.3, 1935.7 and 1958.0 (Table 2 of ref. 16) are found to be in rough agreement with the dates of the highplains droughts, 1890, 1913, 1934 and 1954[6].

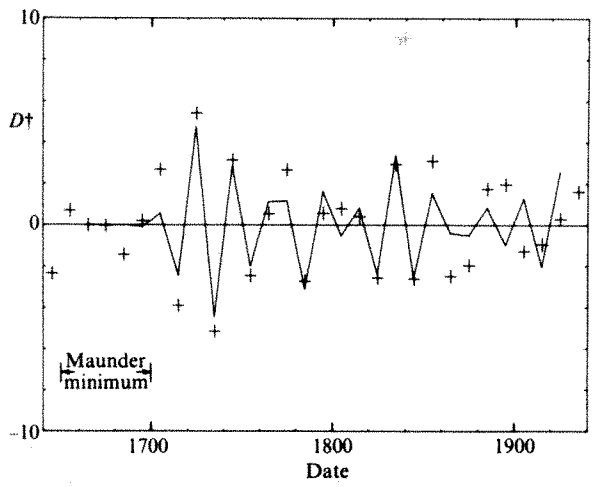

Fig. 5 The fitted function $c_0 + c_1 \mathbf{H}^+$, equation (10), and the data points D^+ where c_0, c_1 and δ are determined for $\tau = 7$ yr. $\nu = 0.04489\ \text{yr}^{-1}$.

For a black-body response of the Earth this estimated temperature amplitude of 0.8 °C corresponds to a 1.1% (amplitude) variation of the solar luminosity. More realistic calculations, including albedo feedback effects yield 0.55%, 0.7% and 0.18% for calculations by Budyko, Manabe and Welterald and Schneider and Gal-Chen respectively[30].

The only long series of observations of the solar constant, that of Abbot, shows a questionable ~23-yr period[31]. A 0.13% amplitude and a maximum at 1937 are obtained from a fit of a 22.3 yr period to the 1926–46 Abbot data. More recently, balloon flight measurements have given a luminosity increase from 1968 to 1978 of 0.4%, corresponding to an amplitude of the 22-yr period of 0.24%[32], assuming the correctness of the D^+ phase.

$^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ ratios from the Azores and their significance in LIL-element enriched mantle

C. J. Hawkesworth*, M. J. Norry†, J. C. Roddick & R. Vollmer‡

Department of Earth Sciences, University of Leeds, Leeds, UK

Basalts from Sao Miguel are displaced to higher $^{87}Sr/^{86}Sr$ ratios, and have a significantly shallower slope, compared with the main correlation between $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ for most mantle-derived volcanic rocks. Available data on young magmatic rocks indicate that large ionic lithophile (LIL)-element enrichment in the upper mantle involves two readily distinguishable components which reflect different histories.

MOST oceanic volcanic rocks have higher $^{143}Nd/^{144}Nd$ and lower $^{87}Sr/^{86}Sr$ ratios than the present-day composition for the model bulk Earth[1]. This implies that the oceanic upper mantle has been depleted in Rb and light rare earth elements (LREE) for much of its history. However, there are areas in the ocean basins where volcanic rocks are clearly not derived from a LIL-element depleted source. These are characterised by high concentrations of LIL-elements, high Rb/Sr, Rb/K and Ce/Yb ratios relative to most oceanic lavas, and are referred to as mantle 'hot spots' or 'plumes'[2,3]. $^{143}Nd/^{144}Nd$, $^{87}Sr/^{86}Sr$, and REE analyses from one such 'hot spot', the Azores (38° N 25° W), are compared with those from other LIL-element enriched areas. Constraints on models for the nature and timing of enrichment-depletion events in the upper mantle are then discussed.

Sample analyses

The samples analysed are all from the island of Sao Miguel (Fig. 1). This is the largest of the islands in the Azores and it was selected because it has been the subject of extremely detailed geological[4] and petrochemical work (ref. 5 and Marriner, Norry and Gibson, unpublished data). Its lavas are richer in LIL-elements than those from the other islands of the Azores at the same degree of fractionation; and they were also known to exhibit a larger range in $^{87}Sr/^{86}Sr$ (0.7035–0.7052) (ref. 6).

Eleven samples (Table 1), all alkali basalts, were chosen from the collections made by Gibson and Walker. They are from the stratovolcanoes of Aqua de Pau and Sete Cidades and the fissure eruptions between them, and are associated with large volumes of trachyte and hawaiite. The lavas used in this study contain more than 5% MgO and have olivine, clinopyroxene, and sometimes plagioclase, phenocrysts. K_2O ranges from 1.5 to 2.6% and like the other incompatible elements, its concentration is not a simple function of fractionation.

$^{87}Sr/^{86}Sr$ and $^{143}Nd/^{144}Nd$ were analysed by techniques reported previously[7] and range from 0.7032 to 0.7052 and from

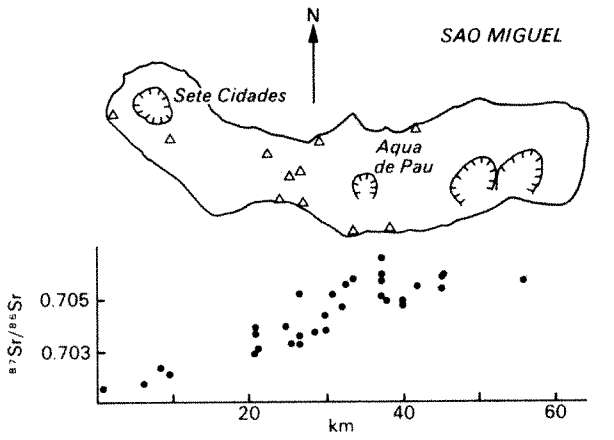

Fig. 1 Sketch map of Sao Miguel in the Azores illustrating the localities of the samples analysed in this study, and the marked increase in $^{87}Sr/^{86}Sr$ ratios from west to east across the island. Data from this work, Marriner, Norry and Gibson (unpublished), and ref. 6.

0.51300 to 0.51276 respectively (Table 1). They exhibit an inverse correlation between $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ but have a slope which is much shallower than that observed in lavas from MOR and islands such as Iceland, Bouvet, and Tristan da Cunha[8] (Fig. 2). They might, therefore, reflect high level contamination[9] by either seawater or oceanic sediments but for the following reasons we find such an explanation unconvincing.

(1) All the samples were collected from subaerial flows which have not been in contact with seawater. Thus any interaction with seawater (or sediments) presumably takes place within the magma chamber(s).

(2) Assuming that ocean water has $^{87}Sr/^{86}Sr = 0.7092$, $^{143}Nd/^{144}Nd = 0.5124$ (ref. 10 and Hawkesworth and Elderfield,

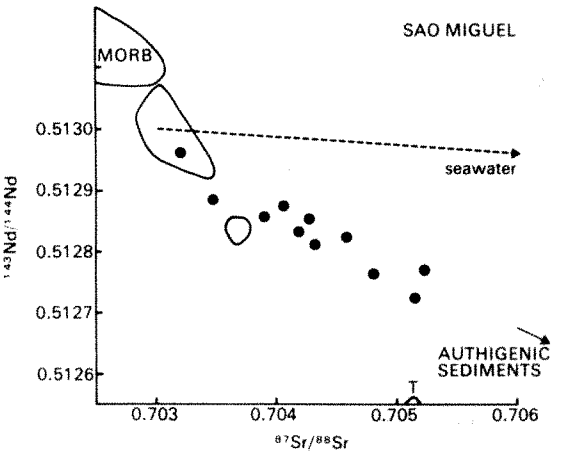

Fig. 2 $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$ for basalts from Sao Miguel. I, Iceland; B, Bouvet; T, Tristan da Cunha[8]. BCR $^{143}Nd/^{144}Nd = 0.51262$, E–A, $^{87}Sr/^{86}Sr = 0.70800$.

unpublished data), and Sr/Nd = 10^6 (ref. 11), then mixing it[12] with magma of composition 0.705 and 0.5130 results in the almost horizontal trend shown on Fig. 2. This does not seem to be responsible for the slope of the Sao Miguel data.

(3) Given an average of 725 p.p.m. Sr in the basalts and 8 p.p.m. in ocean water, very large water/rock ratios (perhaps 30–50) are implied if the compositions of the basalts are controlled by seawater interaction. Moreover, in contrast to the MOR environment this large volume of water would have to be heated to magmatic temperatures.

(4) Sao Miguel rises some 3,000 m above the floor of the mid-Atlantic Ocean. Moreover, a 1 km drill hole into pillow lavas on the island did not encounter any sediments. Thus for sedimentary material to act as the contaminant it must be dragged down into the magma chamber (presumably along the transform feature), heated to magmatic temperatures, and then mixed in without affecting the primitive nature of the basalts.

It is apparently difficult to attribute the correlation between Nd and Sr isotopes in the Sao Miguel lavas to high level contamination by seawater or oceanic sediments. We believe, therefore, that their isotope geochemistry reflects processes operating within the upper mantle.

There is no simple relationship between the trace element and isotope geochemistry of the lavas studied from Sao Miguel. Eight REE have been determined on each sample using standard isotope dilution techniques[13] (Table 2). They are all highly enriched in LREEs ($Ce_N/Yb_N = 14.2–10.0$) and only three samples contain detectable Eu anomalies which presumably reflect minor accumulation/fractionation of plagioclase phenocrysts. Considering only the samples without Eu anomalies their Rb/Sr ratios fall in the narrow range of 0.053–0.061 while $^{87}Sr/^{86}Sr$ varies from 0.7032 to 0.7048. Similarly $^{143}Nd/^{144}Nd = 0.51300–0.51276$, but Sm/Nd only varies from 0.19 to 0.21. Thus, although we emphasise that there is no clear relationship between isotope composition and trace element ratios, the narrow range of the latter means that they would take 3,000–5,000 Myr to generate the observed range in Nd and Sr isotopes. This is clearly unlikely, and the variation in $^{143}Nd/^{144}Nd$ and $^{87}Sr/^{86}Sr$ in the Sao Miguel basalts, therefore, probably reflects some recent mixing process.

Further support for this conclusion may be found in the striking regional variation in $^{87}Sr/^{86}Sr$ ratios across the island (Fig. 1). It suggests that mixing of magmas or sources took place beneath Sao Miguel and that the high $^{87}Sr/^{86}Sr$ component becomes increasingly important in the centre and east of the island. The low $^{87}Sr/^{86}Sr$ component has Nd and Sr isotope ratios which lie on the main trend of the Atlantic Ocean volcanic rocks (Fig. 2).

Discussion

Combined Nd and Sr studies have shown that lavas from LIL-element enriched source regions often have isotope compositions which indicate that these sources have actually been depleted in LIL elements for much of their history. Thus when discussing the trace element characteristics of a portion of the upper mantle a clear distinction must be made between those deduced from trace element chemistry in basalts and those inferred from isotope composition.

The isotope results presently available suggest that LIL-element enriched volcanic rocks may usefully be divided into two groups (Fig. 3). Group I consists of the main trend of volcanic rocks on which estimates of the present day $^{87}Sr/^{86}Sr$ ratio of the bulk Earth rocks are based[1]. It is characterised by a steep slope on $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$ and notably, most of

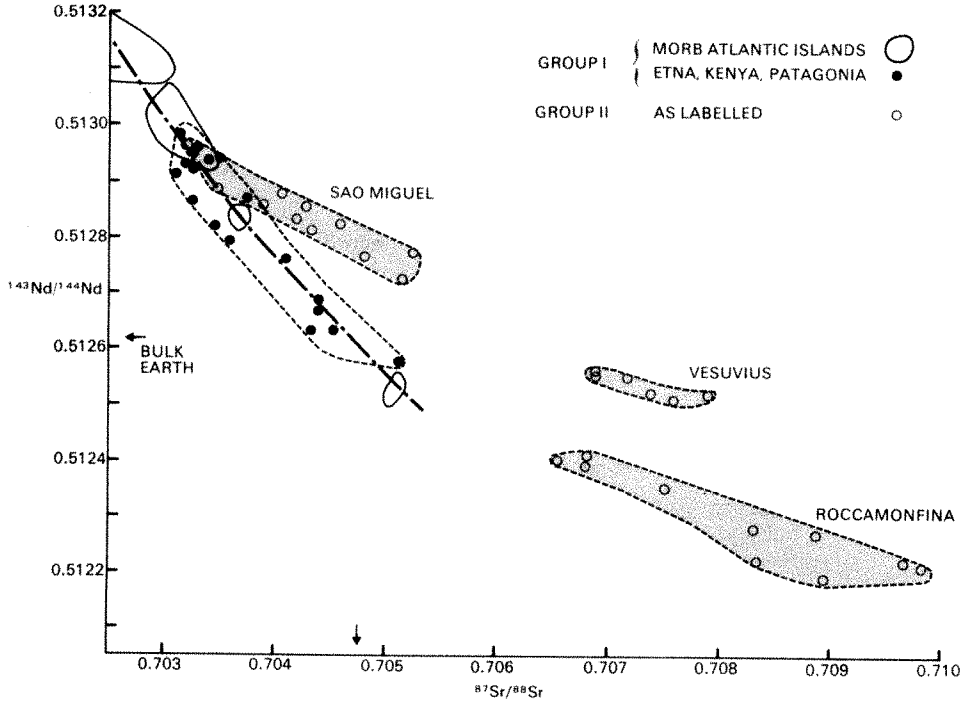

Fig. 3 $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$ for basalts from oceanic and continental environments. MORB and Atlantic Islands as in Fig. 2. Results from refs 7, 8, 14, 21, 24 and this work. Present day bulk Earth composition after De Paolo and Wasserburg[15] and O'Nions *et al.*[8].

the volcanic rocks from both oceanic and continental environments have present Nd and Sr compositions indicative of LIL-element depletion (relative to the model bulk Earth) for long periods of time.

Group II (Fig. 3) is distinguished because its lavas fall on trends of significantly flatter slope which plot to the right of the main trend of oceanic and continental volcanics (group I) on the $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$ diagram. Hence they might all reflect contamination; by seawater, sediments, or continental crust. Reasons for rejecting such a hypothesis for Sao Miguel have been outlined above. Hawkesworth and Vollmer[14] argued for Roccamonfina that the positive correlation between $^{87}Sr/^{86}Sr$ (0.7064–0.7096) and Sr content (800–2,000 p.p.m.) in its primitive lavas is most unlikely to have been generated, or affected significantly, by interaction with continental crust. There are much less data from Vesuvius[14] but by analogy with Roccamonfina the geochemistry of its lavas are also thought to have been largely unaffected by crustal contamination. Thus we believe that the flat-lying trends of the group II lavas do not reflect contamination but reflect processes active within the upper mantle.

The variation of the trace element ratios relevant to Nd and Sr isotopes can be simply represented on a diagram of Sm/Nd versus Rb/Sr (Fig. 4). Note that the broad curve of the data does not include the point for the Rb/Sr and Sm/Nd ratios of the bulk Earth deduced from Nd and Sr isotope studies[1,8,15]; as might have been expected if the mantle had a simple history of depletion or enrichment.

Also shown on Fig. 4 are the results of batch melting calculations on garnet lherzolite which have been outlined in more detail elsewhere[16]. They illustrate that for amounts of melting exceeding 5–10%, little displacement occurs between melts and their source rocks when plotted on Fig. 4, and that source rocks in quadrant 2 have had a multi-stage history. The simplest model necessitates depletion of a portion of the mantle by extraction of at least 0.5% of liquid followed by remelting to form a second liquid which could mix with other depleted portions of the mantle[16] (Fig. 4).

The Nd and Sr isotope results also suggest that the source regions of the group I lavas have had a complex history. Hawkesworth *et al.*[16] pointed out that the isotope variations on the main trend of the group I lavas could not be reproduced by two-stage models (see Fig. 5) and concluded that some large-scale mixing process was responsible. O'Nions *et al.*[17] suggested that the main Nd and Sr isotope correlation (group I, Fig. 3) results from fractionation of the crust from the mantle throughout geological time, accompanied by continuous remixing of the mantle reservoir. Such a process, while explaining the remarkably good Nd and Sr isotope correlation observed from a large number of areas (group I, Fig. 3) would imply that most mantle materials should have lower Rb/Sr and higher Sm/Nd ratios than the bulk Earth (see quadrant 1, Fig. 4). This is true for MOR lavas and tholeiites from Iceland but many oceanic island and continental basic lavas do not have these characteristics and plot instead in quadrants 2 or 3 of Fig. 4.

Provided that these lavas are produced by amounts of melting exceeding a few per cent, and have not been subject to large amounts of plagioclase fractionation, their source regions will also plot within these quadrants. Prolonged residence in quadrant 2 will result in Nd and Sr isotope compositions plotting to the left of the main isotope correlation (Fig. 3). Lavas with such compositions are rare and when observed in the British Tertiary Province they have been attributed to assimilation of Rb-poor granulite facies crustal material[18]. In general, however, most lavas in quadrant 2 of Fig. 4 plot on the main (group I) trend of Nd and Sr isotopes (Fig. 3). Thus we conclude that the enrichment of LIL-elements in their source regions must have taken place comparatively recently so that insufficient time has elapsed to affect their isotope ratios significantly.

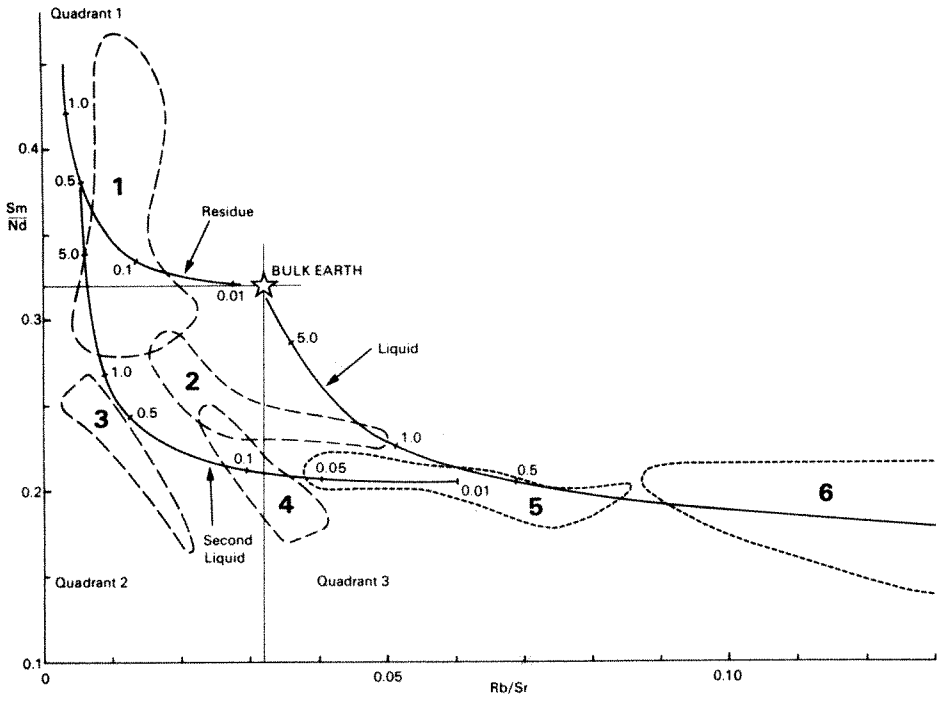

Fig. 4 Plot of Sm/Nd versus Rb/Sr in the more primitive rock types from Iceland (1), Hawaii (2), Etna (3), Patagonia (4), (all group I), and Sao Miguel (5) and Roccamonfina (6) (group II—see Fig. 3). Data from refs 7, 8, 14, 24, 25 and this work. The results of batch melting calculations are from ref. 16 and have the melt fractions in per cent.

Quadrant 3 (Fig. 4) contains lavas derived from source regions with high Rb/Sr and low Sm/Nd ratios; they would develop with sufficient time a flat-lying trend plotting to the right (that is, high $^{87}Sr/^{86}Sr$) of the main (group I) trend on the diagram of $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$.

The group II lavas plot in Fig. 4 quadrant 3 and have the flat-lying trend between Nd- and Sr-isotopes that is predicted for source regions which have had variable but high Rb/Sr and low Sm/Nd ratios for a significant period of time. Assuming that trace element ratios in the source region can be estimated from those in the lavas, these would seem to be the ideal situations for recognising 'mantle isochrons'[19] which might 'date' old enrichment events in the upper mantle. However, where such lavas have been analysed for more than one isotope system, the simplest interpretation of the data seems to be that they also reflect geologically recent LIL-element enrichment. At Roccamonfina, for example, the primitive rock types exhibit positive correlations between $^{87}Sr/^{86}Sr$ and Rb/Sr, and $^{143}Nd/^{144}Nd$ and Sm/Nd, but the calculated ages are 500 and 2,000 Myr respectively[14]. Since the $^{207}Pb/^{204}Pb$–$^{206}Pb/^{204}Pb$ results correspond to an age of almost 0 Myr (ref. 20) we conclude that these 'mantle correlations' are most unlikely to have any real age significance and probably reflect a recent mixing/enrichment event within the upper mantle.

More speculatively it has been suggested that the Nd and Sr isotope compositions from Sao Miguel also reflect some recent mixing process. The high $^{87}Sr/^{86}Sr$ component in both examples presumably evolved by virtue of its source having had the high Rb/Sr and low Sm/Nd ratios characteristic of quadrant 3 (Fig. 4) for a significant period of time. It is envisaged that at Sao Miguel this component mixed with material that had LIL-element depleted isotope characteristics similar to Iceland, while at Roccamonfina it mixed with material similar in composition to the model bulk Earth (Fig. 3).

Conclusions

The available Nd and Sr isotope results on recent oceanic and continental volcanics may be conveniently considered in two groups (Fig. 3). Group I includes most of the available oceanic data and is therefore much more significant in terms of volume of mantle sampled. It forms a steep, negative correlation on a graph of $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$, and most of the isotope compositions indicate derivation from source regions which have been depleted in LIL elements relative to the bulk Earth for a considerable time. Recent LIL-element enrichment events are recognised in both oceanic and continental areas, and it is noticeable that (1) the LIL elements have migrated from source regions which also have Nd and Sr isotopes on the trend of the group I samples and (2) that although Rb and Sr abundances are increased during LIL-element enrichment, the Rb/Sr ratios rarely exceed 0.04 (Fig. 4).

Group II samples, in contrast, have shallower slopes and plot to the right of the main correlation (group I) on the graph of $^{143}Nd/^{144}Nd$ versus $^{87}Sr/^{86}Sr$. Volumetrically they are clearly much less significant, but an example is now available from both the oceanic and continental environment and their significance lies in the fact that they clearly involve a different component to those in group I (Fig. 3). We have argued that in the cases studied, this component is most unlikely to be introduced by contamination during magma extraction and that it is therefore present in the upper mantle. It results in high Rb/Sr ratios (>0.04) and correspondingly high $^{87}Sr/^{86}Sr$ ratios relative to $^{143}Nd/^{144}Nd$. Moreover, since these are often taken to be crustal characteristics, one possible explanation is that this group II component might reflect subducted crustal material which has retained its identity in the upper mantle (O'Nions *et al.* unpublished).

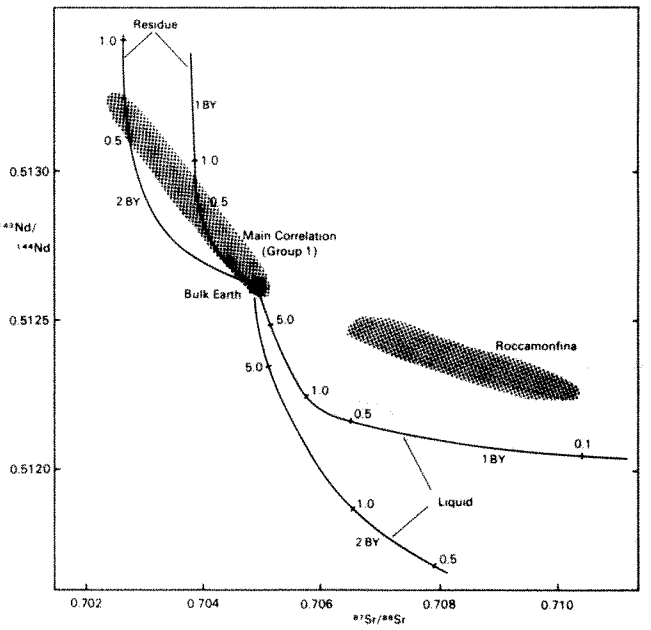

Fig. 5 Nd- and Sr-isotope evolution for two-stage models in which melting occurred 1,000 and 2,000 Myr ago[16]. Melt proportions in per cent.

Alternatively mantle metasomatism, as documented from mantle xenoliths in kimberlite by Erlank and coworkers[22,23], can result in LIL-element enrichment which will with time generate the relatively high $^{87}Sr/^{86}Sr$ and low $^{143}Nd/^{144}Nd$ ratios apparently characteristic of the group II end members. It is difficult to determine how long such material needs to be isolated, but note that the data from nodules of metasomatised mantle indicate that $^{87}Sr/^{86}Sr$ ratios of 0.705–0.710 can be generated in only 150 Myr (ref. 23).

We thank J. Kramers and R. K. O'Nions for helpful comments. Isotope research at Leeds is supported by grants from NERC and the Royal Society, and we acknowledge NERC Fellowships during this work. We thank M. Greaves, P. Guise, and A. Gledhill for technical assistance.

An exceptional intraplate earthquake sequence in Meløy, Northern Norway

H. Bungum, B. K. Hokland, E. S. Husebye & F. Ringdal
NTNF/NORSAR, PO Box 51, N-2007 Kjeller, Norway

A unique earthquake sequence began in Meløy, Northern Norway, in November 1978, and 10 weeks later about 10,000 shocks had been recorded from a volume not larger than $10 \times 8 \times 6$ km^3. The largest earthquake occurred on 28 November, 1978, with an ML magnitude of 3.2 and a maximum MM intensity of VI.

ALTHOUGH Norway is far away from plate boundaries—the nearest ones being the Mohn's and Knipovich Ridges in the Norwegian Sea—the region exhibits a relatively high seismic activity in the context of intraplate earthquake occurrence. Husebye *et al.*[1-2] have scrutinised all available evidence on the seismicity of this region, including historical records of 400 yr ago. The largest occurring earthquakes were found to have had magnitudes of the order of 6.0–6.5, and broad seismic zones could be delineated, usually in agreement with major tectonic features. In November 1978 a remarkable earthquake sequence began in Northern Norway, where about 10,000 shocks were recorded during the first 10 weeks of instrumental coverage. This unique phenomenon, which is still taking place at a reduced rate is described here.

Background and instrumentation

It is uncertain when the Meløy earthquake sequence started, but the first earthquake positively recorded at NORSAR (the Norwegian Seismic Array, almost 700 km away) occurred on 3 November 1978 and was measured at $ML = 2.4$. *ML* is the local magnitude calculated from the Sg phase and based on wave attenuation characteristics representative for Scandinavia[3]. Between 12 and 19 November, ground shakings were often felt, particularly at night time, and some cracks in chimneys and walls were observed. The shocks were accompanied by relatively strong bangs and rumblings. On 16 November NTNF/NORSAR were asked to monitor the area, and two days later the first seismographs (type Sprengnether MEQ-800) were installed. A maximum of five stations were in operation at one time while seven different sites were used (for details, see Fig. 1 and Table 1). Three of these sites—ENG (Enga), NEV (Neverdal) and ORN (Ørnes)—were chosen as permanent locations. Figure 2 shows the microearthquake activity on one of the most active days. Accelerometers, hydrophones and analog and digital tape recording of three-component seismometers were also installed on an experimental basis and operated for short time intervals. (Field work in the rugged Meløy area is very difficult in winter so more extensive monitoring experiments are planned for the summer assuming the earthquake sequence continues until then.) Besides the NORSAR array, several other seismograph installations in Scandinavia have recorded the largest Meløy earthquakes. Whenever possible, the NORSAR recordings have been used to measure the local *ML* magnitude.

Earthquake sequence in time and space

Minor tremors are not uncommon in the Meløy area, and the first reported rumblings that may be associated with the present sequence date back to around 20 October 1978. While it is difficult to determine the exact starting date, it seems that the main activity started around 10 November 1978.

The timing of the earthquake sequence between 11 November 1978 and 26 January 1979 is given in Fig. 3 for station NEV and shows the total number of events per 4-hourly time interval, the cumulative number of events (ending at about 7,500), and all events with an *ML* magnitude of at least 2.0. The main concentration of larger shocks was between 11 and 18 November, and there is also an interesting predominance of night-time shocks during this interval. The activity was high and fairly constant (although with large short-term variations) up to 5 December, then decreased to a minimum around 20 December, whereafter new outbursts of activity occurred on 27–28 December, 3–4, 8–10 and 18–20 January. Comparing the occurrence of the larger events with the total activity we see a repeated pattern of 'main' shocks followed by aftershocks lasting sometimes a few hours, sometimes a few days.

A detailed study of the sequence shows only one example of foreshock activity: the $ML = 2.9$ event on 27 December which was preceded by nine small shocks starting 90 s before the main one. Apart from that event, the main shocks were always preceded by a period of relative quiescence. There are also examples of large sub-sequences not preceded by a main shock,

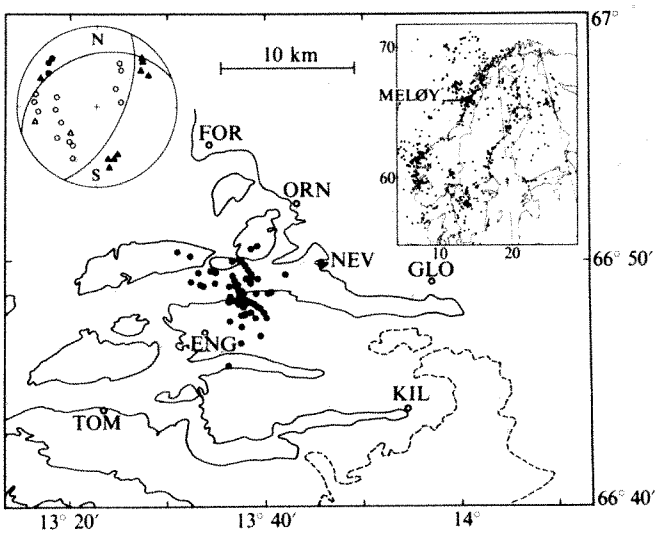

Fig. 1 Map of the Meløy area with the locations of seven seismic stations whose times of operation are given in Table 1. The dotted line to the south-east indicates a glacier (the whole area is very mountainous). ●, Computed epicentres for 66 earthquakes for which from 5 to 10 readings (phases) were available (see text for details) and the corresponding depth range is 3–9 km. The upper right insert shows Fennoscandia with instrumentally located earthquakes for the time period 1951–78, and the location of Meløy is also given. The upper left insert is a composite focal mechanism solution for the Meløy earthquakes, where compressions (solid symbols) and dilatations (open symbols) are plotted in a lower hemisphere stereographic projection. See text for explanation of symbols. The two nodal planes have strikes/dips of 25°/63° E and 250°/35° N, respectively.

Table 1 The Meløy microearthquake stations with recording time intervals and the respective numbers of recorded events

Station	Code	Start	Stop	Recorded events
Fore	FOR	18.11.78	22.11.78	95
Neverdal	NEV	18.11.78	26.01.79*	7,494
Tømmervik	TOM	19.11.78	23.11.78	34
Kilvik	KIL	21.11.78	27.11.78	175
Enga	ENG	23.11.78	26.01.79*	7,628
Glomfjord	GLO	24.11.78	29.11.78	41
Ørnes	ORN	26.11.78	26.01.79*	2,970

* Station still in operation, March 1979.
The total number of individual events recorded up to 26 January 1979 was 9,954. See Fig. 1 for station locations.

such as on 4 January when 103 microearthquakes were recorded at ENG within an hour with no event magnitude exceeding $ML = 2.0$. The largest number of events recorded in one single day occurred on 2 December with 820 at ENG, 750 at NEV and 270 at ORN.

The hypocentre was located as follows: an initial epicentre estimate was obtained on the basis of S–P time differences using a maximum likelihood technique[4,5] and then refining this estimate iteratively using absolute P/S arrival times when such data were available. The associated crustal model was the simplest possible, with a P_g velocity of 6.25 km s^{-1} (P_b or P_n were never observed), and a P/S velocity ratio of 1.78. Depth of focus was obtained by looping over a specified number of depths, choosing the one which resulted in the smallest time r.m.s. value. This procedure has proved to be reliable even with unfavourable conditions such as non-symmetric station configuration, few observations and unreliable station timing corrections.

We have computed hypocentres for 255 events evenly distributed in time throughout the recording period. These were all intermediate magnitude events, as the largest ones could not be read reliably because of large deflections (saturations) on the paper recordings. Between three and five stations and between six and 10 phases (S–P relative time counts as one phase) have been used. Out of 87 hypocentral solutions with five or more phases, 85% have r.m.s. values <0.20 s and 45% have r.m.s. values <0.10 s. For the same events the largest semi-axis of the 95% uncertainty ellipse has a length of ~1 km (assuming a reading error of 0.1 s on both P and S), and for the 'poorer' other events usually not more than 2 km. In Fig. 1 66 events with at least five readings (phases), and r.m.s. values <0.15 s are plotted. The epicentres are confined within an area of roughly 10 km N/S, 8 km E/W, with a concentration around 66.81 °N, 13.63° E. In view of the small location uncertainty the epicentral scatter in Fig. 1 is clearly significant, and is not an artefact of recording or data analysis. The computed depths for the 66 events are in the range 3–9 km, with 19 within 3–5 km, 27 within 5–7 and 20 within 7–9 km. Based on the computations of r.m.s. values against depth for each event, we find that the uncertainty in depth is of the same order as for the epicentral coordinates—usually within ±1 km. There is one important exception here, however, when only stations ORN, NEV and ENG are used, there is poorer resolution between shallow events to the NW and deeper events near the centre of the activated area. Finally, as the epicentres are roughly surrounded by stations, possible small errors in the crustal model are considered unlikely to adversely affect the hypocentre locations.

A study of the hypocentral 'time development' shows that essentially the whole $10 \times 8 \times 6$ km^3 volume has been activated for all the time. However, there are indications of some migrations in the earthquake activity, predominantly in a N–S direction. The southernmost and easternmost events have rather shallow depths (3–6 km), while events nearer the centre of the area cover the whole depth range of 3–9 km. The magnitude–frequency relationship for the largest events in the sequence is plotted in Fig. 4, with a non-anomalous slope of 1.13.

We have measured first-motion directions for a large number of events—not an easy task due to a 60 mm min^{-1} time resolution in our seismograms. For KIL, GLO and ORN all readings were unidirectional, while for the four other stations (see Table 1) there was one predominant direction but also observations to the contrary. At this stage it is difficult to decide whether these changes in first-motion directions are caused by either genuine differences in focal mechanisms or in hypocentral locations, or possibly also by reading errors. Notwithstanding these problems we have obtained a composite focal mechanism solution for the Meløy earthquakes as presented in the upper left corner of Fig. 1. The solution is based primarily on four events with locations along a line striking about N 10° E, each one separated by about 2 km. Two of the events were recorded by five stations, one by four stations and one by three stations, while the first-motion directions for the rest of the seven recording sites (▲) are inferred from other events with nearby locations. The solution indicates normal faulting, where the plane striking N 25° E and dipping 63° E is the one which gives the best fit to hypocentral solutions, therefore also being the probable faulting plane.

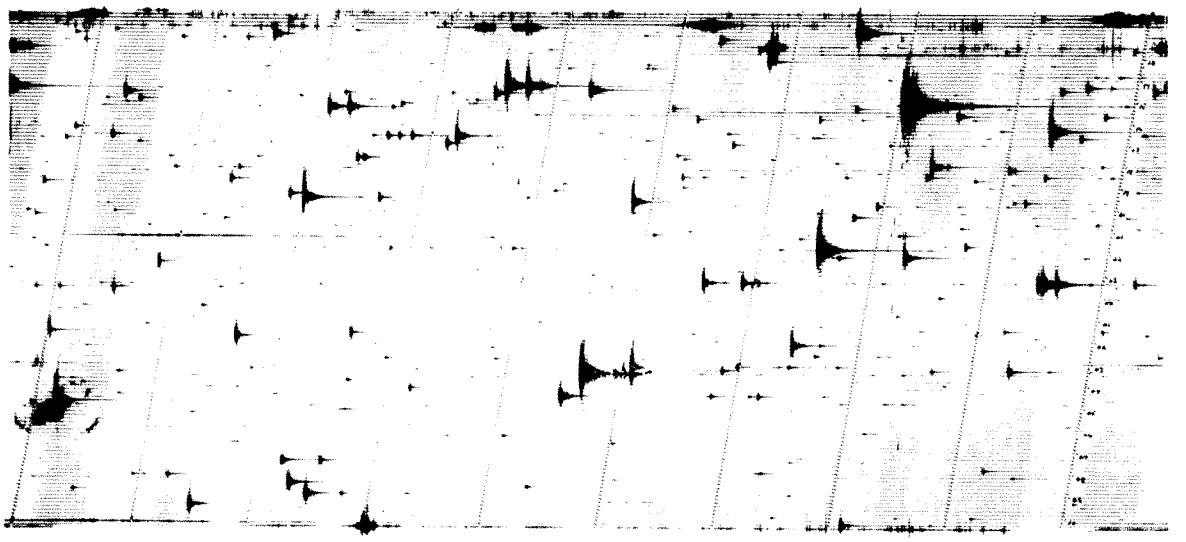

Fig. 2 Reproduction of the seismogram from station ENG covering about 24 h starting at 10.40 GMT on 2 December 1978. The earthquake swarm on the seismogram is an aftershock sequence following a magnitude (*ML*) 2.7 event at 02.04 GMT the same day, about 540 events were then recorded during the next 9 h until the onset of the reproduced seismogram, from which about 400 new events have been identified. The largest of the earthquakes on the seismogram (at 14.57 GMT) had a magnitude of $ML = 2.1$.

Macroseismic observations

Newspaper ads, instead of conventional macroseismic questionnaires[7], published during the main earthquake activity in the Meløy area (about 2,000 households along the shore lines in Fig. 1), one on 18 November covering the activity up to then and one on 30 November covering the large events on 28 and 29 November, produced 33 and 63 answers, respectively, from which we have derived a maximum radius of perception of 50 km and a maximum intensity of VI for the largest earthquakes in the sequence. This intensity was assigned to 15 of the 96 answers, all of them <10 km from the focus. In 10 of these cases damages were reported on houses, such as minor cracks in walls and chimneys.

Most of the events above *ML* = 2.0 were felt, and many more were heard. The sounds reported can be classified in three groups: (1) sounds without feeling tremor (on one occasion this was reported as a more or less continuous phenomenon over a period of several hours); (2) sounds associated with tremors, that is, simultaneous with P/S body wave arrivals; and (3) sounds associated with propagation of pressure waves through the air and from the epicentral area. The latter sounds (described as sounding like a load of snow falling off a roof) were quite different from group (2) and for the largest of the earthquakes in the sequence (28 November, *ML* = 3.2) these sounds were also observed/heard (with sufficient timing accuracy) by one of us (B.K.H.).

Discussion

The Meløy earthquake sequence is an outstanding example of intraplate seismic activity[8]. Earthquake swarm activity is not an exceptional geophysical phenomenon, as this type of process is frequently observed in volcanic areas[9,10] and also at interplate boundaries like the San Andreas fault[11]. We have not, however, been able to find a clear published counterpart to the Meløy sequence, though there are some similarities to earthquake activities reported in the Mississippi valley[12], Caucasus[13] and the Garm[14] areas.

The seismicity map for Fennoscandia in Fig. 1 shows that, although the area is not very active on the global scale, it is still far from being aseismic. Moreover, Meløy is located in the middle of a distinct seismicity zone along the coastal area between 65° and 70° N. Within this zone one of the largest events in Fennoscandia so far took place in 1819, the so-called Lurøy earthquake, with a presumed location of about 50 km south-west of Meløy. Its magnitude is estimated to 6.0–6.5m_b units, and was followed by an extensive aftershock sequence. Historical records, however, give no indications of foreshock activity.

Further west of the Meløy area (and south-west of the Lofoten Islands) there is another seismicity zone[2] which incidentally coincides with a passive continental margin (escarpment) dating back to the opening of the Norwegian Sea some 58 Myr ago[15]. The Lofoten area where the oldest rock ages are of the order of 3,500 Myr are generally considered a larger Baltic Shield fragment left mainly undeformed during the Caledonian orogeny[16], resulting in the closing of a proto-Atlantic ocean some 400 Myr BP. The seas between the two seismicity zones discussed above are part of an epicontinental basin with maximum sedimentary thicknesses of the order of 8–9 km (ref. 17). In the northern Vestfjorden sub-basin seismic profiling surveys have given clear evidence of block faulting[18]. Sometimes a causal relationship has been suggested between the Norwegian Sea opening and the contemporaneous early Eocene uplift of western Fennoscandia which amounted to a maximum of 2 km. This uplift was strongest in the central parts of Norway, tapering off rapidly westwards and gently eastwards.

A spectacular neotectonic feature is found some 200 km to the north-east in Swedish Lappland, namely, the so-called post-glacial Pärve fault[19]. The length of this fault, which is 'facing' westwards, is approximately 150 km and the maximum height is 25–30 m. Another neotectonic feature is the presumed glacial rebound of Fennoscandia, where a controversial suggestion is that this rebound has a significant tectonic component[20].

The main problem is how to fit the Meløy intraplate earthquake sequence into the tectonic framework of the area[21]. A strike direction of 20°–30° (as inferred from the epicentre distribution as well as the focal mechanism solution) is coincident with both the Caledonian folding axis, the sedimentary basin axes and that of the Pärve fault. Second, the normal faulting with an eastward dipping angle of 63° seems to rule out a causal connection both to the Eocene uplift and the present glacial rebound, having positive gradients for onshore areas. Note that the present uplift with its centre in the Bothnian Bay does not seem to correlate with Fennoscandian seismicity as discussed recently by Husebye *et al.*[2]; nor do we see a direct relationship to the off-coast sedimentary basin block tectonics

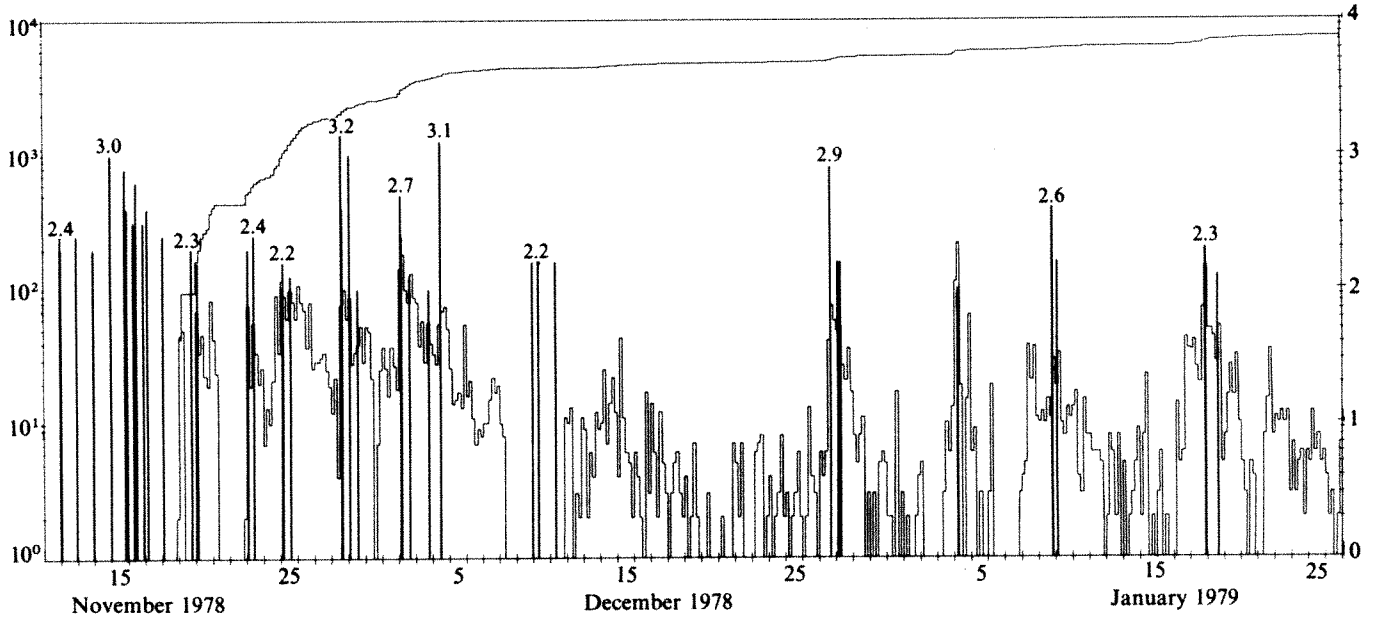

Fig. 3 Time development of the Meløy earthquake sequence as recorded at station NEV (see Fig. 1). The histogram shows the number of events on a 4-hourly basis (non-operational gaps on 21–22 November, 8–11 December 1978 and 2–3 January 1979), including the cumulative number of events and with reference to the left side scale. All events with an *ML* magnitude at 2.0 or above are plotted separately as vertical lines as referenced to the scale on the right side. For some of these larger earthquakes the magnitude is also given directly.

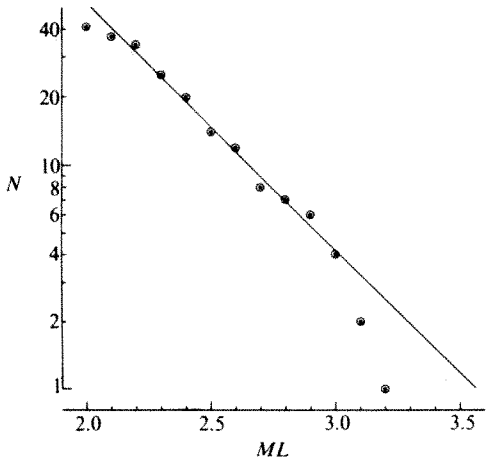

Fig. 4 Cumulative magnitude–frequency distribution for the largest events of the Meløy sequence (plotted individually in Fig. 3). The straight line is fitted by eye and satisfies the Gutenberg–Richter[6] recurrence formula ($\log N = a - b \cdot ML$) with a slope $b = 1.13$.

where the fault walls nearest to the coast face westward. However, a more subtle relationship to the off-coast sedimentary basins is possible if recent hypotheses on their formation are approximately valid[22]. The arguments here are as follows: after an initial rifting/graben formation process the sedimentary depository potential of the area in question is maintained due to continuous subsidence of the area as part of an isostatic compensation mechanism on a lithosphere whose loading response is either elastic or visco-elastic. Such a process could be associated with an 'overshoot' effect on the flanks, and in our particular case normal faulting facing eastwards. Another very generalised explanation is that in Meløy we have an exceptional example of release of remnant stresses associated with the Caledonian orogeny.

One active seismological research area is that of reanalysis of large earthquakes to investigate whether there was evidence of a precursory phenomena. In the case of Meløy the problems are somewhat different, as earthquake activity of the type reported here intuitively will be suspected as being precursory for a significantly larger event. However, in view of the exceptional nature of this intraplate earthquake sequence, it is difficult to argue convincingly either for or against such a hypothesis. If the magnitude–frequency relationship (see Fig. 4) should be used in a predictive context, we would expect a few somewhat larger earthquakes ($ML \sim 3.4$–3.6) to occur in the Meløy area. Also most processes in nature are multiplicative (exhibit a log normal distribution) so we would expect that a few events should be significantly larger than others.

We know from historical records that the general Meløy area has the potential of large earthquakes[2]. We have no firm evidence, however, of whether or not the present microearthquake activity is precursory to somewhat larger earthquake(s) to take place there in the near future. The large Lurøy earthquake of 1819 is not considered conclusive in this context as the lack of foreshocks in this case may simply reflect poor reporting practices at that time. The Meløy earthquake sequence is not only very interesting but is also puzzling, and hopefully the planned close monitoring of the area in the time to come will shed some further light on the still remaining problems.

We thank the Norwegian Polar Research Institute, Oslo, the Seismological Department, Geodetic Institute, Copenhagen, the Seismological Observatory, University of Bergen, the Norwegian Geotechnical Institute, Oslo, and Det Norske Veritas, Oslo, for cooperation. A Nilsen, NTNF/NORSAR, supervised the initial installation of recording equipment with assistance from the Meløy municipality representatives. We thank O. Fuhr, S. Gregersen, J. Hjelme, K. Hove, Y. Kristoffersen, B. Lillevik, I. B. Ramberg, P. Selnes, T. Søyland-Hansen, O. Strand and S. Vaage for assistance and discussions. This research was supported by the Royal Norwegian Council for Scientific and Industrial Research (NTNF).

Recognition and initiation site for four late promoters of phage T7 is a 22-base pair DNA sequence

Nikos Panayotatos & Robert D. Wells

College of Agricultural and Life Sciences, Department of Biochemistry, University of Wisconsin, Madison, Wisconsin 53706

T7 late promoters have a 22-base pair sequence in common. The 22 base pairs are necessary and sufficient for recognition and initiation by T7 RNA polymerase.

T7 RNA POLYMERASE, the product of viral gene 1, is a single subunit protein of molecular weight 107,000 (refs 1, 2). This enzyme exhibits almost absolute specificity for the transcription of the late T7 genes, both *in vivo* and *in vitro*[3,4]. The early promoters for the *Escherichia coli* RNA polymerase are not recognised by the T7 enzyme and even the genes of the closely related phage T3 are transcribed only poorly[5].

Transcription of intact T7 DNA with purified T7 RNA polymerase produces seven discrete transcripts initiated from promoter sites located in the 45–95% region[3,4]. Additional promoter sites at 14.2, 14.6, 18.9, 22.6, 27.9 and, possibly, at

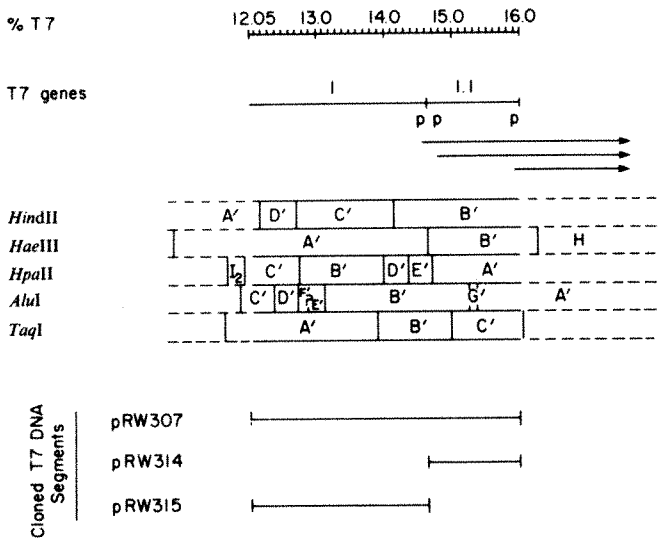

Fig. 1 Genetic and restriction map of a T7 DNA segment cloned in pRW307 (ref. 12). The restriction fragments inserted in the recombinant plasmids pRW314 and pRW315 are also indicated. The exact boundaries of the insertion in pRW307 have been determined with respect to the T7 map at 12.05% (less than 20 base pairs to the right of a *Hpa*I site at 12.03%[12]) and at 16.00% (in the middle of the *Hae*III site, as determined herein). The positions of the late promoters in this region at 14.6, 14.8 and 15.9% are indicated (p) and were identified in previous studies[8,11]. The horizontal arrows point in the direction of transcription from each promoter. The restriction fragments of the vector which flank the insertion in pRW307 are designated by unprimed letters. The junctions between the solid and dashed lines represent the boundaries of the insertion. A more detailed map is presented elsewhere[11,12].

13.5% have been recognised from transcription studies on T7 DNA restriction fragments[6,7]. The sequence of two restriction fragments containing the promoters at 14.6 and ~70% has been reported[6,8].

Recently, the presence of late promoters in cloned segments of the 12.05–18.19% region was investigated[9–11]. The several hundred-fold stimulation of T7 RNA synthesis by some of the recombinant plasmids and the lack of stimulation by others narrowed the possible location of late promoters to three small regions[10,11]. Subsequent determination of the number and size of the late transcripts synthesised off a variety of restriction fragments allowed the localisation of three late promoters inside these regions, at 14.6, 14.8 and 15.9% (ref. 11). These studies also demonstrated that late promoters were not located at 13.5 and 14.2%, in contrast with previous reports[6,7].

This article describes the sequence and template properties of two restriction fragments containing the promoters at 14.8 and 15.9%.

Isolation and sequencing of cloned promoter fragments

The T7 RNA polymerase promoters at 14.8 and 15.9% are located within *Hae*III fragment B' which spans the 14.65–16.00% region cloned in pRW307 (refs 1, 2: Fig. 1). The promoter at 14.8% is also contained within a 112 base pair *Hpa*II–*Taq*I fragment, whereas the promoter at 15.9% is contained within a 260 base pair *Alu*I–*Taq*I fragment (Fig. 1). These smaller fragments were isolated and sequenced as described in Fig. 2. Autoradiograms of typical sequencing gels of the 112 and 260 base pair fragments are shown in Fig. 2*a*, *b*, and Fig. 2*c*, *d*, respectively. The complete sequence of the 112 base pair fragment is shown in Fig. 3*a*. The first 85 base pairs from the *Taq*I site are shown for the 260 base pair fragment in Fig. 3*b*.

On the basis of the restriction mapping data obtained for the 12.05–18.19% region of T7 DNA[11,12], the sequence of the 260 base pair fragment shown in Fig. 3*b* was expected to span the region 15.8–16.0% of T7 DNA and extend past the insertion–vector junction in pRW307. (The exact end of the insertion was not known because the T7 DNA fragment had suffered a deletion during cloning[12].) The location of this junction was deduced from a comparison of the sequence in Fig. 3*b* with the published sequence of a 29-nucleotide RNA fragment transcribed from the 16.0% region of T7 DNA[13]. The sequence of the first 22 nucleotides from the 5' end of this RNA was identical with the sequence between nucleotides 50–71 of Fig. 3*b*. In contrast, the homology was lost over the next seven nucleotides. This abrupt loss of homology indicated that position 71 corresponded to the last base pair of the T7 DNA insertion before the vector junction in pRW307. The deletion of T7 DNA beyond nucleotide 71 caused the loss of the right half of a *Hae*III site (GG ↓ CC) that is evident in the sequence of the RNA and has been mapped by F. W. Studier (personal communication) at 16.00% of the T7 genome. Thus, the restriction map of T7 DNA and the homology with the sequence of the short RNA are both consistent with the assignment of the end of the insertion at 16.00%.

The T7 fragment in pRW307 was inserted into the *Hpa*I site of the pRT29 vector[12]. The sequence of the vector-half of this site corresponds to nucleotides 72–74, indicating that the vector remained intact at this site, in agreement with the conclusions drawn from the restriction analysis data[12].

A recognition–initiation site for T7 RNA polymerase

Our previous studies have shown that two late promoters are located at 14.8 and 15.9% of the T7 genome[11], that is, within the sequences of the 112 and 260 base pair fragments shown in Fig. 3. Measurements of the lengths of the transcripts initiated at these promoters and terminated at various restriction sites downstream, placed the initiation points at ~93 and ~35 nucleotides to the left (upstream) of the *Taq*I sites of the 112 and 260 base pair fragments, respectively[11]. The initiation points for these transcripts were more accurately determined from the data shown in Fig. 5 (lane *a*). The lengths of the transcripts shown in this figure were determined to be 93±4 and 47±2 nucleotides. These sizes place the initiation point at a corresponding number of base pairs upstream from the *Taq*I sites, within positions 16–24 of the 112 base pair fragment (Fig. 3*a*) and positions 37–41 of the 260 base pair fragment (Fig. 3*b*).

Inspection of the sequences around these two regions immediately revealed the presence of a nearly identical sequence of 23 contiguous nucleotides TAATACGACTCACTATAGGPuPuNA between positions 5–27 and 22–44 in Fig. 3*a* and *b*, respectively.

Comparison of this sequence with the published sequences of the promoters at 14.6 and ~70% (refs 6, 8) revealed almost complete homology, for the region around and immediately upstream from the transcription initiation site (Fig. 4). On the basis of these four structures, the following DNA sequence is proposed for the recognition–initiation site for T7 RNA polymerase:

5' AATACGACTCACTATAGPuPuPuNA 3'

In proposing this sequence, only nucleotides identical in all four promoters were considered, with the following two exceptions: (1) Position −5 of the promoter at 15.9% is a G rather than a C. We have assumed this transversion to be a feature of this particular promoter, and believe it to be responsible for the approximately fivefold lower activity observed relative to the promoters at 14.6 and 14.8% (ref. 11). (2) Position −16 of the promoter at ~70% reads C rather than A. Because the other three sequences have an A at this position, we have assumed that the A→C transversion is a deviation from the general structure. It may be of interest to determine the strength of this promoter relative to the others.

For consistency, we have chosen to include in the general structure the adenosine at position +6, although the continuity of the homology is interrupted at position +5. The preservation

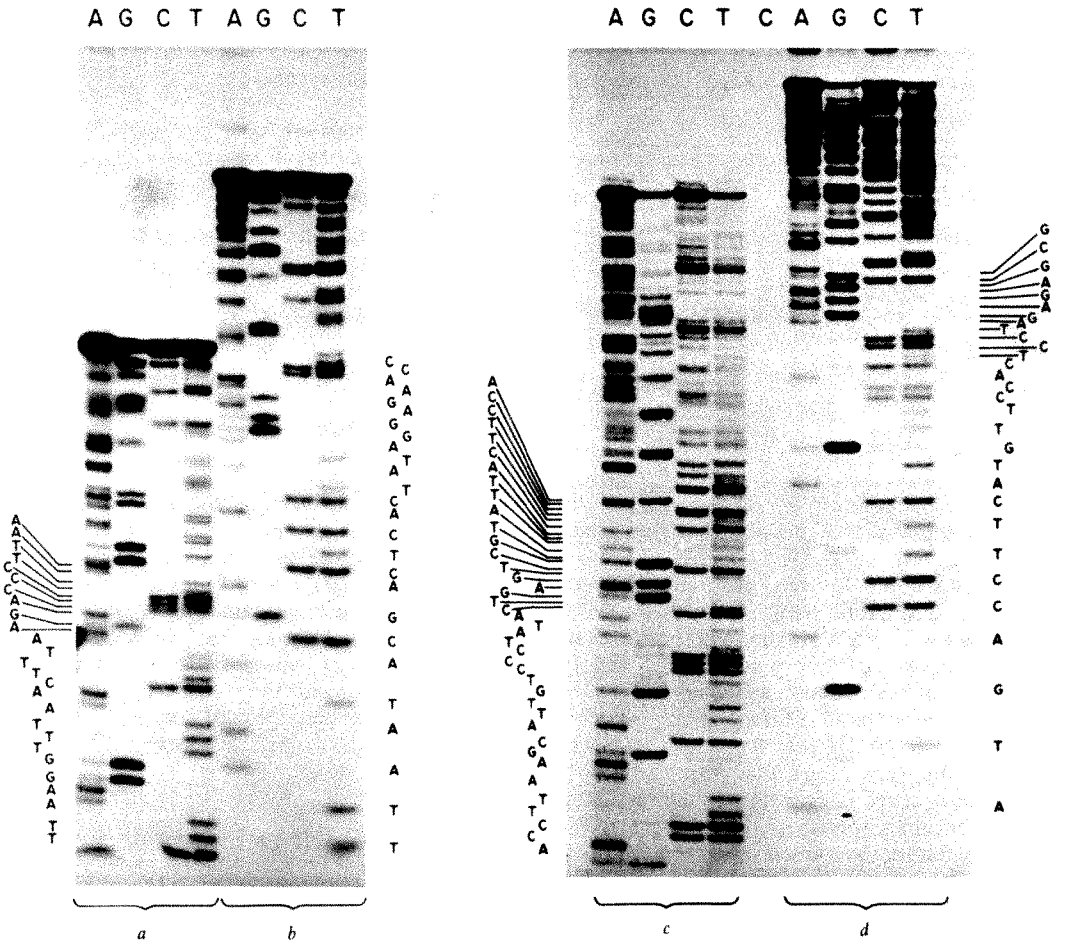

Fig. 2 Autoradiograms of sequencing gels of two promoter-containing fragments of T7 DNA cloned in pRW307. *Hae*III fragment B′ (Fig. 1) was purified from a *Hae*III + *Eco*RI digest of pRW307 by RPC-5 column chromatography[14]. This fragment was digested with *Hpa*II, labelled at the 5′ ends with T4 polynucleotide kinase and redigested with *Taq*I. These reactions produced a 23 base pair *Hae*III–*Hpa*II fragment, a 112 base pair *Hpa*II–*Taq*I fragment containing the promoter at 14.8%, a 409 base pair *Taq*I fragment C′ and a 99 base pair *Taq*I–*Hae*III fragment. These fragments were fractionated on 8% polyacrylamide gels and visualised by autoradiography and ethidium staining. The 112 base pair fragment labelled at the 5′ end of the *Hpa*II site was recovered from the gel and sequenced. Lanes *a* and *b* show an autoradiogram of a typical sequencing gel for this fragment. The complete sequence of the *Hpa*II–*Taq*I fragment which spans the region 14.70–15.00% of T7 DNA is shown in Fig. 3*a*. The promoter at 15.9% is contained within a 260 base pair *Alu*I–*Taq*I fragment which was isolated and sequenced as follows. The purified *Hae*III fragment B′ was digested with *Taq*I, labelled at the 5′ ends with T4 polynucleotide kinase and redigested with *Alu*I. These reactions produced a 135 base pair *Hae*III–*Taq*I fragment, a 104 base pair *Taq*I–*Alu*I fragment a 45 base pair *Alu*I fragment G′, a 260 base pair *Alu*I–*Taq*I fragment containing the promoter at 15.9%, and a 99 base pair *Taq*I–*Hae*III fragment. These fragments were fractionated on 8% polyacrylamide gels and visualised by autoradiography and ethidium staining. The 260 base pair fragment (labelled at the *Taq*I site) was eluted from the gel and sequenced. An autoradiogram of a typical sequencing gel for this fragment is shown in lanes *c* and *d*. The sequence of the first 88 nucleotides from the *Taq*I site is shown in Fig. 3*b*. The sources of the enzymes and the procedures for the restriction reactions, end-labelling, gel elution and sequencing gel electrophoresis were based on published procedures[15] and have been described[11,12].

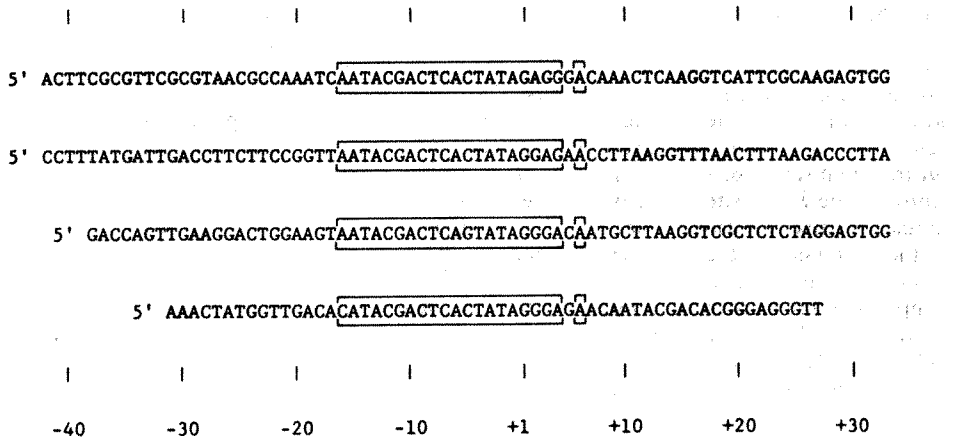
Fig. 3 DNA sequence of promoter-containing fragments. *a*, Nucleotide sequence of the 112 base pair *Hpa*II–*Taq*I fragment spanning the region 14.70–15.00% of T7 DNA. This fragment was isolated from a larger cloned segment of T7 DNA and sequenced as described in the legend to Fig. 2. *b*, Nucleotide sequence of part of the 260 base pair *Alu*I–*Taq*I fragment showing the region 15.82–16.00% of T7 DNA and 17 base pair of vector DNA at the *Taq*I end. This fragment was isolated from a longer, cloned segment of T7 DNA and sequenced as described in Fig. 2. Positions 70–71 correspond to the vector–insertion junction at 16.00% of T7 DNA. Positions 69–73 cover half of the *Hae*III site of T7 and half of the *Hpa*I site of the vector (see text).



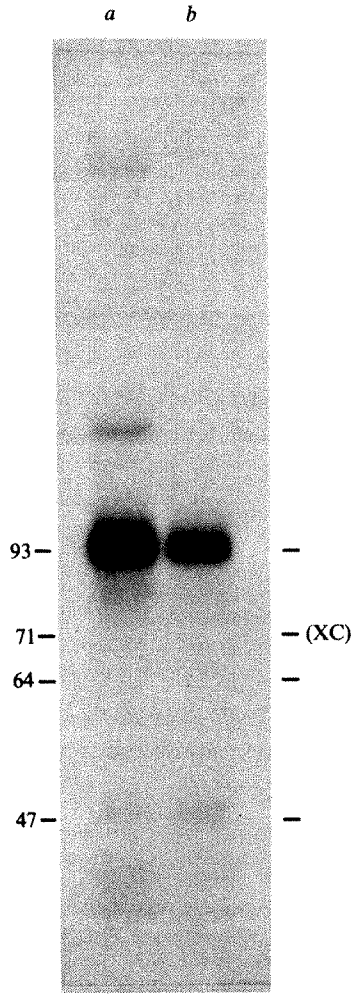


Fig. 4 DNA sequence around the T7 late promoters located at 14.6 (ref. 6), 14.8 (this report), 15.9 (this report) and ~70% (ref. 8) of the genome. The highly preserved sequence which constitutes the recognition–initiation site is indicated by the solid lines. Positions are marked from the initiation point at +1. The complete DNA sequence between the promoters at 14.6 and 14.8% is shown on the top two lines, interrupted at the *Hae*III site (at 14.65%) for clarity.

of adenosine at position +6 may not be fortuitous but may be due to an important contact of the polymerase with this nucleotide.

The DNA region between positions −16 and +6 around the transcription initiation point is proposed to constitute a recognition site for T7 RNA polymerase because of its highly preserved sequence in the four promoters examined thus far. Random occurrence of the common sequence in T7 DNA is extremely unlikely. (The probability for a 16 base pair sequence to occur 4 times in T7 DNA (40,000 base pairs) is 8×10^{-16} (W. Fitch, personal communication). The probability for the 22 base pair common sequence is even lower but calculation of the exact number becomes complicated by the possible variation in the PuPuPuN part of the sequence.) However, this region might not contain all pertinent structural elements. If nucleotides outside the common sequence also contributed structural information necessary for recognition, their positions should also have been preserved among the four sequences. Inspection of the nucleotides outside the common sequence (Fig. 4) shows that the same nucleotide does not appear at a given position more than twice, with the exception of the adenosine at −19 and the thymidine at +21, which appear three times. This complete lack of homology outside the −16 to +6 region, as opposed to the almost complete preservation of homology inside, suggests that positions −16 to +6 constitute a necessary and sufficient recognition–initiation site.

Further identification of the promoter

Direct evidence to support the previous conclusion comes from the results of cloning experiments. In pRW315, the T7 DNA region beyond the *Hae*III site at position +33 of the 14.6% promoter was substituted by vector DNA. In pRW314, the T7 DNA region ahead of the *Hae*III site at position −42 of the 14.8% promoter was also substituted by vector DNA (Figs 1 and 4). Despite the substitution of the natural viral sequences by vector DNA, the activity of these promoters in pRW314 and pRW315 was not significantly reduced relative to their activity in pRW307 (ref. 11).

Similar conclusions were reached when purified *Hae*III fragments A′ and B′ were assayed[11]. In both cases, discrete transcripts were obtained at comparable yields from the promoters at 14.6 and 14.8%, indicating that the absence of DNA upstream from position −42 and downstream from position +33 from the initiation point was not required by T7 RNA polymerase.

Fig. 5 Autoradiogram of ^{32}P-labelled transcripts fractionated on a 8% polyacrylamide–7 M urea gel. RNA was synthesised with highly purified T7 RNA polymerase (0.15 μg of fraction V; the gift of G. Kassavetis and M. Chamberlin[7]) as described previously[11]; 0.75 μg of either *Hae*III fragment B′ digested with *Taq*I (lane *a*) or *Hae*III fragment B′ digested with *Taq*I + *Hpa*II (lane *b*) was used as the template. The heaviest bands in both lanes *a* and *b* correspond to 93 ± 4 base transcripts[11] initiated at the 14.8% promoter and terminated at the *Taq*I site. The weak bands near the bottom of the gel correspond to 47 ± 2 base long transcripts initiated at the 15.9% promoter and terminated at a *Taq*I site. The ~5 × weaker expression of the 15.9% promoter relative to the 14.8% promoter (as judged by band intensity) is consistent with previous observations[11] and is attributed to a variation in the structure of the 15.9% promoter (see text). The weak band in the upper half of the gel in lane *a* apparently represents an end-to-end transcript synthesised off the 135 base pair *Hae*III-*Taq*I fragment. When this fragment is cleaved by *Hpa*II 23 base pairs from the *Hae*III site upstream from the 14.8% promoter, this band disappears (lane *b*). A 64 base transcript synthesised by *E. coli* RNA polymerase off a 203 base pair *Hae*III fragment containing the *lac* UV5 promoter was also used as a marker[20]. Its position, as well as the position of xylene cyanol which migrates as a 71-base long transcript on this gel, is indicated.

Further evidence on the boundaries of the sequence that defines a T7 late promoter was obtained from transcription studies (Fig. 5) of the 112 base pair *Hpa*II–*Taq*I fragment (at 14.70–15.00% in Fig. 1) in which the DNA sequence ends just 4 base pairs upstream from the recognition site (Fig. 3*a*). The activity of the 14.8% promoter in this fragment was determined relative to the 135 base pair *Hae*III–*Taq*I fragment (at 14.65–15.00%) in which the T7 DNA extends through the *Hpa*II site upstream to the *Hae*III site (Fig. 1). Each reaction mixture also contained *Taq*I fragment C' (Fig. 1); thus, the expression of the 15.9% promoter in the latter fragment served as an internal control. In identical assay conditions, comparable amounts of discrete transcripts (~93 bases long) were synthesised from the 14.8% promoter in either the *Hpa*II–*Taq*I or the *Hae*III–*Taq*I fragments. In both cases, the 47-base transcript from the 15.9% promoter control was expressed to a similar extent. This result demonstrated that elimination of the DNA as close as 4 base pairs upstream from the common promoter sequence had no effect on the efficiency or selectivity of transcription.

In summary, the lack of homology outside the 22 base pair common sequence indicates that the neighbouring DNA structure did not contribute directly to recognition. The results of experiments in which the DNA upstream or downstream from the common sequence was either replaced by foreign DNA or removed are consistent with this interpretation. By these criteria, the 22 base pair contiguous sequence constitutes a fully defined recognition–initiation site for T7 RNA polymerase.

Comparison with other promoters

The sequence of the recognition site contains very little two-fold symmetry. Only the 6 base pair sequence between positions −5 and +1 is symmetrical and additional symmetry around the same axis depends on the particular nature of the nucleotides in the –PuPuPuN– part of the sequence. In this regard, the 14.6% promoter contains much more symmetry than the 14.8% promoter, but this feature does not seem to affect the relative expression of these two promoters. The lack of extensive two-fold symmetry is also observed with bacterial promoters[16].

In promoters for *E. coli* RNA polymerase, a 7 base pair site of partially preserved sequence (the 'Pribnow box') is located 7 base pairs upstream from the transcription initiation point[17]. A second region of partially preserved sequence also exists approximately 30 base pairs further upstream and mutations in this region affect promoter function[16,18]. In contrast, T7 promoters consist of one contiguous recognition site, which includes the initiation point and no other sequence further upstream, seems to be required for complete function. In this respect, T7 promoters are quite distinct from their bacterial counterparts. The physical separation of the two recognition sites and the initiation site in the *E. coli* promoters, as opposed to the condensation of these elements into one contiguous site in T7 promoters, may reflect the size difference between the two enzymes (the *E. coli* polymerase is about five times larger than the T7 RNA polymerase).

The possibility has been raised that bacterial promoters may be located at easily denatured, A+T-rich regions of the DNA template[19]. Such a correlation was also proposed for T7 late promoters[5]. The unusually high (69%) A+T content of the 112 base pair fragment containing the promoter at 14.8% agrees with this model. However, neither the promoter at 14.6% nor the promoter at 15.9% are located in unusually A+T rich regions. (A+T = 52% for both *Hpa*II fragment E' and the 71 base pair T7 segment around 15.9% in Fig. 3*b*.) Thus, A+T richness does not seem to be a general property of T7 promoter sites. The unusually high A+T content of the 14.7–15.00% region may be important for some other regulatory site in the vicinity of this region, such as the origin of T7 DNA replication[12].

Noted added in proof: M. Rosa[21] has recently reported that four class *3* T7 late promoters share the same sequence.

On the detection of large-scale inhomogeneities in the Universe

THE detection of large-scale inhomogeneities in the Universe has proceeded along a number of fronts. The observed spatial distribution of galaxies indicates clumping of matter on length scales up to ~30 Mpc (ref. 1). Limits on fine-scale temperature fluctuations in the microwave background[2] constrain mass concentrations at the epoch of recombination, and later[3,4]. Neither of these methods is particularly sensitive to large-scale low-density contrast ($\delta\rho/\rho \ll 1$), perturbations at the current epoch (that is, masses $\gg 10^{19} M_\odot$ on a scale $\geq$1,000 Mpc), although in principle the distribution of discrete radio sources on the sky may be investigated for such effects (see for example ref. 5). We show here that measurements of the isotropy of the X-ray background provide a sensitive means of detecting such large-scale inhomogeneities within $z \sim 5$.

A matter perturbation, with excess mass δM, retards the motion of our Galaxy relative to the overall expansion of the Universe with a peculiar velocity δv_G given, from energy considerations, by

$$v_G \delta v_G \simeq \frac{G\delta M}{r} \qquad (1)$$

Here the perturbation is at a distance r from our Galaxy and v_G is the Hubble flow velocity over that distance. We then obtain

$$\delta v_G \simeq \frac{1}{2}\left(\frac{\delta\rho}{\rho}\right)\Omega H_0 \frac{l^3}{r^2} \qquad (2)$$

where Ω is the cosmological density parameter ($8\pi G\rho/3H_0^2$),

0028–0836/79/270039—02$01.00

© Macmillan Journals Ltd 1979

$\delta\rho$ is the excess matter density and l is the size of the perturbation.

Other cosmological effects are small, and can be neglected, provided that $(\delta\rho/\rho) \ll 1$ and r corresponds to a redshift $\leqslant 1$. The peculiar velocity of the Galaxy then induces a 24-h variation[6] in the microwave background through the Compton–Getting effect;

$$I = (2-\alpha)\left(1+\frac{\delta v_G}{c}\cos\theta\right)I_0 \qquad (3)$$

where θ is measured from the direction towards δM, and α is the photon number spectral index of the radiation. ($\alpha = 1$ for the Rayleigh–Jeans part of the microwave spectrum and ~ -1.4 for the X-ray spectrum; $2 < E < 20$ keV.) Twenty-four-hour anisotropy in the microwave background, implying a peculiar velocity of 600 km s^{-1}, has been reported by Smoot *et al.*[7] after correcting for the rotation of the Galaxy.

The microwave background originates at $z \sim 10^3$, whereas the X-ray background probably originates from within $z \leqslant 3$. Only weak evolution of the known classes of X-ray source[8] (particularly quasars and active galaxies) is needed to explain the observed intensity. If $r \ll cH_0^{-1}$ (that is if the redshift of the matter perturbation $z_M \ll 1$), then a similar 24-h variation may be expected in both the X-ray and microwave backgrounds. On the other hand, if $r \sim cH_0^{-1}$, δM generates large-scale shear across the Universe out to $z \sim 1$ and the X-ray background varies in a significantly different manner. A 12-h variation, peaking at $\theta \sim 90°$, is predicted as shown in Fig. 1. The sources of the X-ray background between ourselves and the mass are decelerating more rapidly than we are and are thus seen to be receding. In the opposite direction we are decelerating more than the background, which also gives a recession. Only in intermediate directions is our velocity and that of the background comparable. The 12-h effect reduces if r is much greater than cH_0^{-1}. The peculiar velocity δv_r of the Galaxy relative to a shell of X-ray emitting matter at distance d is given, from (2) as

$$\delta v_r \simeq \delta_{vG}\left(\cos\theta + \frac{(d/r - \cos\theta)}{(1+(d/r)^2 - 2(d/r)\cos\theta)^{3/2}}\right) \qquad (4)$$

This gives a 12-h variation through equation (3) with $\delta v_G \cos\theta$ replaced by δv_r. The overall effect on the X-ray background may be further complicated by any X-ray emission from δM itself, and by the rotation of the Galaxy together with any other local peculiar velocities.

An oblate 12-h variation in the X-ray background can thus, in principle, measure large-scale shear over distances out to $z \sim 1$. The net differential velocities between different directions need not exceed more than a few hundred km s^{-1} before giving a detectable X-ray signal. This is a consequence of the fact that the X-ray background provides an absolute measurement of integrated quantities out to $z \sim 1$. This has been noted by Wolfe[9] in constraining world models with shear using the 1% limit to 12- and 24-h variations in the X-ray background placed by Schwartz[10]. The Leicester Sky Survey Instrument on Ariel V can detect such variations at the level of ~0.5% (ref. 11).

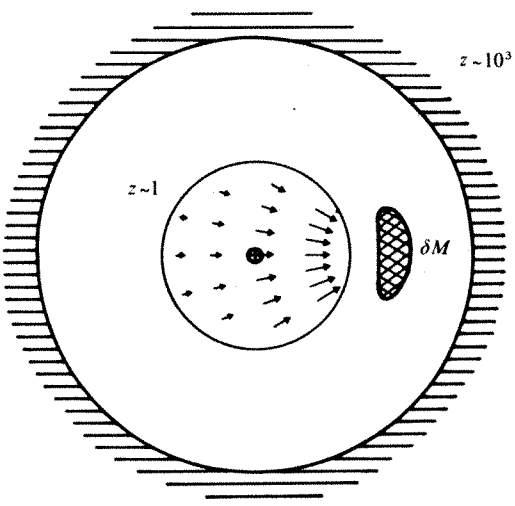

Fig. 1 Schematic representation of tidal gravitational influence of density inhomogeneity, mass δM, on the velocity shear of the X-ray background.

The 12-h isotropy of the X-ray background is most sensitive to masses situated at $z_M \sim 1$;

$$\delta M \simeq 10^{20} z_M^2 H_{50}^{-1} \delta v_6 \qquad M_\odot$$

with size

$$l \simeq 1{,}000\left(\frac{\delta\rho}{\rho}\right)^{-1/3} z_M^{2/3} H_{50}^{-1} \delta v_6^{1/3} \Omega^{-1/3} \qquad \text{Mpc}$$

where $\delta v_G = 600\,\delta v_6$ km s^{-1}, $H_0 = 50 H_{50}$ km s^{-1} Mpc^{-1}.

A large-scale density inhomogeneity, with $(\delta\rho/\rho) \sim 0.01$ now, corresponds to $(\delta\rho/\rho) \sim 10^{-5}$ at the epoch of recombination. We conclude that the combination of microwave and X-ray background anisotropy observations will enable us to study the very large scale structure of the Universe at the current epoch.

The possibility of accretion onto radio pulsars

AS an explanation for the observed long-term variations in pulsar emission[1–3], an accretion model is proposed here which permits interstellar neutral hydrogen to infiltrate the light-cylinder and, following ionisation, to modulate the pulsed emission. This would suggest that pulars have an eventful passage through the interstellar medium, and do not always remain as pulsars.

The widely accepted picture of a pulsar is that of a magnetised neutron star rotating in a vacuum[4]. The intense electric fields thereby induced are supposed to remove charged particles from the surface near the magnetic poles and accelerate them to high energies[5]. The radiation generated by these particles then interacts with the local magnetic field to produce cascades of electron–positron pairs[6,7], whose emission we observe. The site of the emission is still unclear. Around the light-cylinder the rotating magnetic field produces a strong electromagnetic wave whose pressure prevents the interstellar medium from moving into the magnetosphere. In all emission models based on this general picture it is vital that the region inside the light-cylinder be maintained as a near-vacuum.

Theoretical attention is usually concentrated on explaining emission features which have time scales of the order of the neutron star rotation period or less[6,8] (microstructure[9], for example). Instabilities of the flow between the magnetic poles

0028–0836/79/270040—02$01.00

© Macmillan Journals Ltd 1979

and the light-cylinder are seen as a natural explanation for such short time-scale modulations. It has been observed, however, that both individual and integrated pulse intensities are also strongly modulated on every time scale from hours to years[1,2]. Recently, substantial day-to-day changes in the spectra of nine pulsars have been reported[3]. It is difficult to see how such long-term variability can be achieved by any mechanism whose fundamental time scale is the period of rotation. On the other hand, the shape of the integrated profiles and their polarisation are generally stable[10] (although even here occasional 'mode-changing' occurs[11]). The overall impression is that a basic emission pattern is being modulated by some external influence.

The Solar System was once thought to be insulated from the interstellar medium by the shielding effect of the solar wind[12]. Later work has shown that the Solar System is in fact penetrated by interstellar hydrogen atoms[13]. This is made possible by the relative motion of the Sun and the interstellar medium (about 15 km s^{-1}). One is led to speculate whether pulsars, whose velocities are often well in excess of 100 km s^{-1}, may be subject to such a process.

The radius, R_w, of a pulsar's wave-zone is given by the condition

$$\frac{\dot{E}}{4\pi R_w^2 c} \sim \frac{B_0^2}{8\pi}$$

where $\dot{E}$ is the spin-down energy loss-rate and B_0 is the ambient interstellar magnetic field. Taking $\dot{E} \sim 10^{31}$ erg s^{-1} and $B_0 \sim 5\times10^{-6}$ G, we obtain $R_w \sim 5\times10^{15}$ cm. By comparison, the mean free path of a hydrogen atom with respect to ion collisions is $\lambda \sim 1/(n_i\sigma)$, where n_i is the ion density and σ the collisional cross-section. Taking $n_i \sim 0.03$ cm^{-3} and $\sigma \sim 3\times10^{-15}$ cm^2 we obtain[14,17] $\lambda \sim 10^{16}$ cm. Thus $\lambda > R_w$ at least for weaker (low period change $\dot{P}$) pulsars and, although ions will be deflected by the strong wave, neutral hydrogen atoms can pass insensibly through the interface between the interstellar medium and the wave and move on hyperbolic orbits towards the neutron star.

The highly energetic particles emitted by the pulsar present no threat to the oncoming atoms, both because of their extremely low cross-sections ($\sim10^{-18}$ cm^2) and low density ($\ll 1$ cm^{-3}) outside the light-cylinder. But thermal UV radiation from the star's surface may be more dangerous. It can be shown that an atom travelling at 100 km s^{-1} will survive against photoionisation until it enters the light-cylinder radius ($\sim5\times10^9$ cm) only if the surface temperature has fallen below 10^5 K. On favourable assumptions, this temperature may be reached within 0.1 Myr of the formation of the neutron star[15]. Similar conclusions have been reached independently by Tsygan[16].

If an atom is ionised before reaching the light-cylinder, it will be driven out of the magnetosphere by the pulsar's strong wave. But if ionisation takes place within the light-cylinder (through interaction either with the thermal or the beamed radiation) it can play a role similar to that ascribed in some models[6,7] to pair-creation: one of the two resulting charged particles will, if on an open field-line, be pulled to the polar cap by the electric field, whilst the other will be accelerated outwards and expelled. If charged particles can be supplied in sufficient numbers, the electric field parallel to the magnetic field-lines will be 'short-circuited'. This would result in the breakdown of any emission mechanism which requires particles to be removed from the surface.

For a pulsar of period P moving with a velocity V through a medium of density n_H the rate of accretion of neutral particles into the light-cylinder radius, R_L, is $\pi R_L R_A V n_H$, where R_A is the 'accretion radius' of the neutron star defined by $R_A = 2GM/V^2$. This is the appropriate formula when $\lambda \gg R_A$. Taking $M \sim 1.4\,M_\odot$, $V \sim 100\,V_{100}$ km s^{-1}, we obtain the accretion rate

$$\dot{N}_A \sim 5.6\times10^{29}\frac{Pn_H}{V_{100}} \quad \text{s}^{-1}$$

To eliminate the electric field along the magnetic fieldlines we require a charged particle flux of $(\pi R_P^2)(B/\text{Pec})c$, where B is the polar magnetic field strength and R_P the cap radius (whose circumference is defined by the fieldlines which just touch the light-cylinder). With $R_P \sim 1.4\times10^4/P^{1/2}$ cm and $B \sim 10^{12}$ G the necessary particle flux is

$$\dot{N}_p \sim \frac{1.3\times10^{30}}{P^2} \quad \text{s}^{-1}$$

For the typical values $P \sim 1$ s and $n_H \sim 1$ cm^{-3}, $\dot{N}_A$ is a significant fraction of $\dot{N}_P$ and disturbance of the emission pattern can be expected. Comparing the expressions for $\dot{N}_A$ and $\dot{N}_P$, we see that this effect is more likely to be pronounced in high-period, low-velocity pulsars. A further consequence is that fast-moving pulsars (through a lower accretion rate) may actually 'live' longer than slow-moving pulsars.

Long-term variations in emission can be interpreted, through variations in n_H, as the result of inhomogeneities in the interstellar medium. It is therefore possible to regard pulsars as monitors of the detailed structure of the gas in their neighbourhood. Furthermore, one might question the usual anthropomorphic assumption of a single uninterrupted lifespan for each pulsar. It is believed[17] that the Solar System has passed through many neutral hydrogen clouds in the 5×10^3 Myr since its formation. In its much shorter life ($\sim$2 Myr) a fast-moving pulsar will also have led a chequered existence, passing through clouds of various densities. The calculations here suggest that even a 'standard' H I cloud[18] ($n_H \geq 10$ cm^{-3}) can switch a pulsar off. A pulsar moving at 100 km s^{-1} covers 200 pc in 2 Myr. On current estimates[17], 12 pc of this (or 6%) will be spent in clouds with $n_H \geq 10$ cm^{-3}. There are now over 300 known pulsars, so there might be 20 single neutron stars which would otherwise have been detectable as pulsars at present immersed in dense H I regions. Pulsars are probably born in or near OB associations, so they are more likely to be surrounded by gas in their early lives and it may be significant that no pulsar has yet been found in a supernova remnant shell.

Accretion onto neutron stars suggests affinities between the model given here and the so-called X-ray 'bursters' (especially those which have yet to reveal evidence of being in a binary system[19]). These are often of a transient nature, inviting comparison with the 'nulling' phenomenon of radio pulsars, whereby emission ceases abruptly at all wavelengths. The time spent in the null state varies from pulsar to pulsar, but values of over 50% have been given for some pulsars[20]. There is evidence[20] that nulling is more common in long-period pulsars, as would be expected from the above accretion rate estimates ('drifting subpulses'[21], which are often associated with nulling, may therefore also be related to accretion). The time spent in a null sequence might sometimes be related to the energy of the following or preceding stretches of emission (as in MXB1730−335)[19].

I thank H. J. Fahr, M. Walmsley, P. Biermann and the members of the Bonn pulsar group for helpful discussions.

The size of Jupiter's electrically conducting fluid core

WHEN the magnetic field of a planet is due to hydromagnetic dynamo action in an electrically conducting fluid core surrounded by a poorly conducting mantle, Hide's[1] method can, in principle, be used to determine the radius r_c of the core from determinations of secular changes in the magnetic field **B** in the accessible region above the surface of the planet, mean radius r_s ($\geq r_c$). It will be possible to apply this method to Jupiter (and other planets) when magnetic measurements of sufficient accuracy and detail become available. We describe here a preliminary study in which we have analysed the magnetic measurements made in December 1973 and December 1974 when the Pioneer 10 and Pioneer 11 fly-by space-probes encountered Jupiter[2]. We expected that over such a short time interval any true secular changes would be masked by errors and the corresponding estimate of r_c/r_s highly implausible or even physically impossible, but this turns out not to be the case. Taken at their face value the apparent secular changes in the dipole and quadrupole components of Jupiter's magnetic field imply that r_c/r_s is close to 0.7. Somewhat higher values of r_c/r_s are found when contributions from the octupole component are also included.

Jupiter is the largest known planet. It has a mean radius r_s of 6.97×10^7 m, more than 10 times that of the Earth, and a mean density of 1,330 kg m^{-3}, close to that of the Sun and about a quarter of that of the Earth. At about 5×10^{12} Pa (50 Mbar), Jupiter's central pressure is more than 10 times that of the Earth and this ensures that Jupiter's main chemical constituent, hydrogen, is metallic throughout most of the planet. Only above the level $r=r_m$ (r being the distance from the centre of the planet), in the 'mantle' and the 'atmosphere' where the prevailing pressures are less than a certain pressure of a few megabars, does hydrogen take its more familiar molecular form. This transition pressure is not yet known to much better than a factor of two and the corresponding estimates of r_m/r_s given in the recent literature range from 0.7 to 0.8. The planet is generally considered to be fluid throughout[2-4].

The existence of a strong jovian magnetic field of internal origin and nearly dipolar form, with a dipole moment about 10^4 times the magnitude of and opposite in sign to that of the Earth's present field, was first inferred in the 1950s from radio-astronomical observations at decametre and decimetre wavelengths[2]. Important details of the field were obtained by Smith, Davis and Jones, and by Acuña and Ness from *in situ* magnetometer measurements on board the Pioneer 10 and Pioneer 11 space probes[2] and further details are expected from measurements on board Voyager 1 spacecraft, which passed close to Jupiter very recently (1–5 March 1979) and Voyager 2, which will encounter Jupiter later this year (2–9 July).

The only serious suggestion as to the origin of Jupiter's magnetic field closely parallels ideas developed by geophysicists over the past 30 years towards an explanation of the Earth's magnetism[2,5]. Thus, we can suppose that the jovian field is due to ordinary electrical currents circulating in the conducting regions within the planet and that these currents are produced by the hydromagnetic dynamo process, involving inductive interactions between fluid motions and the magnetic field. Whether dynamo action is possible depends *inter alia* on the value of the so-called magnetic Reynolds number

$$R\equiv\sigma\mu LU \qquad (1)$$

where R is the ratio between the time scale of free ohmic decay $\sigma\mu L^2$ and an advective time scale L/U; L is a typical length scale; U is a typical flow speed associated with the fluid motions, and σ and μ are average values of the electrical conductivity and magnetic permeability of the electrically conducting core of outer radius r_c within which dynamo action is hypothesised to occur. Such action is impossible when R is very small for then motional induction cannot overcome the effects of ohmic dissipation, and also when R is infinite as the magnetic flux linkage of a perfect electrical conductor cannot change. The most efficient dynamos occur when R has some optimum value $\bar{R}$ where typical values of $\bar{R}$ range between 10 and 100.

It is tempting to assume that r_c is equal to r_m, the radius of the metallic core, as it would be if the mantle of Jupiter were a very good insulator. But the value of σ required to make $R=\bar{R}$ might be a good deal less than the high values (typically greater than $10^6\ \Omega^{-1}\ m^{-1}$) found in the metallic core, and it is conceivable that impurities and high pressure and temperature render the lower reaches (at least) of the molecular hydrogen mantle sufficiently conducting to support dynamo action there, in which case r_c would be significantly greater than r_m (refs 2, 4, 5).

The new method[1,6] which estimates r_c with a typical error of the order of but greater than $r_c/\bar{R}$, has been applied to the Earth, using the best determination of the geomagnetic secular variation for the period 1955–75 expressed in terms of a spherical harmonic series truncated at degree $n=n^*=8$. Values of r_c were obtained differing by typically 10% or 15% from the radius of the liquid metallic core as determined from seismological data. (The agreement to within 2% for the first epoch considered has been checked and confirmed but the subsequent analysis of data from other epochs suggests that 2% is atypically low[7].) When sufficiently accurate measurements of the magnetic fields of other planets (for which seismological data are not available) have been made, it should be possible to use the method in the investigation of their interiors. The Pioneer 10 and Pioneer 11 measurements of Jupiter's magnetic field[2] are not, however, considered to be sufficiently accurate and detailed to give reliable information on secular changes in **B** during the short interval of only one year between the times $t=t_{10}$ and $t=t_{11}$ (say) of the two encounters[2]. We expected that these uncertainties would manifest themselves as highly improbable or even physically impossible values of r_c based on these limited measurements but surprisingly we found this was not the case.

Smith *et al.*[2] have constructed several spherical harmonic models of the jovian magnetic field for $t=t_{10}$ and $t=t_{11}$. These are based on the vector helium magnetometer observations on board Pioneer 10 and Pioneer 11 made within $8r_s$ of the centre of Jupiter, in the region of the inner magnetosphere where the contribution to **B** made by local currents should be negligible. For the inner magnetosphere **B** consists of an 'internal' part originating within the planet and a smaller 'external' part due to electrical currents flowing in the middle and outer magnetosphere or in the magnetopause. Smith *et al.*[2] give for each of the Pioneer 10 and Pioneer 11 data sets four spherical harmonic models, each comprising sets of coefficients for the field of internal origin up to degree and order n_i and for the field of external origin coefficients up to degree and order n_e, as follows: (a) $n_i=3$, $n_e=2$; (b) $n_i=3$, $n_e=1$; (c) $n_i=3$, $n_e=0$; (d) $n_i=2$, $n_e=2$. For each of the four pairs of models we have calculated the total 'unsigned' flux through spheres of various radii $r=r_s(1-0.05p)$, $p=0, 1, 2, 3, 4$, and so on, by numerically approximating the integral

$$N(t;r)=\int_0^{2\pi}\int_0^{\pi}|B_r(r,\theta,\lambda,t)|r^2\sin\theta\,d\theta\,d\lambda \qquad (2)$$

from values of B_r synthesised on a 10° by 10° zenographic θ (co-latitude) and λ (longitude) grid. (Here, r, θ, λ are spherical polar coordinates, t denotes time and B_r the radial component of **B**.) For each pair we have also calculated the secular change in N, namely

$$\Delta N(t_{11}-t_{10};r)=N(t_{11};r)-N(t_{10};r). \qquad (3)$$

The effective vanishing of ΔN at $r=r_c$ provides the theoretical basis of Hide's method for estimating r_c (refs 1, 6).

The computed values of B_r and hence of N and ΔN will depend on n^*, the maximum degree and order of terms of internal origin included in the spherical harmonic expansion, so

0.85	29.6	29.3	31.0		−339	+559		
0.80	31.7	31.3	33.7		−1200	−122		
0.75	34.2	33.6	37.0			−1200		

See equations (2) (3). Based on the spherical harmonic models (a), (b), (c) and (d) in terms of which Smith, Davis and Jones[2] analysed Pioneer 10 and Pioneer 11 observations of Jupiter's magnetic field for epochs December 1973 and December 1974.

we have calculated N for $n^*=2$ and $n^*=3$. (We omitted the most highly truncated case of all, $n^*=1$, because both N and ΔN then vary as r_s/r and r_c is indeterminate.) We also investigated the effect of omitting the external contribution to B_r, and found that this made negligible changes to the values of N and ΔN. Table 1 lists the mean value of N and the difference ΔN for each pair of models at $r=r_s(1-0.05p)$, with the integer p increasing from zero to at least two steps beyond the point at which ΔN changes sign. The values of N from the various models evidently agree well, even for the smallest values of r, but the values of ΔN are much more varied, and even at $r=r_s$ there is little agreement between the models. Nevertheless, not only do all the models show a change of sign of ΔN for both $n^*=2$ and $n^*=3$, but all of these sign changes occur over a surprisingly small range of r_c, between $0.6r_s$ and $1.0r_s$.

If, by taking $n^*=2$, only the dipole and quadrupole terms are included, the four models give $r_c=0.60r_s$, $0.82r_s$, $0.76r_s$ and $0.70r_s$ (see Table 1), the mean of which, $0.72r_s$, lies within the range of recent estimates of the radius r_m of Jupiter's metallic core, $0.7r_s$ to $0.8r_s$ (see above). When, in addition to the dipole and quadrupole terms, the less reliable octupole contribution is included (by taking $n^*=3$), only the first three models can be used. These give $r_c=0.88r_s$, $0.81r_s$ and $0.99r_s$ respectively, mean value $0.89r_s$, corresponding to levels well above the metallic core. (These estimates of r_c should also be compared with the white noise level $0.54r_s$ and the terrestrial analogue level $0.69r_s$, as determined by Elphic and Russell on the basis of considerations of the n-dependence of the quantity

$$(n+1)\left(\frac{r_s}{r}\right)^{2n+4}\sum_{m=0}^{n}[(g_n^m)^2+(h_n^m)^2] \qquad (4)$$

where g_n^m and h_n^m are the usual spherical harmonic coefficients of order m and degree n ref. 8).)

It is surprising that the new method[1], when applied to models based on data that are so poorly distributed in space and (more importantly) time, should give any value of r_c/r_s at all, let alone values which are both plausible and fairly consistent. While the present results must be regarded as very preliminary, they at least suggest that the method is appropriate and practical for the investigation of the interiors of planets with magnetic fields. It might be possible fairly soon to obtain better estimates of r_c for Jupiter by combining the Pioneer 10 and Pioneer 11 data with new data from Voyager 1 and Voyager 2, and it might also be possible to use the Pioneer and Voyager measurements of the magnetic field of Saturn to obtain a rough estimate of the radius of the electrically conducting fluid core of that planet.

A relationship between solar activity and planetary albedos

WE have observed a significant anti-correlation between solar activity and the brightnesses of two Solar System objects. Both the planet Neptune and Saturn's satellite Titan increased in brightness by several per cent between 1972 and 1976[1] and subsequently became fainter by comparable amounts[2]. This period corresponds to the decline of solar activity at the end of solar cycle 20 (1972–76), followed by the rapid increase of activity at the beginning of cycle 21. Solar minimum and the maximum observed brightness of Titan and Neptune both occurred in 1976. (The maximum of cycle 21 is forecast for late 1979 or early 1980, with a sunspot number ~150[3].) We hypothesise that what we have observed are changes in planetary albedos induced by solar activity. Such changes may have an important bearing on the energy balances of the outer planets and their satellites.

The observed solar–planetary relationship is shown in Fig. 1*a* for Titan and Fig. 1*b* for Neptune. Two measures of solar activity were chosen from the several available in the literature: the commonly used Zürich sunspot number, R_z, and an *ad hoc* index, F, the number of observed flares per month of importance 1 or greater. They are shown on the right-hand ordinate scales. The left-hand scales give the brightnesses of Titan and Neptune in the blue (b) and yellow (y) spectral regions in units of stellar magnitudes. The range of brightness variation was ~0.08 mag for Titan and 0.03 mag for Neptune, while the range of sunspot number was 0–130.

Figure 1 shows that there are usually two data points per observing season; they represent the mean magnitudes obtained from observations on a number of nights, typically 5–10, preceding and following opposition. The observations are normalised to zero solar phase angle and to mean heliocentric distances of 9.539 and 30.071 AU for Titan and Neptune, respectively. During a single season, each object is measured differentially with respect to two nearby comparison stars whose colour approximates that of the Sun, and subsequent observations determine the relative magnitudes of the comparison stars. A detailed error budget for these observations and a rationale for the method by which they were obtained have been given elsewhere[1].

0028-0836/79/270043—03$01.00

© Macmillan Journals Ltd 1979

All the plotted quantities in Fig. 1 are obviously highly correlated with one another. The correlation of the *y* magnitudes of both objects with the sunspot number is significant at better than the 99% level, while the *b* magnitude correlations with sunspot number are significant at the 95% level. The correlations of magnitude with the flare index are significant at the ~90% level.

Many directly observed indicators of solar activity (such as 10.7 cm radio flux, coronal line spectrum, number of flares and prominences), as well as solar–terrestrial effects (such as geomagnetic field strength, and cosmic ray flux at the Earth) rise and fall during the 11-yr sunspot cycle, just as the sunspot number does, and would therefore also show a good statistical correlation with the magnitudes of Titan and Neptune. We chose to illustrate the correlation using the sunspot number and flare index.

The observations were made using the 0.5-m reflecting telescope of the Lowell Observatory, a photoelectric photometer equipped with a thermoelectrically cooled EMI 6256 photomultiplier, pulse-counting electronics, and DEC PDP-11 computer. There were no changes in the auxiliary instrumentation during the entire course of the programme. Observations were obtained through two intermediate-band interference filters of the Strömgren photometric system; *y* at 551 nm (HPBW = 23 nm) and *b* at 472 nm (HPBW = 20 nm). All magnitudes are expressed on the natural instrumental scale (that is, not transformed to the 'standard' Strömgren scale) to preserve their inherent high internal accuracy which derived from an extremely stable instrumental configuration.

The change in aspect of a Solar System body as seen from the Earth can cause photometric variations. In the present case these seem to be ruled out. The maximum apparent inclination of Titan's orbital plane (27° with respect to the ecliptic) occurred in May 1974, while maximum brightness was reached in early 1976 when the inclination was 22°. Assuming rough symmetry of the northern and southern hemispheres of Titan (a plausible assumption in view of Titan's thick atmosphere), a seasonal variation would have a period of 15 yr and an amplitude of ~0.2 mag, based on the variations observed by us during one-fifth of a Saturn year. Historically[4], variations of Titan do not exceed 0.1 mag. Moreover, many configurations of surface markings, if any should be visible through the atmosphere, would lead to substantial variations during Titan's 16-d orbital period. These variations, if they occur at all, are very small (<1%)[5]. The case against seasonal effects on Neptune is even stronger. Since 1972, both the change in aspect as seen from the Earth and the fractional change in solar irradiation were completely negligible.

How the 'solar constant' changes over long periods remains uncertain: the best available Nimbus satellite data suggest that

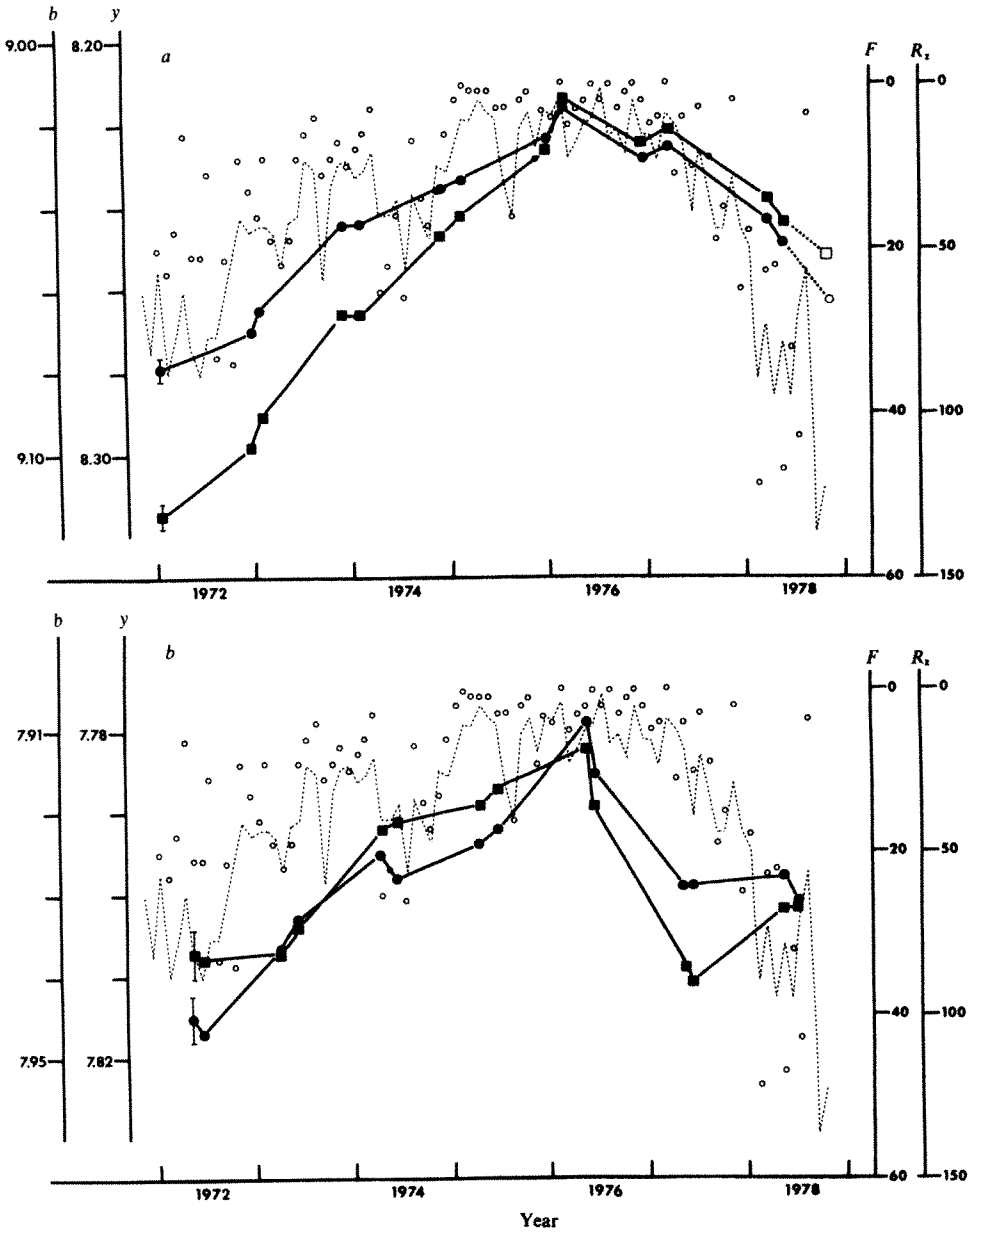

Fig. 1 *a*, Titan and *b*, Neptune. Planetary brightness as a function of time in units of stellar magnitudes (0.01 mag ~1%) plotted with brightness increasing upward. Note that the magnitude scales for *a* and *b* are not the same. Typical error bars are shown on the left-most data points. The monthly mean sunspot number R_z (dashed line), and the 'flare index', *F* (○), are plotted increasing downward. The solar data are from the *IAU Quarterly Bulletin on Solar Activity* and *Solar-Geophysical Data*. The flare index was made by counting the number of separate flares per month of importance ⩾1 tabulated in these publications. ●, yellow values; ■, blue values.

any changes on a time scale of months are smaller than ~0.2%[7], far too small to account for the effect we have observed.

The apparent synchronisation of solar activity with the observed variations of two separate and independent planetary bodies led us to hypothesise that one or more components of the solar output which vary during the solar cycle could cause changes in the albedos of planets and satellites.

While the thermal structure of Titan's atmosphere remains doubtful, its low albedo in the UV and visible regions implies, according to current models, the existence of a dust layer or photochemical 'smog'. Recent work has explored the possibility of chemical reactions in Titan's atmosphere intiated by cosmic rays, the 'Saturn wind', and the solar wind[8], as well as photochemical processes leading to the conversion of the abundant CH_4 molecule to heavier hydrocarbons in the atmospheres of the major planets[9]. Such reactions, if they occur, must surely be sensitive to variations of the incident particle or radiative flux; and, therefore, variations in atmospheric composition and structure could also occur, leading to variations in albedo.

Variations of the solar radiative flux below 300 nm during a solar cycle, according to the best best available data, range from ~1% at 300 nm to several orders of magnitude below 2 nm[6]. The solar wind and interplanetary magnetic field have recently been sampled in the outer Solar System and have been found to vary in complex ways during the solar cycle[10,11].

However, to our knowledge, no studies have been made to consider the consequences of variations of the solar radiative and particle output on planetary atmospheres; and therefore our meagre interpretation of the observed planetary brightness variations is rather speculative. We emphasise that the atmospheric dynamics and chemistry of the major planets and Titan are incredibly complicated and much theoretical work remains to be done before an adequate interpretation will be possible.

In addition to the recent data shown on Fig. 1 we have analysed[12] the more extensive but less accurate Lowell Observatory photoelectric photometry of Uranus and Neptune dating from 1953 to 1966[13,14] to look for evidence of transient effects such as a planetary response to solar flares, for short-term (month-to-month) correlations with daily and mean monthly sunspot numbers, and for a periodicity in observed brightness at or near the solar rotation frequency. Using correlation techniques, we have looked for time-delayed effects lagging by a few hours (corresponding to propagation at the speed of light), by a few weeks to several months (corresponding to the average speed of the solar wind), and by longer intervals up to one year. None has yet been found at a level of 0.003 mag or greater for Neptune or Uranus, which suggests that transient events may be relatively unimportant.

Thus it seems more likely that it is the long-term envelope of solar activity that drives planetary albedo changes and that these changes derive from relatively slow structural and chemical changes in planetary atmospheres.

This research has been supported since 1972 by the Atmospheric Sciences Program of the NSF.

Drag reduction in fibre suspensions: transitional behaviour due to fibre degradation

IT is known that the addition of small amounts of certain polymers to a fluid can produce spectacular reductions in turbulent friction[1,2]. It is also possible to reduce friction by suspending macroscopic fibres in a fluid[3]. Superficially there are many similarities between the two effects but they are believed to involve different mechanisms because, for example, using polymers and fibres together can produce much larger reductions in drag than would be the case with either additive on its own[4]. We report here measurements of turbulent velocities in a fibre suspension, using laser–Doppler anemometry. We found that the effect of fibres on turbulent structure was not the same as that of polymers. However, when the fibre was degraded by passing it through the system several times, there was a transition to the type of structural change found in polymer solutions.

The fibres used were chrysotile asbestos and are known to be very effective drag reducers. A nominal fibre concentration of 300 p.p.m. by weight was used throughout. Following the usual practice, the fibres were dispersed in 0.5% aqueous solution of Aerosol OT.

A 'blow-down' flow rig was used to minimise degradation of the fibres. Suspensions were prepared in a header tank and then allowed to flow under gravity into a pressure tank. Air pressure was used to propel the suspensions through a horizontal pipe of 2 cm nominal bore and then through a return line to the header tank. Flow rates were controlled by a constant-flow valve. The actual flow rate was determined by timing the change in levels on a sight-glass in the pressure tank. The test section of the pipe was

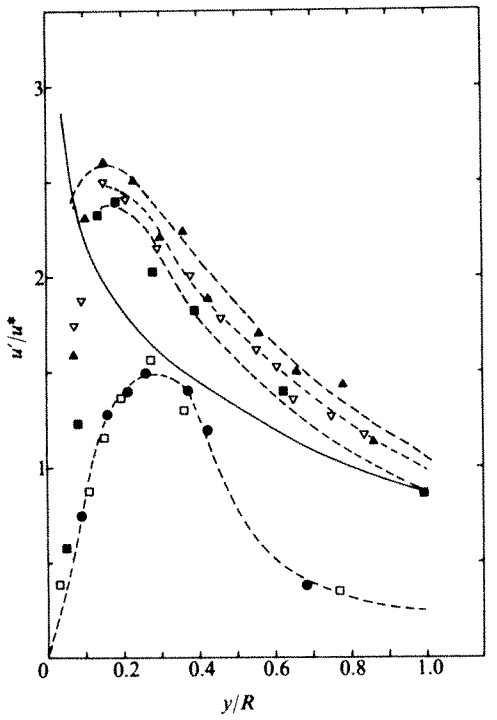

Fig. 2 Streamwise turbulent intensity profiles in a 300 p.p.m. asbestos fibre suspension at various levels of drag reduction, for $R_e = 9 \times 10^3$: continuous line denotes results for water. ● Run 1, DR = 63%. □ Run 2, DR = 63%. ▲ Run 4, DR = 44%. ▽ Run 10, DR = 22%. ■ Run 17, DR = 17%.

situated at 154 diameters from the inlet to ensure well developed flow. Pressure drops were measured using pressure taps and a liquid-in-glass manometer.

Streamwise velocity profiles were measured over the cross-section of the pipe, using a laser–Doppler anemometer (LDA). The optical and signal-processing arrangements were as reported previously[5].

An experimental 'run' consisted of one pass of the whole amount of working fluid through the apparatus at a fixed Reynolds number. Further 'runs' were further passes of the same fluid at the same Reynolds number. Experimental results were always taken in steady conditions, avoiding the beginning and end of each run. Reynolds numbers were calculated from the pipe diameter, the bulk mean velocity and the kinematic viscosity of water.

These particular fibres are known to be susceptible to degradation under shear. Our results confirmed this and showed a decline in drag-reducing effectiveness with increasing run number. We decided to make a virtue of necessity and used this as an experimental parameter. The results were interesting.

Figure 1 shows mean velocity U^+ (scaled) plotted against distance from the pipe wall y^+ (scaled), in the usual 'wall-region' coordinates, for a Reynolds number of 9×10^3. The amount of drag reduction appears as a parameter. It can be seen that the first two runs gave a drag reduction of 63% and that the corresponding mean velocity profiles lay beyond the Virk asymptote for polymer solutions. In contrast, the results for later runs in the degraded suspensions were in the polymeric regime. Like results for polymers, they show a trend to the newtonian result, as the amount of drag reduction decreases.

Figure 2 shows the r.m.s. velocity u' (divided by the friction velocity u^*) plotted against distance from the wall y (divided by the pipe radius R). Here the differences between high and low drag reduction are seen to be no longer a matter of degree only. Runs 1 and 2 showed a marked suppression of the streamwise fluctuating velocity, compared with the newtonian result. However, in later runs the intensity over most of the cross-section was increased above the newtonian result. Again, these results in later runs were similar to those previously found in polymer solutions[1].

This behaviour has also been found in further experiments at a higher Reynolds number, 1.4×10^4. Thus it seems that we are observing a transition between two different drag-reduction mechanisms. When the fibre is at maximum effectiveness, it behaves quite differently from polymers which produce comparable amounts of drag reduction. In particular, it suppresses the streamwise turbulence. After degradation, when the fibre is (presumably) smaller it seems to behave rather like a polymer of the same effectiveness. In particular, it enhances the streamwise turbulence.

It might be tempting to conclude from Figs 1 and 2 that the undegraded fibres reduce drag by suppressing turbulence and making the flow 'more laminar'. Such a conclusion would be wrong. In our more recent experiments we have used a second LDA to measure the spanwise turbulent intensity. During runs 1 and 2, the spanwise turbulent intensity was actually larger than in water alone. In the later runs, the spanwise intensity was less than that for water alone. Rudd has previously reported[6] reduced spanwise intensities in polymer solutions.

We already know that the turbulent structure is changed during drag reduction in polymer solutions[1,6]. Our present results indicate that in undegraded fibre suspensions the change in turbulent structure during drag reduction is of a different kind. This effect was previously predicted on theoretical grounds[7].

We thank Turner Brothers Asbestos Co. Ltd for drag-reducing chrysotile asbestos suspensions.

Ferromagnetism in ancient copper-based coinage

WHEN extensive forgery of silver coinage has taken place in the past, a small permanent magnet was a well known technique for distinguishing between counterfeit nickel and genuine silver coins. The accidental discovery of ferromagnetism in undisputably genuine ancient Kushan copper coins by Nisbet during a routine check with a permanent magnet was, however, totally unexpected. Although we have found very few coins possessed a magnetic moment sufficiently large for the coin to be lifted by the permanent magnet, subsequent examination has revealed that several coins possess a spontaneous remanence magnetisation which can be detected with a simple deflection magnetometer. Quantitative measurements of the room temperature magnetisation have been performed in fields up to 5×10^5 A m^{-1} using a Faraday balance magnetometer. To our knowledge they form the first systematic study of the magnetic properties of ancient coinage.

The magnetometer sensitivity was about 10^{-2} J T^{-1} kg^{-1} and the Pauli paramagnetism of the conduction electrons could not be detected. As Fig. 1 shows, the magnetisation of an orichalcum semis of the Roman Emperor Tiberius remained below the noise level up to the maximum fields available. Similar null results

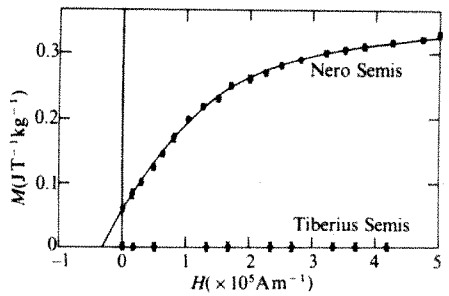

Fig. 1 Magnetisation as a function of field for two Roman orichalcum coins. The magnetisation of the Tiberius semis was at all times well below the instrumental sensitivity.

were obtained with modern bronze coinage, entirely consistent with the expected paramagnetic behaviour. In marked contrast, an orichalcum semis of the Emperor Nero (dated to 63–64 AD) not only showed significant remanence magnetisation but also a marked increase with increasing magnetising field. Although the susceptibility fell as the field was raised, no tendency towards saturation was observed. When the field was reduced, the remanence magnetisation returned to its initial value. The coercive field H_c, (that is, the reverse field required to reduce the magnetisation to zero) was found to be 3.2×10^4 A m^{-1} (400 Oe) and the remanence magnetisation M_r to be 5.5×10^{-2} J T^{-1} kg^{-1}.

Orichalcum, first analysed in 1798 by Klaproth[1], is an alloy of copper and zinc and is generally believed to have been produced by a cementation process, in which copper bars were heated in a crucible containing a zinc ore and charcoal[2]. Such an alloy should not possess a spontaneous magnetic moment. Recent analyses have shown, however, that some Roman orichalcum coins may contain up to 1% iron impurity[3], and with this in mind magnetisation measurements were performed on a series of coins exhibiting ferromagnetism which had been previously analysed by Thompson using spark emission spectroscopy.

Although neglected in secondary school teaching in the West, the Kushan Empire was the third of the great empires of antiquity controlling the caravan routes between Rome and Cathay. At its height it covered what is now Afghanistan, Pakistan, North-west India and Southern Russia.

Magnetisation measurements were made on 12 copper Kushan coins of known chemical composition. A typical magnetisation curve is shown in Fig. 2*a*. All coins showed ferromagnetic behaviour, and saturated in fields of about 1.5×10^5 A m^{-1} in marked contrast to the Roman orichalcum coin. The coercive field was low, having a mean value of 3.9×10^3 Am^{-1} (with a 1σ error of 1.2×10^3 A m^{-1}). Although both the shapes of the magnetisation curves and the values of the coercive fields were all very similar, two distinct groups of coins were identified. Coins of the late Kushan period (mid-third to mid-fourth century AD) displayed a very low saturation magnetisation M_s and remanence so small as to be undetectable with a deflection magnetometer. Coins produced during the period of great expansion of the Kushan Empire under Kanishka (second quarter of second century AD) showed saturation and remanence magnetisation two to three orders of magnitude greater than those of the late Kushan period. These remanence magnetisations were easily measured with a deflection magnetometer. The strong ferromagnetism was thus confined to coins of a restricted historical period.

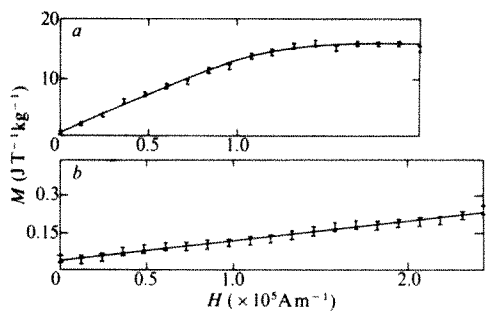

Fig. 2 *a*, Magnetisation curve for a copper drachm of Kanishka (Kushan Empire). Note the saturation, small remanence magnetisation and low coercive field. *b*, Magnetisation curve for a similar Kashmiri coin. Note the high coercive field, and lack of saturation.

In contrast, early Hindu copper coins from Kashmir, showed markedly different magnetisation curves. Nine coins whose dates ranged over a wide period were examined. All showed ferromagnetic behaviour but, as with the orichalcum coins, no saturation occurred up to the highest fields available (Fig. 2*c*). A large spread occurred in the coercive fields but all were significantly larger than that of the Kushan coinage. The mean value of 2.9×10^4 A m^{-1} (with 1σ error of 1.8×10^4 A m^{-1}) is nearly an order of magnitude greater than the mean value for Kushan coins and is comparable with that of the Roman orichalcum. No correlation has yet been established between strong ferromagnetism in the Kashmiri coins and the historical period.

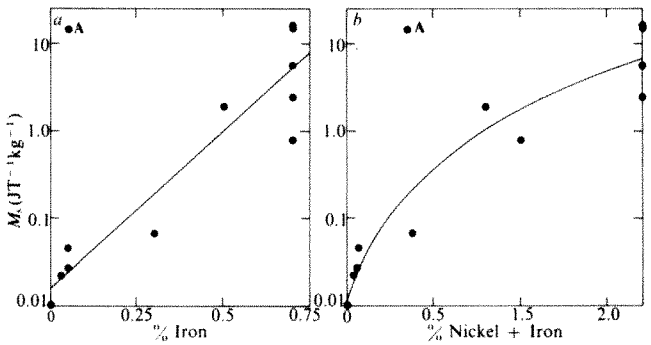

Fig. 3 *a*, Log-linear plot of saturation magnetisation versus iron content in Kushan coinage. The straight line is a least squares fit to the data. The point A was rejected in the fit on the grounds of unreliability of the analysis. *b*, Log-linear plot of M_s versus total iron and nickel content. The line is a guide for the eye.

A correlation does exist between concentration of iron and the saturation magnetisation M_s in the Kushan coinage. The chemical analyses show the lead, nickel and iron content of the Kanishka coins to be of the order of 1%, significantly above that of the late Kushan coins. Nickel, though ferromagnetic itself, forms a complete solid solution in copper and a 99% Cu–1% Ni alloy is not ferromagnetic at room temperature. However, iron is almost insoluble in copper and a dispersed-phase alloy of 99% Cu–1% Fe would have a magnetisation comparable with the largest values measured. Figure 3*a* shows a log-linear plot of M_s versus iron content. Clearly, the saturation magnetisation is directly related to the iron content. Fitting a straight line to the data by the least squares technique yielded a correlation coefficient of 0.94. However, a correlation still persisted when the total ferromagnetic impurity concentration (Fe + Ni) was plotted against M_s (Fig. 3*b*). As iron and nickel form a range of ferromagnetic alloys it is unclear what role the nickel plays and until more information on the structure of the material is available care should be exercised in interpreting these data. As yet it is unknown whether the iron is present as the element or as an oxide.

The ratio of saturation to remanence magnetisation (M_s/M_r) versus iron content is shown in Fig. 4. M_s/M_r is approximately the same for all the coins and there is no significant dependence on iron (or nickel) content.

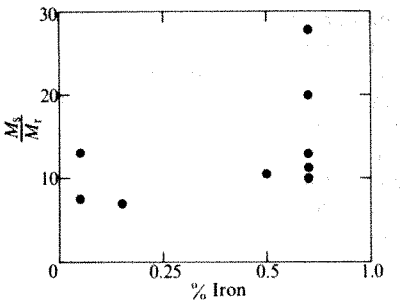

Fig. 4 Ratio of saturation to remanence magnetisation versus iron content in Kushan coinage. (Note that this is a linear plot, unlike Fig. 3.)

We may summarise the results of these initial investigations as follows. (1) Ferromagnetism in ancient coinage arises from the presence of ferromagnetic impurity in the copper-based matrix. (2) The occurrence of ferromagnetism may well have archaeological significance. Very high values of saturation magnetisation in the Kushan coinage are confined to a relatively short period during which time the empire was rapidly expanding. There is some numismatic and historical evidence to suggest that these coins may have been minted from freshly mined copper. (3) The magnetic characteristics (for example, the coercive field) are very different in the otherwise similar Kushan and Kashmiri coins. The magnetic properties may well give a clue to the origin of the ore. High coercive field and high saturation field could be strong indicators of re-usage of old coinage in the minting process. (4) Within a factor of three, the ratio of saturation to remanence magnetisation of the Kushan coinage is constant. Thus M_r can be used to give an order of magnitude estimate of M_s. As M_r can be measured with a simple deflection magnetomerer, useful physical measurements can be performed on confined collections such as that in the British Museum.

We thank J. D. F. Nisbet for information about his accidental discovery, and Professor F. C. Thompson, for performing the chemical analyses on the coins studied. I.B.M. acknowledges a maintenance grant from the SRC.

Confirmation of the Suess wiggles: 3200–3700 BC

USING dendrochronologically dated tree rings de Vries[1] showed that the atmospheric ^{14}C concentration has not been entirely constant during the past few hundred years. By extending the North American bristlecone pine tree-ring chronology[2] to nearly 8,000 yr ago, several radiocarbon laboratories succeeded in measuring deviations in the ^{14}C concentration from the mid-nineteenth century natural ^{14}C level to a maximum of about 10% around 4000 BC (refs 3–7). Superimposed on this general trend, Suess drew with 'cosmic schwung', medium-term variations through his data. These so-called 'wiggles' should correspond with variations in the abundance of radiocarbon in atmospheric carbon dioxide on a time scale between one decade and a few centuries. The resulting irregular shape of Suess' calibration curve has been questioned during the past few years[8,9]. The overall result, however, is that no generally accepted ^{14}C calibration curve is yet available. It would be most convenient to measure ^{14}C concentrations in single tree rings with much higher precision than the usual 4–6‰. For this, however, much larger samples are required than are available from the bristlecone pine tree. An excellent opportunity was presented by the sub-fossil oak trunks discovered in the river valley sediments of southern Germany[9]; our measurements of these trunks are reported here.

Our first measurements were carried out on a 500-yr section of the 1,235-yr floating South German Neolithic tree-ring chronology. The section used was derived from well preserved sub-fossil oaks, which grew along the River Danube (49°25'N, 10°5'E). To avoid recycling due to soil CO_2 during an early stage of tree growth no rings from near the centre of a log were analysed. Because recent results[11] have shown that if year to year ^{14}C variations are small then radial movement of ^{14}C across ring boundaries in an oak is negligible, the measured ^{14}C concentration in a single tree ring nicely represents the atmospheric ^{14}C concentration in the growth season of a tree ring. Although wood, after pretreatment with successive solutions of 4% hydrochloric acid, 4% sodium hydroxide and 4% hydrochloric acid again (AAA) probably do not exactly originate from exactly the same time of the year as the cellulose fraction, the AAA pretreatment seems to be acceptable for monitoring past ^{14}C levels[11]. The final sample prepared for analysis was 50–55 l of CO_2 gas at STP. The special high-precision proportional gas counting system will be described elsewhere[12].

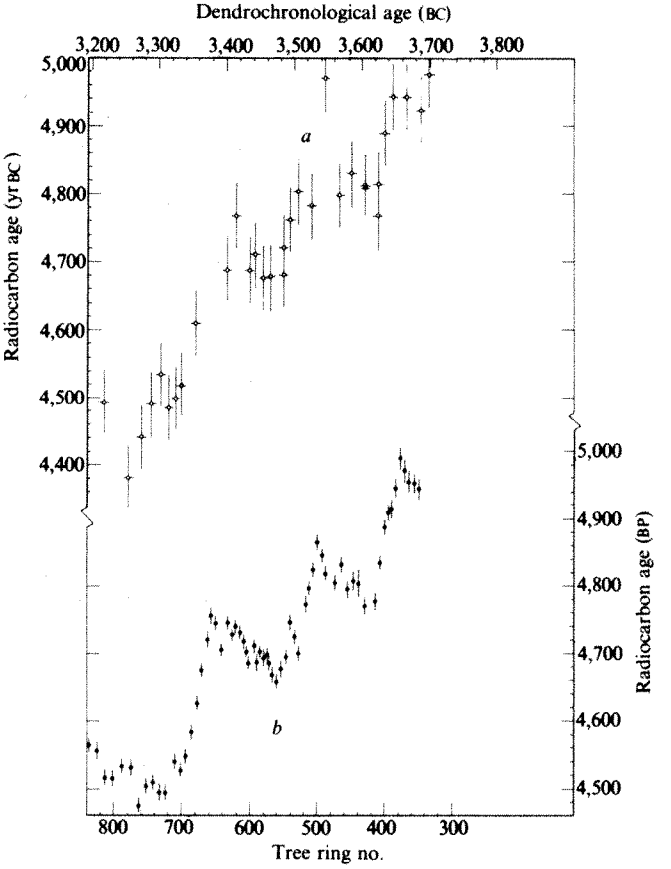

Fig. 1 ^{14}C analyses on dendrochronologically dated wood (*b*). The relation between radiocarbon age and the tree-ring number from the floating South German Neolithic master chronology. For comparison, *a* shows the bristlecone dates, corrected to the proper standard activity (0.95 × NBS-oxalic acid)[6].

0028-0836/79/270048—02$01.00
© Macmillan Journals Ltd 1979

The results are presented as conventional ^{14}C ages in Fig. 1*b*, related to the tree-ring number from the floating South German Neolithic master chronology.

Figure 1 confirms quantitatively the existence of pronounced wiggles between the thirty-third and thirty-seventh centuries BC. The fact that the upward slopes from right to left are less steep than the downward slopes suggests that we are faced with secular variations in the atmospheric ^{14}C level consisting of relatively fast rises followed by a restoration of the stationary state. This conclusion is supported by the rather regular periodic behaviour of the 'wiggles' with a period of approximately 180 yr. Calculations based on geophysical and geochemical models might provide a more definite answer to the question of the origin of the variations.

A comparison with the bristlecone dates of Suess[6] corrected to the proper standard activity (0.95 NBS oxalic acid), which makes the dates approximately 50 yr older than listed, leads to the absolute time scale for our floating chronology (Fig. 1*a*). The South German Neolithic master chronology seems to start at 4035 ± 3 BC. Wiggle matching Suess' results on the German material with the bristlecone sequence gave a comparable result (4057 BC)[10,13].

For archaeological samples which are 'short lived' (of the order of a few tens of years) these medium-term variations add an extra uncertainty to the purely statistical error of a ^{14}C-age determination.

Sulphur uptake from the atmosphere by forest and farmland

MEASUREMENTS of sulphur uptake by plants are needed to aid our understanding of the long-range transport of sulphur dioxide and the role of sulphur uptake in acidification and the nutrient balance of forest ecosystems[1]. The traditional profile method of analysing sulphur uptake has proved inadequate for forest measurements because the vertical concentration gradients above forests are small and difficult to measure with current techniques[2]; the best estimates available are based on extrapolation of measurements from individual shoots to the whole forest[3]. We report here the first direct measurements of the uptake of sulphur from the atmosphere by a forest in the absence of precipitation (that is, dry deposition). These measurements were possible because of the development of a fast response sulphur detector which allowed, for the first time, use of the eddy correlation method[4] for sulphur uptake measurements. The sulphur uptake ranged from 0–0.1 $\mu g\ m^{-2}\ s^{-1}$ (as SO_2) for atmospheric sulphur concentrations up to 35 $\mu g\ m^{-3}$ (expressed as SO_2). On average, ~75% of the atmospheric sulphur was in gaseous form. These uptake rates support those derived from use of the recent hypothesis that sulphur dioxide uptake by vegetation takes place through the stomatal opening for a dry canopy[3]. Some measurements of dry uptake of sulphur over farmland were also made and are in close agreement with published measurements made over similar surfaces using the profile and other methods.

The eddy correlation method can give a direct measurement of the vertical flux of a constituent within the air. If the concentration of the constituent is fairly constant (that is, storage is negligible), the vertical flux within the atmosphere is equal to the uptake rate at the underlying surface. At a fixed point above the surface, continuous fast response measurements are made of the vertical wind velocity, w, and the concentration (ambient density) of the constituent, c. The vertical flux of the constituent, F, is given by the covariance $F = \overline{wc}$ where the overbar indicates the time average. We assume that the time averaged vertical velocity is zero, $\bar{w} = 0$, (ref. 5), therefore $F = \overline{w'c'}$ where the prime indicates the instantaneous departure from the long-term mean. This uptake of the constituent from the atmosphere is conveniently expressed in terms of a deposition velocity, v, and the air concentration of the constituent, c, by an equation $F = vc$ (refs 1–3, 6).

A Gill propeller anemometer was used to measure the vertical velocity. While the response time τ of a Gill propeller (that time to reach $1 - 1/e$ of the final speed following a step change in wind speed) depends on mean wind speed U, a response length $L = U\tau$ should depend only on the turbulent intensity and L was estimated to be 2 and 3 m for the Crowthorne (forest) and Blewbury (farmland) measurements respectively[7,8]. The flame photometric sulphur detector[9], with a 4-m gas inlet tube, had a response time measured in the field of 0.3 s. This response time was determined mainly by the inlet tube. There was also a time delay of 1.8 s in the gas-inlet system of the sulphur detector. This was corrected for in the covariance calculation by displacing digital records from the sensors by this time interval. Ambient air temperature was measured using a fast-response bead thermistor to determine the sensible heat flux. The sensors were sampled at 5 Hz by a digital computer for the covariance calculations. No low frequency filter was used in the system but fluxes were computed for individual 10- or 12-min periods.

The flux values were corrected[7,8] due to inadequate speed of response of the anemometer and to smoothing from the sulphur detector inlet system to allow for flux losses. The corrections were 10 and 20% for the Crowthorne and Blewbury data respectively. Low frequency flux losses, probably of the order of 5–20% (ref. 10) have not been corrected for in the flux estimates. The ratio of height of sampling to length of uniform fetch upwind of the sensors was such that even in the worst case the flux should be 90%, adjusted to the underlying forest surface. Adjustment was often complete[11].

Measured non-zero values of $\bar{w}$ indicated slight misalignment of the vertical propeller amounting to ~1°. This misalignment introduces an error into the mass flux measurement of the order of 4% per degree[5,12]. Considering these factors we estimate the absolute accuracy of the average flux measurements to be of the order of ±50%. The short sample period will cause a scatter in individual flux values of ±25% (refs 13, 14).

Measurements in the field suggest that the standard deviation in a single 10-min flux measurement due to instrument noise alone would be ±0.02 to ±0.03 $\mu g\ m^{-2}\ s^{-1}$ and that the standard error in average values from hours of observations as in Table 1 from instrument noise alone would be perhaps ±0.006 $\mu g\ m^{-2}\ s^{-1}$. A description of the full system along with a complete analysis of the data will be published elsewhere.

Measurements were made at two sites (see legend to Table 1). At the farmland site the equipment was located at the boundary between two fields. In an easterly wind the fetch was entirely over a grass crop, and in a westerly wind, over a pea crop. Table 1 shows the average uptake rate for each range of concentration and is composed from all the individual flux measurements made in the concentration range. The data suggest a deposition

† Farmland: Blewbury, Berkshire. Easterly fetch; Italian rye grass 75 cm; westerly fetch, peas 40 cm. Flux measurement 4 m above soil surface. Measurements are for six days between 21 June and 5 July 1977.

velocity of about 0.2 $cm\ s^{-1}$ for these forest measurements and about 0.6 $cm\ s^{-1}$ for the farmland measurements. All measurements were made in a turbulent atmosphere.

The sulphur detector responds to gaseous and particulate compounds. Particulate sulphur contributes only a fraction of the fluxes reported here, as the sulphate concentration at the field sites, assumed to be similar to that measured at Harwell, was only 20% of the total sulphur at the higher concentrations and the deposition velocity for small particles such as sulphate is much smaller than, or comparable with, that for sulphur dioxide[2,15].

Garland[2] summarises measurements of sulphur dioxide deposition over grass, crops and bare soil made by the profile and radioactive methods that give deposition velocities in the range 0.3–1.2 $cm\ s^{-1}$ with a median value 0.8 $cm\ s^{-1}$, in close agreement with that measured by the eddy correlation method here. Profile measurements in a forest[2] suggested an upper limit of the deposition velocity of 2 $cm\ s^{-1}$. Estimates based on measurements of individual shoots and extrapolation suggest a deposition velocity varying from a daytime maximum value of 0.6 $cm\ s^{-1}$ in the morning to 0.2 $cm\ s^{-1}$ in late afternoon to a night-time value of 0.1 $cm\ s^{-1}$, depending on stomatal resistance (closure) for a dry forest canopy[3]. The measurements presented here for the higher sulphur concentrations suggest a similar low deposition velocity for sulphur on the forest canopy during the afternoon. (We found no evidence of a diurnal variation in surface resistance during the period of our measurements.) Forest measurements were made when the new growth on the forest was just emerging and most of the exposed needles would have been from previous year's growth and are known to display lower uptake rates[3]. Furthermore, the sensible heat flux from the forest was frequently about 50% of the global total incoming solar radiation. This indicates that little evapotranspiration was taking place. The stomatal resistance to gaseous transfer would most probably be high in these conditions. Indeed, stomatal resistance is generally higher during the afternoon[3,16], and the measurements presented here may be for a forest in conditions of maximum resistance to sulphur uptake. The observed fluxes over forest and farmland can be entirely accounted for in terms of sulphur dioxide deposition. However this does not preclude a large deposition velocity for particulate sulphur.

The dry deposition to a dry forest canopy at a mean sulphur dioxide concentration of 10 $\mu g\ m^{-3}$, typical of many rural locations, would be perhaps 2–3 kg sulphur $ha^{-1}\ yr^{-1}$, if the representative deposition velocity is as low as that measured here. This is a significant fraction of the estimated total sulphur deposition in English and Scottish upland sites of 10–20 kg sulphur $ha^{-1}\ yr^{-1}$ (ref. 1). If as suggested[3] gaseous and particulate uptake onto a wet canopy could account for a much larger fraction of the total deposition, then measurements with the method presented here can resolve this question.

We thank L. C. Cox for help with the field work, A. Hadjitofi for developing the sulphur detector, M. M. Davies for programming the computer, C. Healy and Miss J. B. Tarrant for the sulphate analyses, the Director of the Road Research Laboratory and the Manager of Churn Estates farm for access to field sites. I.E.G. thanks the Nuffield Foundation for a Travelling Fellowship and Dr A. C. Chamberlain for his help during the visit. The work was supported by the Department of the Environment.

Magnetic measurements used to assess sediment influx at Llyn Goddionduon

THE preliminary results of an attempt to estimate sediment influx in a small upland lake using magnetic susceptibility measurements on whole unextruded sediment cores obtained from a grid covering almost the whole area of open water are reported here. The susceptibility variations, reinforced by a wider range of magnetic measurements on individual samples, provide a basis for core correlation over the whole lake. The speed with which such studies can be accomplished makes possible a much more secure empirical basis for calculations of total sediment input versus time than do conventional methods of core correlation and analysis.

Increasing attention is being devoted to using lake sediments as sources of information about changing ecological processes in the recent past[1,2]. In many cases a large proportion of the lake sediment can be shown to have been derived from the lake watershed. The palaeoenvironmental record may, therefore, often be interpreted largely in terms of changes in the terrestrial ecosystems draining into the lake[3,4]. A prerequisite of fully quantitative studies designed to relate the sedimentary record in the lake to changing material output from its catchment is some procedure for calculating or estimating sediment influx to the whole lake for defined time intervals. Without this procedure all calculations of influx may be biased by the unrepresentative nature of a small number of coring sites.

Empirical attempts to overcome this problem[5] are limited largely by the time-consuming nature of the techniques normally available for core correlation in the absence of synchronous visual stratigraphic markers. Theoretical models developed to allow calculation of total sediment input from a single central core[6], though valuable are unconvincing in view of the numerous unverified assumptions on which they depend.

Thompson *et al.*[7] have shown that magnetic susceptibility measurements of whole, unextruded sediment cores can provide a rapid method of core correlation. The technique leaves the material unaltered, precludes no subsequent study of any kind and can be followed up by a range of related simple, rapid and non-destructive magnetic measurements[8] which often indicate sediment source[9,10] and are directly related to changes in human activity[7,8,11].

Llyn Goddionduon (Fig. 1*a*) lies 244 m above OD in the Gwydyr Forest area of North Wales, ~4 km north-west of Bettws y Coed (G.R. SH 753 586). It covers 6.2 hectares and receives drainage from a catchment of ~25 hectares. Maximum water depth is 6 m, in a small 'trench' occupying <5% of the area of the lake bed. Of the present sediment surface, 50% is between 0.75 m and 4 m deep. A small mire ~0.6 hectares in extent at the southern, outflow, end of the lake represents overgrowth of peat lying partly on marginal lake sediments. Some 25% of the lake is colonised by macrophytes among which *Schoenoplectus lacustris, Phragmites communis, Eleocharis palustris, Nymphaea alba, Potamogeton natans* and *Equisetum fluviatile* are the most abundant species[12].

An accurately surveyed grid of 130 minicores[13] was sampled during a 2-week period in July 1977, using a research team varying from five to nine people. Cores were taken at 20 m × 20 m intersections. Where impenetrable substrate precluded this, intermediate cores were taken. In the small trench area an extremely high density of sampling was achieved (27 cores in 950 m^2). Whole core susceptibility measurements were carried out on all cores during the same period of field work using a low-field susceptibility bridge[14] temporarily installed in the Drapers Field Study Centre 3.5 km from the lake. Volume susceptibility (κ) versus depth graph plots were produced

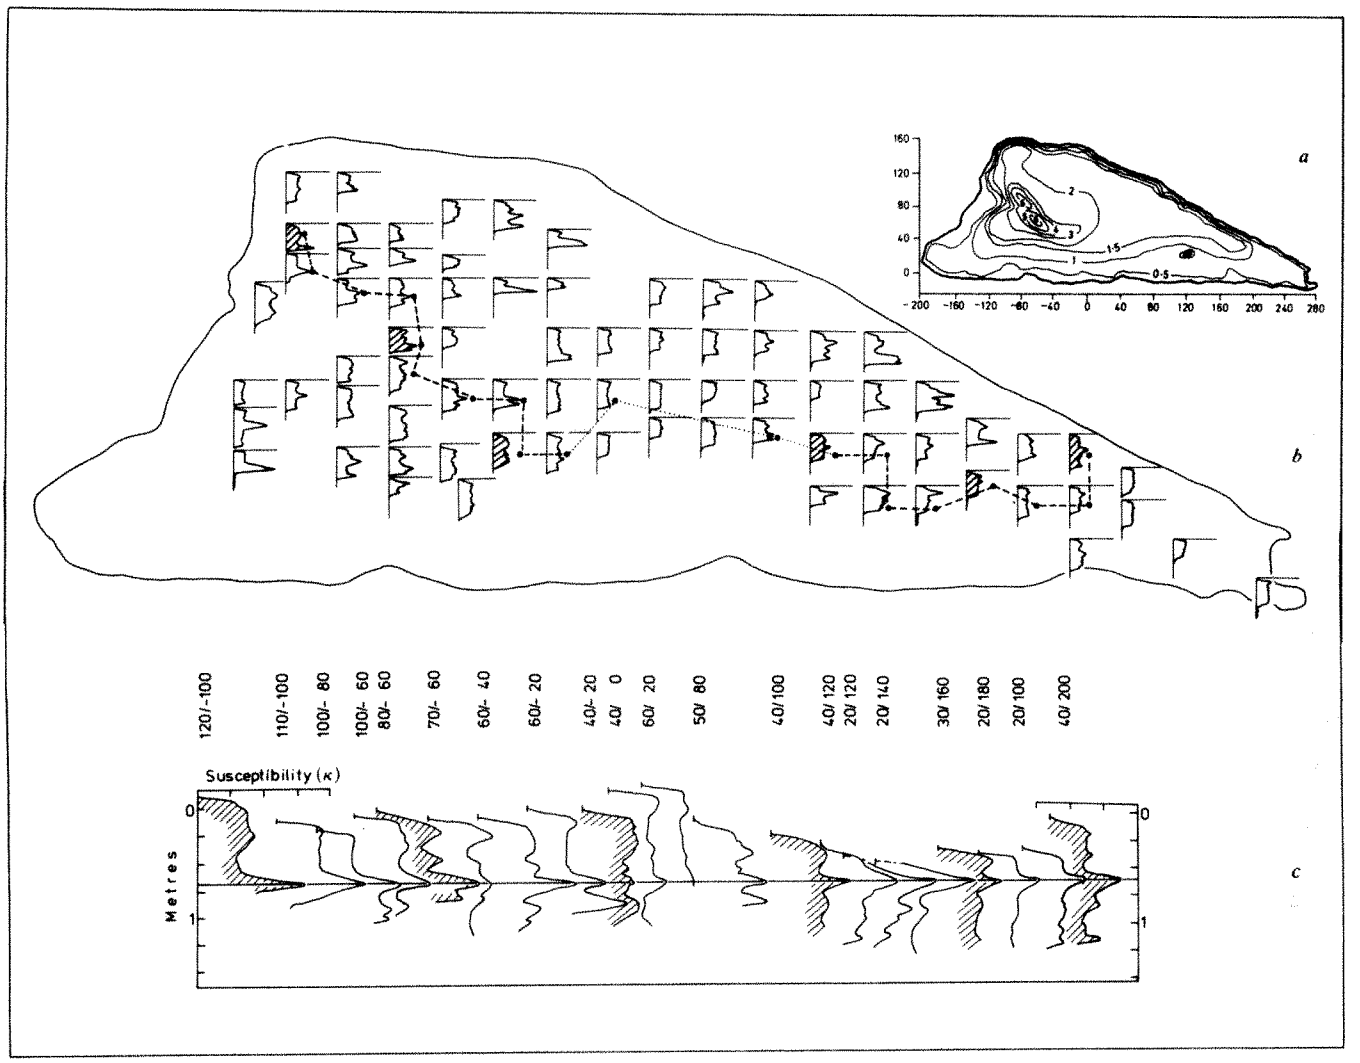

Fig. 1 Llyn Goddionduon: *a*, Bathymetric map and coring grid coordinates; *b*, whole-core susceptibility traces from the main coring grid. The 'tie-line' joins the cores from which the linked and correlated traces shown below in *c* were obtained. The cores for which single sample χ, SIRM and χ/SIRM ratios are plotted in Fig. 2 are identified by shaded traces.

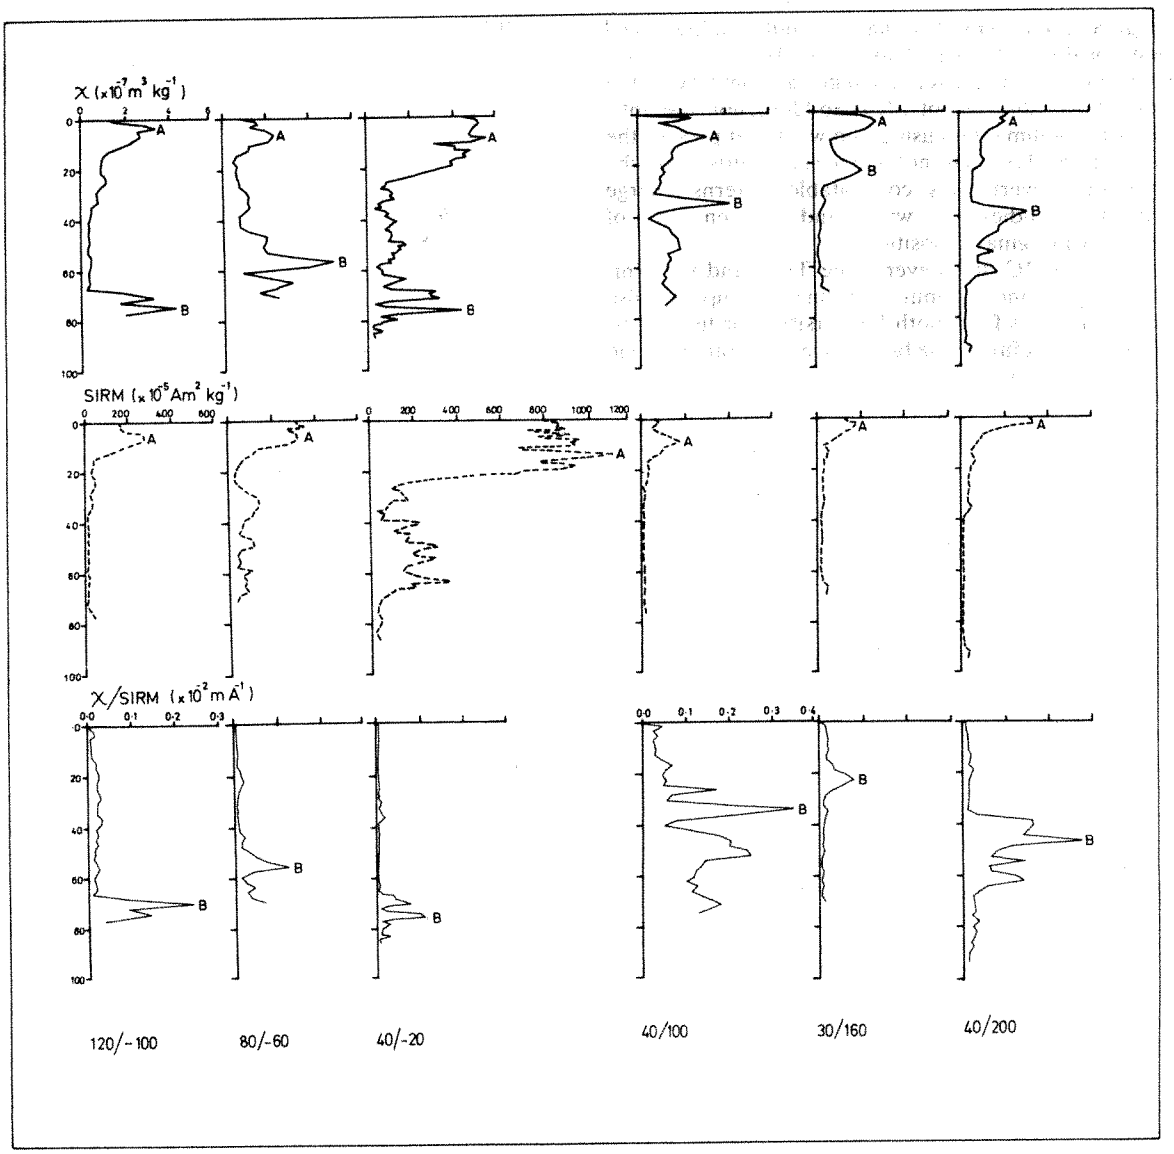

Fig. 2 Llyn Goddionduon. Single sample plots of χ, SIRM and χ/SIRM for six widely separated cores from the main grid. In all cases, the upper peak in χ and SIRM which gives low χ/SIRM values corresponds with the influx of magnetic minerals subsequent to a forest fire in 1951. The lower peak is clearly distinguishable from this in all cores by virtue of its high χ/SIRM ratios.

automatically immediately after sensing and it was thus possible to plan day-to-day field sampling priorities in the light of the results obtained within a few hours of taking each set of cores.

Subsequent studies based on extruded sediment have included measurements of specific susceptibility (χ), the intensity and direction of natural remanence (NRM), anhysteretic remanence (ARM), saturation isothermal remanence (SIRM) and coercivity of SIRM (B_{CR}). These magnetic measurements provide a wide range of rapidly calculated parameters and ratios which may be used to test core-correlation schemes. In addition chemical, particle size, loss-on ignition, pollen-analytical and radiometric studies are in progress.

Figure 1*b* shows whole core susceptibility traces for a selection of cores from the main grid of cores for the whole lake. In view of the paucity of Flandrian (Post-glacial) sediments in the tiny trench zone (<1 m in all 27 cores from only 5% of the lake), the complex deposition pattern of these cores has little effect on 'whole lake' investigations and the trench results can be satisfactorily assessed on the main 20-m grid. A 'tie-line' has been drawn down the length of the lake. The tie-line cores have been provisionally correlated using the scheme of whole core susceptibility peak matching indicated in Fig. 1*c* and substantiated in more detail by the plots of specific magnetic parameters from dried contiguous 1- or 2-cm subsamples presented in Fig. 2. The central zone in Fig. 1*b* reflects an area of more extended deposition within which the main susceptibility peak used in correlation lies below the depth of sediment penetrated by 1.3-m cores.

Figure 2 shows down core χ, SIRM and χ/SIRM ratios for dried sub-samples in, six widely separated cores located on Fig. 1. Peak χ/SIRM ratios associated with the main tie-line linking the sites, and low χ/SIRM ratios characteristic of the near surface peak (masked by the core tops in whole-core measurements) are common to all the cores and support the proposed correlation scheme. The uppermost sediment with low χ/SIRM ratio is attributable to the forest fire of 1951 (ref. 11) which occurred on the north-east edge of the drainage basin.

Studies in progress are designed to confirm the full pattern of correlation, to date each stage in accumulation, to characterise sedimentologically, chemically and magnetically the variations in deposition rate portrayed, and to relate them to the history of land use at the site decipherable in the pollen record. These studies will provide a basis for empirically based calculations of changing net sediment input versus age for almost all the lake basin for the time interval spanned by the majority of the cores.

Magnetic measurements now open up the prospect of core scanning and correlation with a speed, and on a scale, orders of

magnitude greater than conventional techniques allow. Well founded empirical calculations of total sediment input versus time thus becomes feasible even for lakes as complex as the present example. In the case of Llyn Goddionduon the anticipated pattern of sediment focusing into what is at present the deepest part of the lake has not been characteristic of the Flandrian period. Nevertheless, correlatable patterns emerge from the magnetic studies even within and between zones of relatively shallow marginal deposition.

We thank the NERC, the Leverhulme Trust and the Universities of Liverpool and Edinburgh for financial support, also colleagues and students from both Universities for field assistance, and we are grateful for the facilities in the Draper's Field Centre, Rhyd-y-Creuau.

^{210}Pb dating of annually laminated lake sediments from Finland

USE of ^{210}Pb dating is increasing rapidly and applications include studies of accelerated eutrophication in major lakes[1], salt-marsh accretion[2], the recent history of heavy metal pollution[3] and accelerating soil erosion resulting from subsistence agriculture[4]. As dating models have increased in variety and complexity, it is important to compare models against precise and unambiguous independently derived time scales. In each area of application of ^{210}Pb dating, the inferences drawn from the calculated age–depth curves and the estimates of changing flux rates are often highly dependent on the ^{210}Pb dating model used. In this report ^{210}Pb-derived estimates of lake sediment age and dry-mass sedimentation rates are compared with ages and rates calculated directly by counting annual laminations. The results support a model of ^{210}Pb dating which assumes a constant net rate of supply (c.p.s.) of unsupported ^{210}Pb to the sediment despite fluctuations in dry mass sedimentation rates. Our findings underline the need for empirical evaluation of alternative ^{210}Pb dating models in the widest possible range of contexts. They also cast doubt on some published studies in which strongly 'kinked' profiles of unsupported ^{210}Pb concentration have been interpreted within the framework of conventional constant initial concentration (c.i.c.) assumptions.

Most workers using ^{210}Pb dating have assumed the initial unsupported ^{210}Pb concentration to be constant throughout a dated profile, or at least in large sections of the profile. This assumption can be satisfied in theory by a direct association between sedimentation and unsupported ^{210}Pb supply[5], or by a combination of constant unsupported ^{210}Pb flux and constant dry-mass sedimentation for all of[6], or segments[7] of, each profile. Authors using c.i.c. models have dealt with sharply inflected or non-monotonic ^{210}Pb-versus-depth profiles, or individual 'anomalous' values, by invoking alternative explanations such as physical mixing[8], bioturbation[9], diffusion[10] and co-precipitation of ^{210}Pb with manganese[11]. Where authors have referred to the alternative basic assumption of a constant net rate of supply (c.r.s.) of unsupported ^{210}Pb to the sediment independent of fluctuations in bulk sedimentation rate this alternative has usually been dismissed in favour of some variant of the c.i.c. model[12,13], or else it has been used but not empirically tested in a rigorous manner[2,14,15]. Recent applications of c.r.s. model calculations[16] to lake sediment sequences in Northern Ireland, the Highlands of Papua New Guinea[17] and Lake Michigan[18] provide strong, varied, but essentially circumstantial evidence for the validity of c.r.s.-derived age–depth relationships and dry-mass sedimentation rates. In each of these case studies, as in the example by Robbins[15], the choice between alternative models has a major impact on the results and their interpretation.

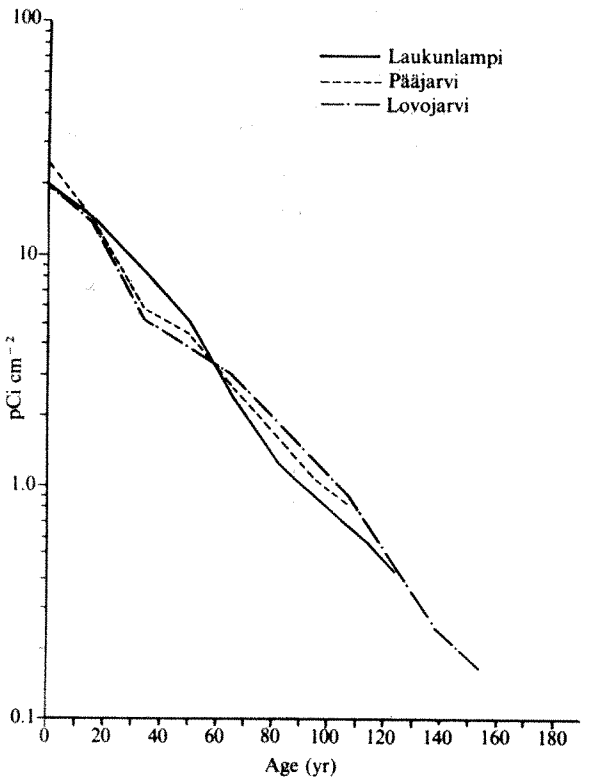

Fig. 1 Cumulative residual unsupported ^{210}Pb versus age in three annually laminated sediment profiles from lakes in east Finland. The approximation to a negative exponential function in each case confirms the validity of this as the appropriate dating parameter.

The sites from which the present evidence has been obtained provide a very precise and unambiguous basis for testing the alternative dating models. Not only are their recent sediments in the form of distinctive annual laminations, confirmed both biostratigraphically[19,20] and by ^{239,240}Pu and ^{137}Cs analyses (T. Jaakola, K. T., P. H. and S. Tiainen, unpublished), but they have also experienced disturbance in each catchment which has given rise to fluctuations in sedimentation rate strong enough to 'kink' the unsupported ^{210}Pb concentration-versus-depth curve.

In the c.r.s. model, the age t of sediments of depth x is calculated from[16]

$$A(x) = A(0)\,e^{-kt} \qquad (1)$$

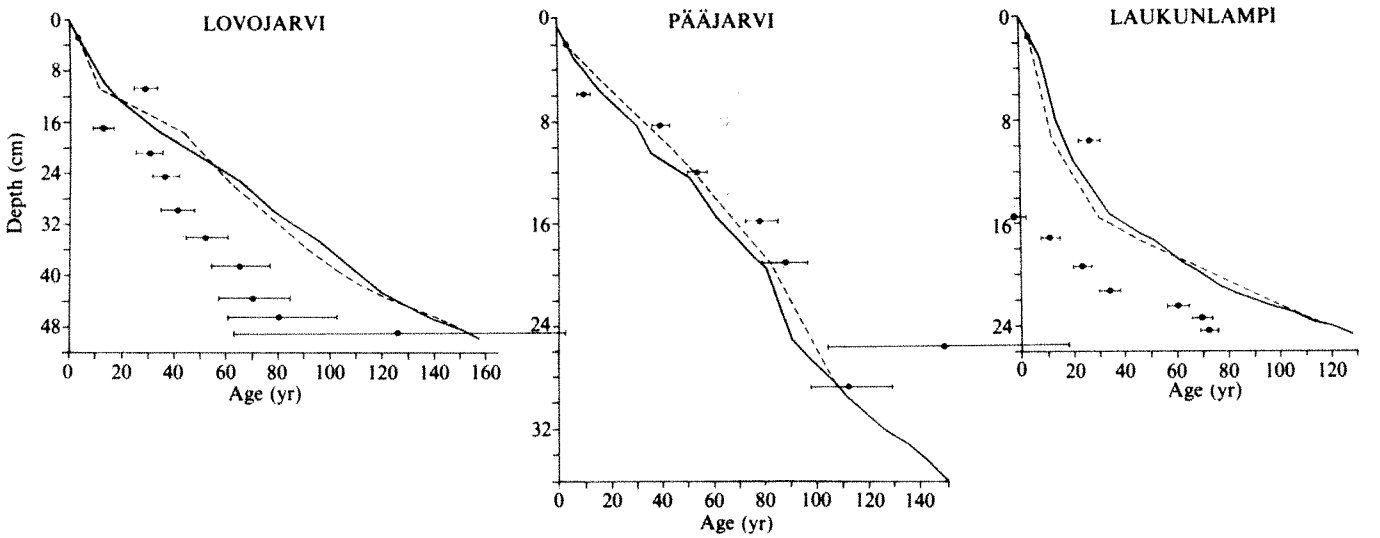

Fig. 2 Age–depth curves based on annual laminae- and on c.r.s.-model ^{210}Pb dating. ——, Laminae based curve; - - - -, c.r.s. model curve; ●, points on c.i.c. model.

where $A(x)$ is the residual unsupported ^{210}Pb beneath sediments of depth x, and k is the ^{210}Pb radioactive decay constant. The values of the dating parameter $A(x)$ for the Finnish lakes were calculated by numerical integration of the unsupported ^{210}Pb concentration with regard to the cumulative dry mass. The residual unsupported ^{210}Pb beneath the lowest datum point was estimated by assuming that the mean ^{210}Pb flux rate during the period covered by the observations was similar to the mean ^{210}Pb flux rate before this period. In Fig. 1, $A(x)$ is plotted against time for all three profiles, confirming the close approximation of this parameter to the theoretical relation expressed by equation (1). There is a close correspondence in the cumulative residual unsupported ^{210}Pb between sites, and hence in the ^{210}Pb flux rates, despite their physical separation, varied morphometry and contrasted sedimentation rates. The location and morphometric characteristics of each lake and drainage basin are summarised in Table 1, which also records mean ^{210}Pb flux rates, and total residual unsupported ^{210}Pb contents of each core.

Figure 2 compares for each site, the age–depth relationship derived from counting annual laminae, with the c.r.s. based ^{210}Pb age–depth profiles. In accordance with the assumption used in estimating the initial value of the dating parameter, the curves are synchronised at the lowest data point. The age–depth points derived using the c.i.c. model are also shown, although no attempt has been made to translate these into an age–depth

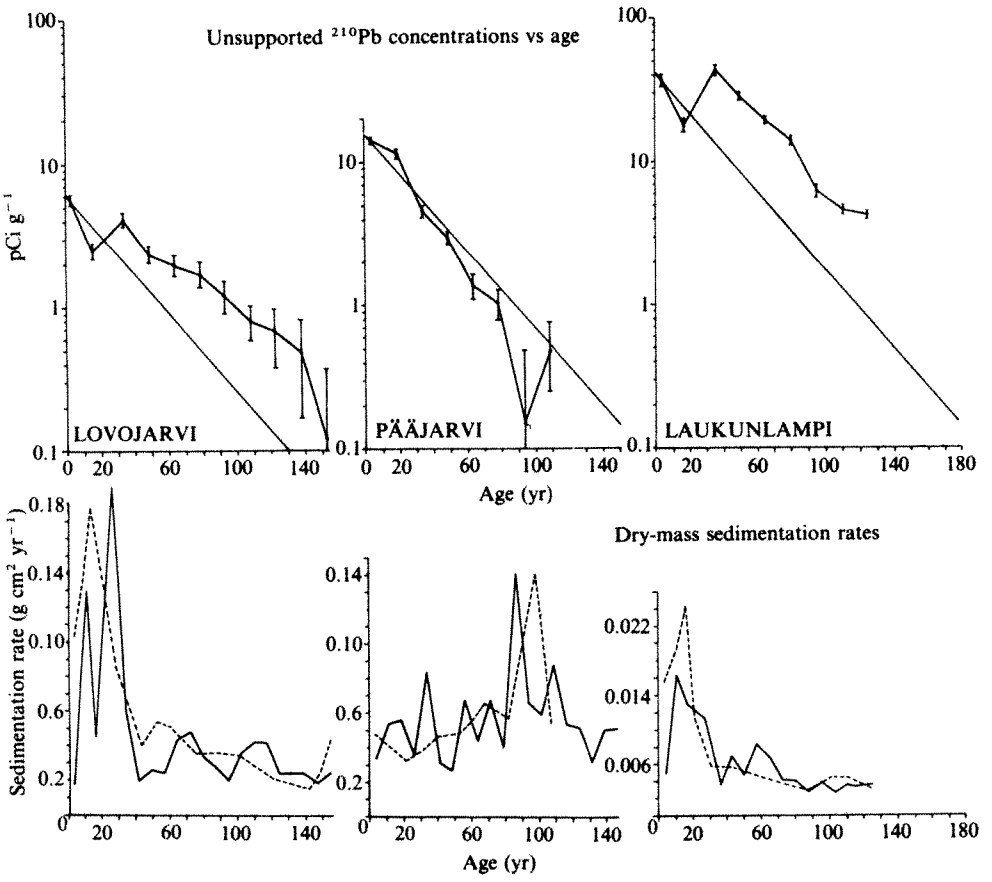

Fig. 3 Unsupported ^{210}Pb concentrations plotted against age (upper) and dry mass sedimentation rates based on annual laminae thickness and on c.r.s. model ^{210}Pb calculations (lower). In each sediment profile, the concentration-versus-age curve deviates significantly from the negative exponential function representing the expected radioative decay of ^{210}Pb and shown by the straight line. Each major inflection in the concentration-versus-age profile corresponds with peak dry-mass sedimentation rates determined from the annual laminae (——). Sedimentation rates based on c.r.s. model ^{210}Pb are shown as dashed line (- - -).

Table 1 Morphometric data, mean unsupported ^{210}Pb flux and total residual unsupported ^{210}Pb content

Lake	Area (A, hectare)	Drainage area (D)	D/A	Maximum depth (m)	Volume (m^3)	No. of direct inflows	Mean unsupported ^{210}Pb flux (pCi cm^{-2} yr^{-1})	Total residual unsupported ^{210}Pb content (pCi cm^{-2})
Lovojärvi 61°85′ N, 25°92′ E	4.8	570 hectare	119.1	17.5	36.9×10^4	6	0.65	20.09
Pääjärvi 61°04′ N, 25°05′ E	1,342.4	244 km^2	18.18	87	205.7×10^6	25	0.66	24.45
Laukunlampi 62°40′ N, 29°10′ E	8.4	21 hectare	2.5	26	—	0 (closed basin)	0.64	20.47

relation in view of their generally poor match with true age irrespective of which adaptation of the c.i.c. model is used.

Figure 3 shows changing unsupported ^{210}Pb concentrations plotted against time for each site compared with the dry-mass sedimentation rates derived from both the laminae counts and the c.r.s. calculations. In each case, depressed concentrations correspond with independently verified peak sedimentation rates, as required by the c.r.s. model.

At no point in any profile do the laminae- and c.r.s.-derived ages differ by more than 10 yr. At major points of inflection in each concentration-versus-depth profile, whether the inflections date from 5 to 10 yr or 100 yr before the year of sampling (1977–78), the c.r.s. calculations give an excellent approximation to true age. The close agreement is confirmed despite the need to interpolate between data points, an argument previously used to cast doubt on the validity of c.r.s.-based dating[13]. For dry-mass sedimentation rates, the agreement between laminae-based and c.r.s.-based estimates is less close partly because of the short time scale over which sedimentation rates appear to have varied in comparison with the ^{210}Pb sampling interval, and partly because the c.r.s. calculations of sedimentation rates are intrinsically more sensitive to the effect of experimental error than are the age–depth calculations. Nevertheless, the general characteristics of the changes in sedimentation rate are reasonably well portrayed by the c.r.s. calculations, within the limits of accuracy imposed by the sampling interval. Further studies incorporating mixing models[18], procedures for estimating patterns and rates of sediment focusing from ^{210}Pb measurements, comparison between ^{210}Pb derived ages and precisely dated influx events in non-laminated sediments, and systematic error analysis[21] are in progress. Treatment of over 40 ^{210}Pb profiles from 18 contrasted lacustrine and near-shore marine environments confirms that when independent tests of internal consistency and external validation can be applied to cases where dry mass sedimentation rates have varied through time, the c.r.s. model provides a better approximation to true age than do any of the alternatives. In no case encountered so far are any of the alternative dating models more accurate when used as a basis for estimating rates of sedimentation or mineral flux.

We thank J. D. Eakins (AERE, Harwell) for carrying out the analyses, and NERC, the Leverhulme Foundation and the Finnish Academy of Sciences for financial support.

Cinnamic acid inhibition of detritus feeding

AN important advance in ecology has been the general acceptance of Fraenkel's postulate that certain chemicals in plants deter herbivores[1–3]. Such chemicals are usually termed secondary plant substances because they are not involved in primary metabolic pathways. Very little of the annual production of biomass by higher plants is consumed by herbivores or phytopathogens[4]. Instead, most of the biomass becomes litter and eventually decays through the activity of decomposers. The secondary compounds that deter grazers while the plants are alive do not disappear immediately when plants senesce and die. We have therefore investigated whether these anti-herbivore substances continue to inhibit consumption by organisms feeding on litter or detritus. We report here that cinnamic acids, one type of secondary plant substances found in detritus, inhibit feeding by detritivores. This inhibition occurs at concentrations found in nature and may be a major factor controlling the rate of decay of organic matter.

In salt marshes most of the annual production by plants becomes litter. The most prominent saltmarsh plants in the eastern coast of the US are grasses of the genus *Spartina*. Unlike some grasses[5], tissues of *Spartina alterniflora* contain few or none of the compounds, such as condensed tannins, alkaloids or cyanogenic glucosides, which are the major deterrents to grazing in many terrestrial plants[2,6]. It seems likely that in *Spartina* the substances deterring herbivores are the soluble and insoluble esters of glucosides of hydroxyaromatic acids[7–9], also found in

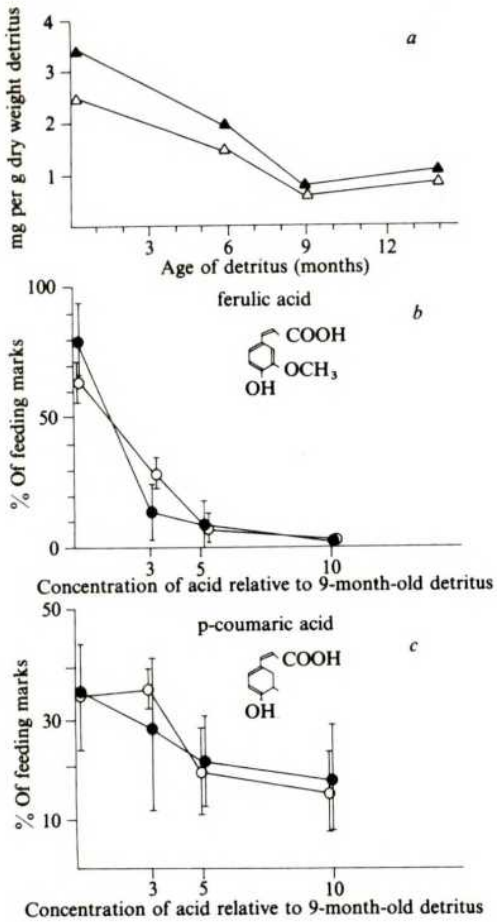

Fig. 1 *a*, Concentration of ferulic acid (▲) and coumaric acid (△) in litter of *Spartina alterniflora* of increasing age. *b*, *c*, Feeding response of *Orchestia grillus* (●) and *Melampus bidentatus* (○) to increased ferulic acid (*b*) and *p*-coumaric acid (*c*) in their food.

Sorgum bicolor[10,11]. These compounds are readily hydrolysed by hydrolases in the plant to form the actual deterrents, the corresponding free acids[10,11]. Our work focused on ferulic acid and *p*-coumaric acid (Fig. 1), cinnamic acids that are abundant in the cell walls of *S. alterniflora*.

We extracted free cinnamic acids from tissues of dead *S. alterniflora* in 80% methanol at 85 °C for 10 min. The extract was cooled for 20 min and filtered through a Millipore filter; the procedure was then repeated. The unhydrolysed extract of detritus of four different ages was analysed by TLC and spectrophotometry for ferulic acid (320 nm) (Fig. 1*a*). Both acids decreased in concentration with the age of the detritus so that after 9 months of natural ageing in the field only one-third of the initial concentration of cinnamic acids remained in the detritus.

We tested the effect of ferulic and *p*-coumaric acids on feeding by two saltmarsh detritus feeders, the amphipod *Orchestia grillus* and the snail *Melampus bidentatus*. We suspended ground, dead grass in agar in a Petri dish with four compartments. This agar suspension method of testing palatability was developed by Gieselman[12]. The amphipods and snails fed very well on the suspension and both species fed on the agar only when detritus was present.

We tested the effect of ferulic and *p*-coumaric acids by adding them to the agar suspensions of 9-month-old detritus of *S. alterniflora*, plating the suspensions, allowing the test animals to feed. The detritus was aged naturally in the field. We added 0, 3, 5 and 10 times the amounts of acids found in 9-month-old detritus, and each of these four doses was included in every Petri dish. To each of these dishes we introduced four amphipods or snails. The dishes were incubated in the dark for 3 h. Feeding was assessed by the number of feeding marks left on the surface of the agar suspension. Marks were easily counted and clearly reflected the difference in mouth parts and feeding mechanisms of the two species (Fig. 2).

An increase in the concentration of both ferulic and *p*-coumaric acids decreased feeding activity by both *O. grillus* and *M. bidentatus* (Fig. 1*b*, *c*). Ferulic acid was more effective than *p*-coumaric acid. When feeding on recently dead plant tissues, the detritus feeders are exposed to concentrations of these acids up to three times that found in 9-month-old detritus (Fig. 1*a*). We can expect, therefore, that detritus of 9 months or older could be significantly more palatable than new detritus due to the lower content of ferulic acid. Concentrations of more than five times the amount of *p*-coumaric acid in 9-month-old dead grass reduced feeding. Because we did not find such high concentrations in litter or detritus of *S. alterniflora*, *p*-coumaric acid may not be as important as ferulic acid in deterring detritus feeders.

The mechanism that makes ferulic acid distateful is unclear. Detritus feeders must taste the acidity as well as other flavours of the compound. In preliminary tests with ferulic acid buffered at neutral *p*H amphipods, but not snails, were inhibited, suggesting that some detritus feeders are deterred by acidity, whereas others are inhibited by sour or bitter tastes.

Other investigators have looked at microbial density and carbon and nitrogen contents as providing different ways of measuring the food quality of aquatic detritus[13,14]. Our evidence suggests that secondary plant substances such as ferulic acid are important in determining whether organic matter is consumed by detritus feeders. Further, because there are marked changes in the amounts of these compounds in litter as it ages and becomes detritus, the time at which food may become palatable

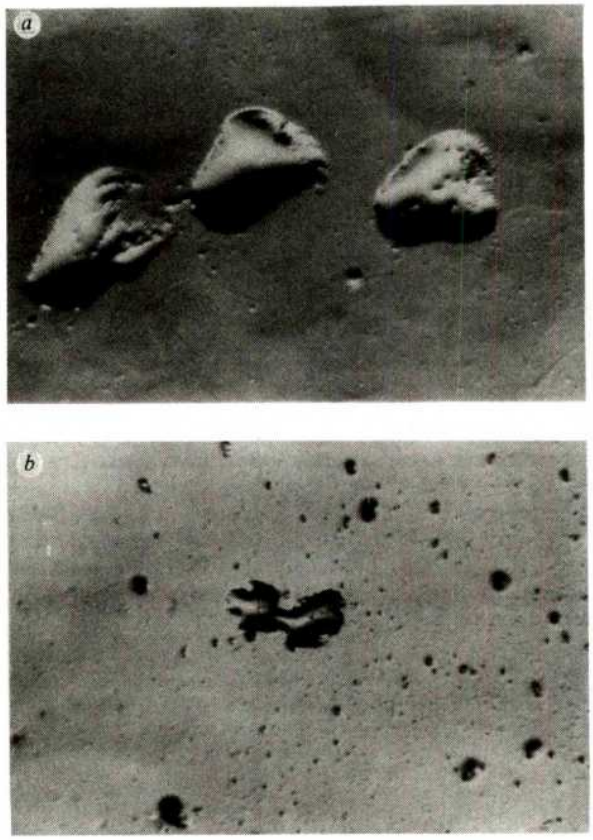

Fig. 2 Feeding marks of *Melampus bidentatus* (*a*) and *Orchestia grillus* (*b*) on the surface of an agar–detritus suspension. The marks are about 0.4 mm for *M. bidentatus* and 0.3 mm for *O. grillus* at their longest dimension. The radular marks left by the snail (*M. bidentatus*) are single whereas the amphipod (*O. grillus*) leaves double marks as a result of biting with paired mandibles.

to decomposers may also be determined by secondary plant substances.

The rate of decay of organic matter is accelerated by the comminuting of detritus by detritivores. The smaller particles provide new surfaces for microbial attack. Further, passage of detritus through the digestive system of detritivores also alters the nature of the particles, facilitating microbial reinvasion and also accelerating rates of decay. Secondary plant substances present in detritus, by inhibiting feeding by detritivores, thus delay the rate at which organic matter decays. It is also possible that microbial activity itself may be inhibited by such substances. This needs study, but it is clear that cinnamic acids, inherited from live plants, and perhaps other compounds, have a critical role in determining rates of decomposition of detritus. Thus, secondary plant substances may be a major control mechanism in ecosystems such as marshes where the detritus food web dominates the flow of carbon.

Isolation and cultivation of diatom symbionts from larger Foraminifera (Protozoa)

THERE has been increasing interest in larger Foraminifera that have symbiotic algae which apparently adapt them to thrive in certain shallow, nutrient-poor tropical seas where they are responsible for a significant or even dominant fraction of the carbon fixed in the benthos[1,2]. Studies of fine structure of several species of these giant protozoa have suggested that their algal symbionts are diatoms[6–12] without frustules (shells). This suggestion is itself remarkable because almost all marine invertebrate–brown algal associations (for example, those of corals and tridacnid clams) involve dinoflagellates. Unfortunately, knowledge of the architecture of the frustule is needed for the identification of a diatom. However, because the formation of the outer envelopes of the dinoflagellate and chlorophyte endosymbionts of other large species of Foraminifera is repressed within the hosts[6,713] but not in culture[5,14], we hoped that if the diatom endosymbionts could be isolated and cultivated they would form characteristic frustules. We report here the successful isolation and cultivation of diatom symbionts from foraminifera.

With the aid of SCUBA, *Heterostegina depressa*, *Amphistegina lessonii*, *A. lobifera* and *A. papillosa* were collected at 20–35 m in the Gulf of Elat (Red Sea) near Geziret Faraoûn anchorage. Individual animals were placed immediately in sterile dishes and under a dissecting microscope they were meticulously and aseptically brushed, scraped and washed through successive baths of antibiotic-containing sterile seawater to remove all external algae[5,14]. After processing, each animal was examined with a water immersion lens of a compound microscope to assure removal of all external algae. Individual animals were transferred aseptically to test tubes of sterile seawater and crushed carefully with sterile glass rods to release the symbionts. The algae were then inoculated into isolation media[15].

Growth of algal colonies was observable under a dissecting microscope after 4–8 d. The growth of large numbers of colonies of the same types[15] from each host is strong evidence that the algae isolated were not contaminants. If the isolates were undigested food organisms, then their hosts were filled with them. Growth of transfers was poor and restricted to media containing vitamins B_{12}, thiamine, biotin or mixtures of vitamins (media 15, 17 and 18)[15]. The isolates are now being maintained in a natural seawater medium (~40‰) enriched with: 10 mg % (w/v) yeast extract, 1 ml % (v/v) soil extract, 0.1 μM vitamin B_{12}, 1 μM biotin,and 1 μM thiamine.

All isolates were small pennate diatoms (3–14 μm), and two were previously undescribed. Some Foraminifera contained two

or rarely three different diatom species. A very small new species of *Fragilaria* (Fig. 1) was found in specimens of all three species of *Amphistegina*. *Nitzschia panduriformis* v. *continua* was found in *Heterostegina depressa* and a few *A. lobifera* (Fig. 2). Several *A. papillosa* contained an unusual new naviculoid diatom (Fig. 3). *Amphora tenerrima*, perhaps an episymbiont, was isolated from the exterior surfaces of both *H. depressa* and *Amphisorus hemprichii*. A manuscript containing full descriptions of the new diatoms is in preparation. None of the symbiont-diatom species was abundant in the epiphytic community at the time of collection.

Traces of chlorophyll *b* in extracts of pigments from intact animals suggested that *Amphistegina* spp. and *Amphisorus hemprichii* also contained symbiotic zoochlorellae. We isolated and grew clones of green algae from them.

The isolation of these symbionts paves the way for physiological–ecological studies which will advance our understanding of the carbon budgets and depth distributions of their hosts. When it is possible to obtain aposymbiotic hosts without killing them, we should be able to satisfy Koch's postulates and explore questions of host specificity and host–symbiont interactions. Research along these lines will be particularly exciting because algal endosymbiosis may have been a driving force in the evolution of these giant protozoa and a key to their great success.

Changes in the circuitry of the kitten visual cortex are gated by postsynaptic activity

MOST neurones in the visual cortex of normal adult cats are binocular and respond very selectively to elongated contours of a particular orientation[1]. If a kitten is deprived of vision in one eye during a critical period in early life the afferents from this eye lose the ability to excite cortical cells[2]. This functional deafferentation is, however, reversible if, still within the critical

0028–0836/79/270058—03$01.00

© Macmillan Journals Ltd 1979

period, the previously open eye is closed and the other opened[3]. These changes in afferent connectivity are attributed to competitive interactions between the pathways from the two eyes[4,5], which have been shown to occur at the level of the striate cortex[6]. We previously demonstrated[7] that afferents from the deprived eye remain functional when activity from the open eye is enhanced but fails to drive the common cortical target cell. This had suggested that the competitive suppression of one subset of converging afferents requires, in addition to imbalance in presynaptic activity, that the postsynaptic neurones actually respond to the more active pathways. Such postsynaptic gating was first postulated by Hebb[8], and since then it has been assumed in most models on adaptive neuronal connections. In the study reported here more direct evidence for the participation of postsynaptic factors both in competitive suppression and in functional recovery of converging afferents was obtained. The results support Hebb's early hypotheses and demonstrate that both changes in connectivity are in fact guided by postsynaptic response properties.

Three kittens were dark reared until the age of 5 weeks and then, with one eye closed, exposed to a normal environment for 9 consecutive days. Control experiments and a number of previous studies have shown that by this time most cortical cells have become dominated by the open eye and display orientation selectivity comparable to adult standards. At this age the initial shift in ocular dominance can still be reversed when the previously open eye is closed and the deprived eye opened[3]. If this functional reorganisation of afferent connectivity required responses from postsynaptic cells the following prediction can be made: when the spectrum of orientations visible by the open eye is restricted to a narrow range, reversal in ocular dominance should occur only for those neurones whose response properties enable them to react to the range of visible orientations. Cells with other orientation preferences that have no predisposition to respond to the signals from the open eye should remain connected to the eye that was open first and had experienced the normal environment.

We used artificial astigmatism[9] to produce effective restriction of the range of visible orientations during this second exposure period. A cylindrical lens of −25 dioptres was mounted in a polyurethane mask and fitted in front of the initially deprived eye while the other, previously open, eye was occluded. Photographs taken through the lens of the environment in which the kittens were exposed confirmed that only orientations within ±10° of the zero axis of the lens remained visible. Apart from the minimal counter-rotation of the eyes (~10% of tilt angle[10]) this range remains constant with respect to retinal coordinates regardless of head and body movements. The kittens were therefore allowed to freely explore their environment, which contained high-contrast contours of all orientations. In two kittens vision was restricted to horizontal orientations and in one to vertical orientations. After 10 days of 10 h exposure daily (during the night the kittens were returned to the dark room) the kittens were again kept in the dark for a few days until the experiment. For convenience the eye that was open first is referred to here as the 'first eye', and the eye that had seen only the restricted range of orientations is referred to as the 'second eye'.

The preparation and recording techniques were conventional and are described elsewhere[11]. The orientation selectivity and the ocular dominance of single neurones in area 17 were determined from manual field plots and from additional averaged response histograms.

As expected, after sequential monocular occlusion, the large majority of neurones were monocular (Fig. 1*a*); but the reversal of ocular dominance was incomplete. The second eye had regained dominance only over those cells whose receptive field orientations matched the visible spectrum of orientations (Fig. 1*b*). In these cells the afferents from the first eye had become ineffective; they remained, however, efficient in neurones whose orientation preference did not correspond to the range of orientations seen by the second eye (Fig. 1*c*). This indicates that circuit changes had occurred only for those neurones whose functional predisposition had enabled them to react to the activity from the second eye.

This conclusion is further supported by the distribution of orientation preferences of cells in different ocular dominance classes. Comparison of Fig. 1*e* and *f* shows that these polar distributions are complementary to each other. As expected, the cells which are now dominated by the second eye (ocular

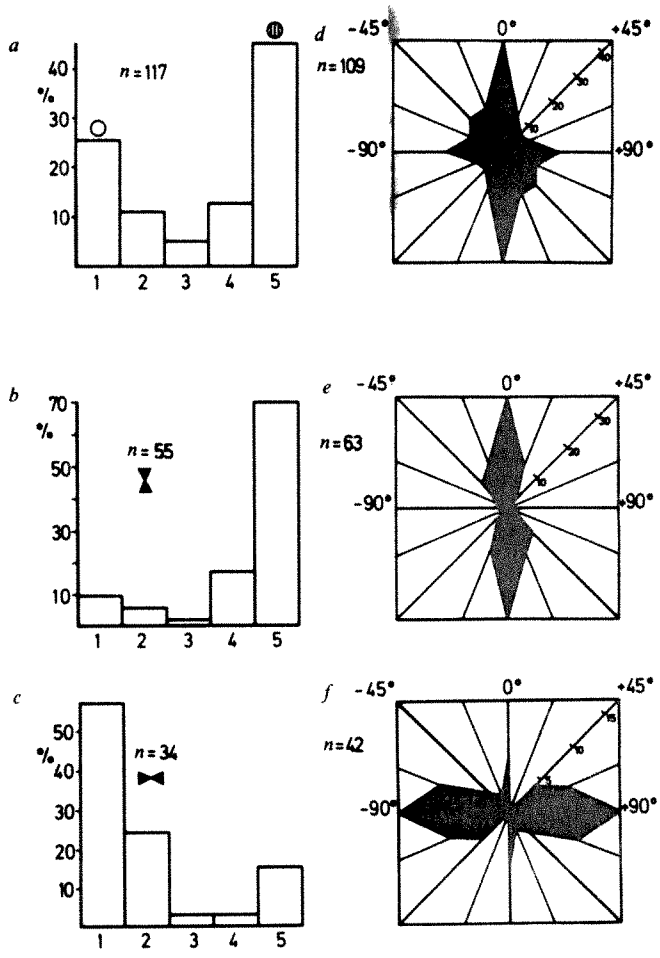

Fig. 1 Ocular dominance (OD) distributions (*a–c*) and orientation preferences (*d–f*) of neurones in the visual cortex of three kittens after reversal of monocular deprivation and selective exposure of the newly open eye to a narrow range of orientations. Number of neurones analysed, 176; those responsive to light, 127 (72%); those visually unresponsive, 49 (28%). Both ocular dominance and orientation selectivity fully determined, 117. Orientation selective or orientation biased, 109 (93%); non-orientated, 8 (7%). Ocular dominance distributions are plotted separately: *a*, for all neurones together irrespective of their orientation preference; *b*, for neurones with orientation preferences corresponding to the orientation (±22.5°) experienced by the second eye; and *c*, for neurones with orientation preferences orthogonal (±22.5°) to those experienced during the second stage of exposure. OD classes 1 and 5 refer to monocular cells excitable exclusively from the originally open eye (class 1) and the eye that was open last and viewed a narrow range of orientations (class 5). OD class 3 comprises binocular cells that are equally responsive to either eye and classes 2 and 4 contain binocular cells in which the first or second eye, respectively, is dominant. Polar plots of preferred orientations: *d*, independent of ocular dominance; *e*, for neurones driven monocularly or predominantly by the second eye; *f*, for neurones driven monocularly or predominantly by the first eye. The radius of the graph at each intersection gives the number of cells with that particular orientation preference. Angles from 0 to ±90° correspond to the difference between the orientation that was seen by the second eye and the neurones' preferred orientations.

dominance classes 4 and 5, Fig. 1*e*) have orientation preferences that match the narrow range of orientations visible during the second stage of exposure. In addition, cells with these properties are under-represented in the population of cells still dominated by the first eye (ocular dominance classes 1 and 2, Fig. 1*f*). This complementarity in orientation preference indicates that: (1) cells now dominated by the second eye were recruited from the pool of neurones initially dominated by the other eye; and (2) this recruitment must have been guided by the response properties of the cortical cells recruited.

These results all support the hypothesis that both suppression and enhancement of excitatory transmission in converging pathways are gated by a matching process between the pattern of presynaptic activity and the response properties of the common postsynaptic target cell. Thus, for the present paradigm, Hebb's[8] classical postulates on adaptive synaptic connections appear to be fully confirmed. Transmission is enhanced selectively in those pathways that are capable of exciting the postsynaptic target and are contingently active with the latter. On the other hand, those afferents which fail to excite the postsynaptic target become suppressed while the target is activated by other converging afferents. Such a mechanism implies then, that activity from the eyes can only select from among preexisting connections and only within the limits set by the response properties of the postsynaptic targets. Moreover, as functional recovery after reversal was guided by postsynaptic responses, as apparent from the complementary orientation distributions, one has to infer that the initial disconnection has not been completed by the time of reversal. In view of the short period of preceding monocular deprivation and the rapid recovery after reversal it seems possible that, at this early stage of monocular deprivation, synaptic transmission through the deprived pathway is only weakened while the connections themselves persist. This would allow at least sub-threshold activation or even occasional spiking of the cortical target cells in response to stimulation of the deprived eye. Such activation would then act as the postsynaptic signal for initiating the re-establishment of fully functioning synaptic connections.

While this manuscript was in preparation Cynader and Mitchell[6] reported experiments in which previously inexperienced kittens were exposed with one eye to a restricted range of orientations while the other was allowed to view normally. They found orientation-dependent changes in ocular dominance and therefore concluded that the competitive interactions between afferents from the two eyes occur at the cortical level. Our present data fully support this conclusion and advance the results of Cynader and Mitchell in that they provide the neuronal mechanism through which the response properties of postsynaptic target cells gate the consolidation and the disruption of converging afferents. The generality of the mechanism proposed in this report is emphasised by the fact that it not only predicts correctly the disruption of pathways observed by Cynader and Mitchell but also, as described above, the selective recovery of previously inactivated connections.

Orientation of horizontal cell axon terminals in the streak of the turtle retina

NEURONES which respond preferentially to slits of light of a given orientation have been found at the ganglion cell level of the retina[1], as well as at higher centres of the visual system[2–4]. Present knowledge about the morphology of such cells and the organisation of the inputs to these cells does not account for the origins of their specialised receptive field properties. We report here that the horizontal cells impaled in the visual streak of the turtle retina (a specialised linear area centralis[5] analogous to the fovea of higher vertebrates) respond preferentially to slits of light oriented parallel to the streak and thus parallel to the horizontal meridian of the animal's visual field[5]. Anatomical studies demonstrate that these horizontal cells are all elongated and oriented in the direction of the streak. Thus, our findings show that a class of neurones exists in the retina whose morphologies may form the basis for their specialised receptive field properties.

The techniques used for intracellular recording from neurones in the eyecup of the turtle, *Pseudemys scripta elegans*, and the criteria for horizontal cell identification, have been described previously[6–8]. The light stimulus was a slit, 0.1 mm wide and 3.0 mm long. The centre of the impaled unit's receptive field was determined as the position yielding the largest response to flashed slits of light oriented along two mutually perpendicular axes.

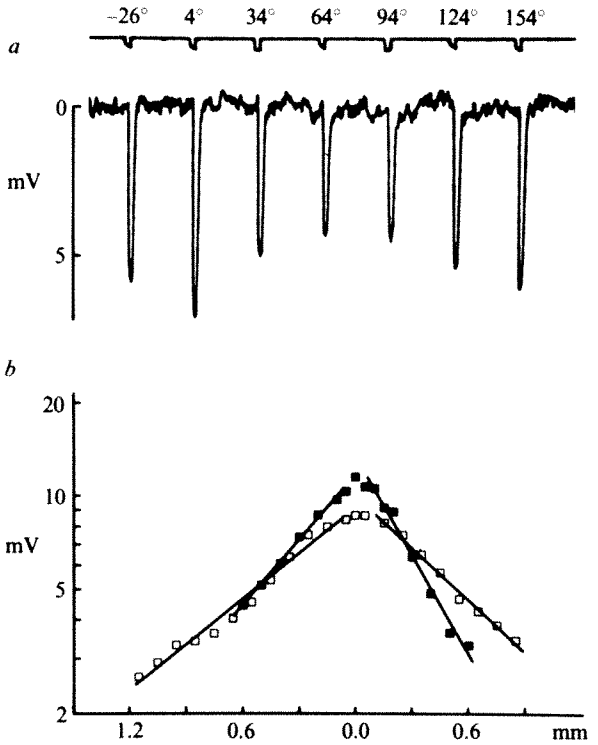

Fig. 1 Receptive field asymmetries in an L_1-type horizontal cell in the visual streak of turtle retina. *a*, Photoresponses to slits of dim light centred over the receptive field and flashed at 6 s intervals with the orientations given on top of the figure. Angles were measured with respect to the streak orientation (defined as 0°). *b*, Semilogarithmic plot of the peak amplitudes of photoresponses to slits of light as a function of displacement of the slit along directions parallel (□) and orthogonal (■) to the streak. Lines drawn through data points are the best fit to an exponential as determined by a least squares criterion. The slit intensity in B was 3 times that used in A. The maximum response elicited in this unit with bright, 3.2 mm diameter spot illumination was 40 mV.

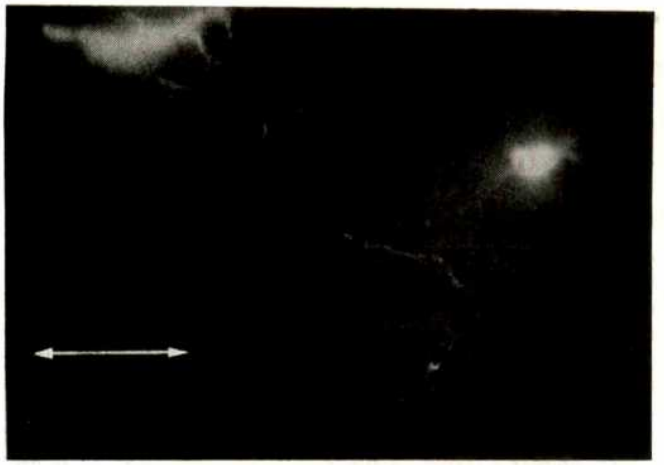

Fig. 2 Lucifer-stained horizontal cell from which intracellular responses of Fig. 1 were recorded. Lucifer has stained the axon terminal (upper left), axon and cell body. The recording site was the axon terminal as indicated by Fast Turquoise marking. Streak direction and scale are indicated by arrow. Scale bar, 30 μm.

The receptive field properties of seventeen luminosity type horizontal cells (L_1-type) lying within 75 μm of the visual streak of the turtle retina were studied. A slit of dim light intensity was centred over the unit's receptive field and flashed at various orientations. Typical responses are shown in Fig. 1*a*. In this unit, as in all others, the smallest and largest responses were elicited by slits of light oriented approximately perpendicular and parallel to the streak, respectively. The ratio of the smallest to the largest amplitudes recorded (the response eccentricity) was 0.59 for the unit of Fig. 1*a* and the average for all seventeen units was 0.66 ± 0.1 (s.d.).

This non-isotropy in the receptive fields was further investigated in eight units by measuring space constants[9] in directions parallel and orthogonal to the streak. Figure 1*b* shows a semi-logarithmic plot of peak voltage against slit displacement. The response evoked when the slit was centred over the unit (0.0 in Fig. 1*b*) and parallel to the streak (filled squares) was larger than that evoked by a slit orthogonal to the streak (open squares). Furthermore, the decay of potential with distance from the centre of the receptive field was approximately exponential along each axis and the fall off was greater for slit displacements in the direction perpendicular to the streak (filled squares). The space constants measured on each side of the unit's receptive field centre were different and were averaged to give a mean space constant for each direction. For the unit of Fig. 1*b*, the mean space constants for displacements orthogonal and parallel to the streak were 535 μm and 831 μm, respectively. The ratio between the two space constants provides an index of the asymmetry of the receptive field, and was 0.64 for this unit and 0.73 ± 0.09 on the average.

Lamb[9] has shown that for dim intensities, the response V, evoked by a slit of width a, centred over a horizontal cell receptive field is related to the space constant λ, by the function $V = E(1 - \exp(-a/2\lambda))$ where E is the response of the cell to a full field stimulus. In this model, λ is related to the sheet and membrane resistances, R_s and R_m, respectively, by $\lambda = (R_m/R_s)^{1/2}$. We have modelled the horizontal cell network in the streak as a two dimensional conductive sheet where the sheet resistance differs in directions parallel and perpendicular to the streak. For this non-isotropic model, the ratio of the voltages calculated for λ values parallel and perpendicular to the streak, $V_\perp/V_\parallel$, gives an expected response eccentricity which can then be compared to the measured response eccentricity. For the conditions of the experiments described here, $a/2\lambda \ll 1$, so this ratio can be approximated by $V_\perp/V_\parallel \simeq \lambda_\parallel/\lambda_\perp$. Because the measurements of response eccentricities and space constants were both functions of intensity, data obtained with the same intensity slit were used for a meaningful comparison. The mean difference between predicted and measured response eccentricities was 0.01 ± 0.08. These findings support the view that the receptive field asymmetries of L_1 horizontal cells as revealed by measurements of space constants and response eccentricities reflect summation within a linear, but anisotropic network where the attenuation of signals is greater in the direction perpendicular to the streak than parallel to it.

Intracellular injection of a mixture of Fast Turquoise[10] (1.2%) and the fluorescent dye, Lucifer[11] (3%), was attempted in all seventeen L_1 units and an example is shown in Fig. 2. All six successful stains revealed axon terminals which were elongated and oriented parallel to the streak. In some instances, a faintly stained axon and cell body were also visible (Fig. 2). Luminosity type horizontal cells in the turtle, as in other species, have an axon terminal and a cell body which are connected by a fine axon[11–13] but which are electrically independent[7,12]. The brighter stains of axon terminals, and the Fast Turquoise marking indicate that the L_1 units are axon terminals.

Anatomical studies of Golgi-Colonnier impregnated horizontal cells in the streak region of the turtle retina provided a morphological correlate for the physiological findings described above. All Golgi-impregnated axon terminals of horizontal cells in the streak region were observed to be elongated and oriented parallel to the streak as shown in Fig. 3. Each axon terminal consisted of a thick, tuberous process 8 μm in diameter and 50 μm in length with numerous small terminals projecting to the photoreceptors. Each axonal arborisation occupied an approximately rectangular space on the retina, with mean dimensions of 20×50 μm. Also shown in Fig. 3 is a cell body of a horizontal cell with its fine axon.

The actual dimensions of the axonal arborisations (Fig. 3) cannot account for the large receptive fields measured in L_1 units of the turtle streak. There is considerable physiological[7,9,14–18] and anatomical[19–23] evidence that horizontal cells in the vertebrate retina are extensively electrotonically coupled via gap junctions, thereby forming a conductive sheet across the retina. The elongated shape of the axon terminals in the turtle streak, and their common orientation parallel to the streak suggests that

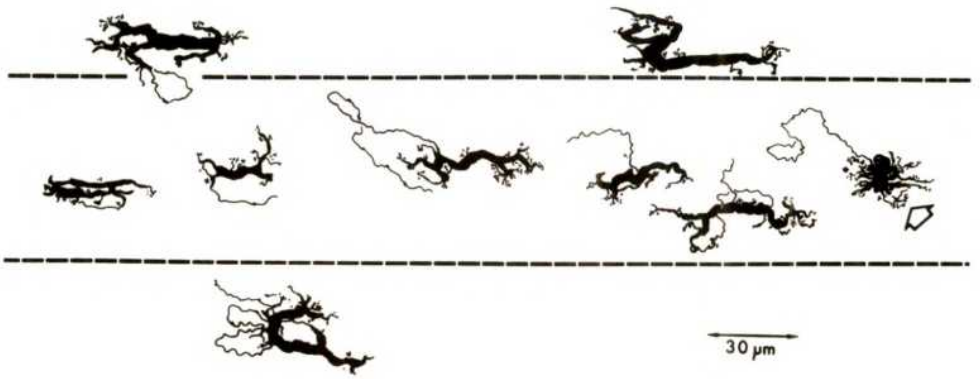

Fig. 3 Drawings of Golgi-Colonnier impregnated horizontal cell axon terminals in the visual streak region (area between dashed lines). The axon terminals are connected via the thin curly axon to horizontal cell bodies of the type illustrated (arrow). The axon terminals have arborisations elongated in the direction of the streak.

the mean distance between gap junctions linking neighbouring L_1 units should be greater in the direction parallel to the streak than perpendicular to it. Assuming that cytoplasmic resistance is much lower than junctional resistance, the signal attenuation will occur mainly at these junctions. We further assume a uniform distribution of gap junctions along the cell surface. The signal attenuation per unit length normal to the slit stimulus will then be greater in the direction perpendicular to the streak resulting in receptive fields elongated along the streak.

The mechanism described above is based upon a network of L_1 units each of which has a common orientation. A random distribution of orientations of elongated cells would result in more equal mean distances between junctions along any two orthogonal directions. This type of anatomical arrangement is in fact seen in Golgi-impregnated L_1-type horizontal cells in the peripheral retina. Here, our preliminary physiological findings indicate that L_1-type horizontal cells have response eccentricities closer to 1.0 with no consistently observed preferred orientation along any particular axis.

In this paper, we have shown that the streak region of the turtle retina contains at least one population of cells with specialised properties; the axonal arborisations and the receptive fields of L_1 horizontal cells in this region are elongated in the direction of the streak. The functional significance of the specialisations in the streak region may be better understood from ganglion cell recordings in this region. However, such measurements have only been made in the visual streak of another species, the rabbit[1]. Amongst rabbit ganglion cells in this region, orientation selective units were found which responded only to slits of light which were oriented either parallel or perpendicular to the streak. Although a full understanding of receptive fields at the ganglion cell level requires a greater knowledge of signal processing in the inner and outer plexiform layers, the oriented horizontal cell receptive fields described here may have significance for the development of orientation specificity in the visual streaks of species whose retinas contain this specialisation.

We thank Walter Stewart for Lucifer dye, and E. I. DuPont deNemours & Co. (Inc.) for the Pontamine Fast Turquoise. We thank Drs K. I. Naka and J. Schnapf for reading the manuscript and Dr R. Nelson for useful discussions.

Involvement of cyclic GMP phosphodiesterase activator in an hereditary retinal degeneration

CYCLIC NUCLEOTIDES mediate many aspects of normal cellular metabolism[1]; thus, degradation as well as synthesis of these intracellular mediators must be strictly regulated. Phosphodiesterase (PE), the enzyme of cyclic nucleotide catabolism, is present in mammalian tissues in multiple forms, which differ in substrate specificity, kinetic characteristics and subcellular localisation[2]. Moreover, a calcium-dependent protein activator (now called calmodulin) has been characterised that specifically activates at least one of the PDE types[3,4] although other types of PDE are known to be activator independent[5,6]. Thus, several mechanisms are present *in vivo* which allow strict control of PDE. A unique cyclic GMP-PDE is compartmentalised in the outer segments of retinal photoreceptor cells[7–10]; its activity is low in the dark-adapted state but increases dramatically on light adaptation[10–12]. The resulting drop in cyclic GMP content could serve as a chemical 'signal' in the normal visual process[13,14]. However, despite much investigation of various cyclic nucleotide systems, no definitive information has been obtained which clearly links a disorder of cyclic nucleotide metabolism with a disease process elsewhere than in retina[15,16]. We have recently presented preliminary evidence that an abnormality in cyclic GMP metabolism could be present in the

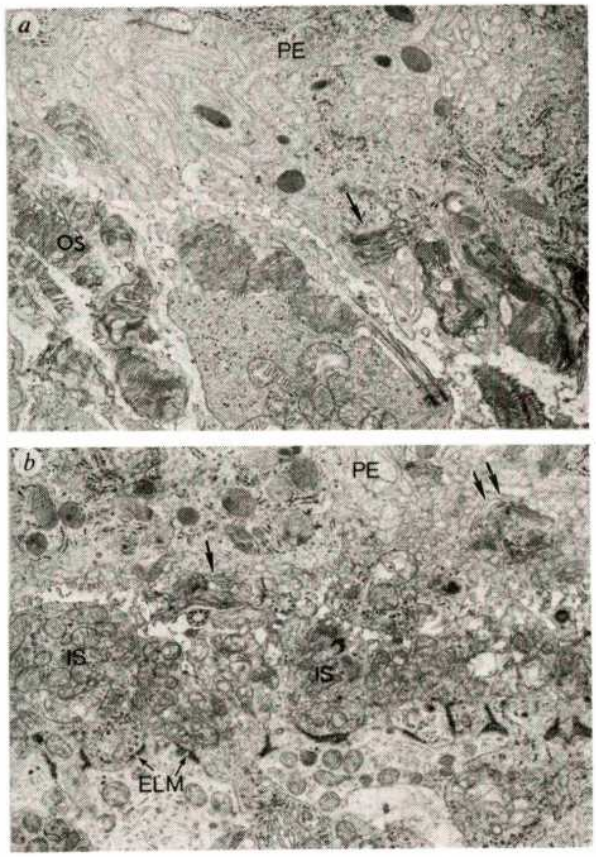

Fig. 1 *a*, Photoreceptor layer from a 13-d-old normal Irish setter. Photoreceptor outer segments have begun to elongate and contain well organised stacks of outer segment (OS) lamellar disks. Some of these seem to have been engulfed (arrow) by the pigment epithelium (PE). *b*, Photoreceptor layer from a 13-d old affected Irish setter. Small photoreceptor inner segments (IS) project through the external limiting membrane (ELM). There is minimal outer segment material; some is apposed to the PE apex (arrow) and some seems to be located within the PE cytoplasm (double arrow) ×10,400.

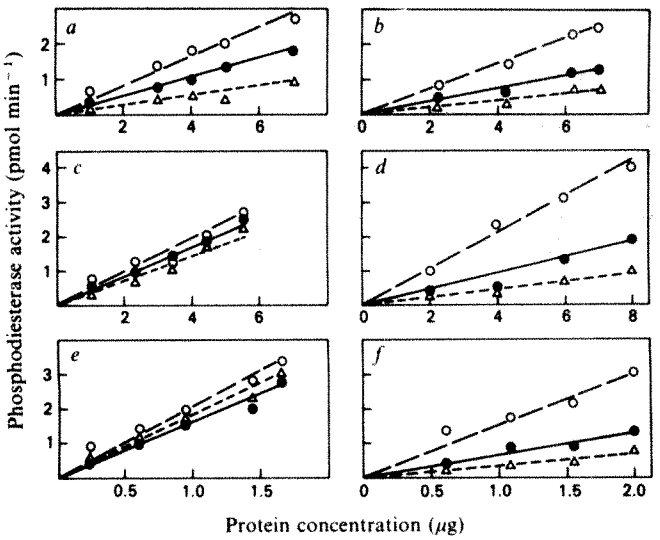

Fig. 2 Cyclic GMP phosphodiesterase activity in retinas of different ages. *a*, Control 9-d-old; *b*, affected 9-d-old; *c*, control 31-d-old; *d*, affected 34-d-old; *e*, control 48-d-old; *f*, affected 48-d-old. ●, No additions; ○, 10 μg purified brain activator added; △, 250 μM EGTA added. Experimental points are averages of triplicates which differed by no more than 15%.

retinas of Irish setter dogs with inherited rod–cone dysplasia[15] that could lead to greatly increased cyclic GMP content, as had been reported in mice with inherited retinal degeneration[16]. We now report that the basic defect in the disease seems to be a failure to switch PDE type and a concomitant decrease in protein activator concentration early in postnatal development, at the time of photoreceptor differentiation.

The Irish setters used were bred to develop rod–cone dysplasia, and controls were heterozygous Irish setters unaffected by the disease. Tissues were obtained as previously described[15]; briefly, animals were anaesthetised with pentobarbital, their eyes enucleated and the retinas quickly dissected on ice and frozen in liquid nitrogen. Protein was determined by the method of Lowry *et al.*[17] with bovine serum albumin as standard. Bovine brain activator and activator-deficient PDE were prepared as previously described[18]. The activator-deficient enzyme had a basal activity of 930 pmol cyclic AMP hydrolysed per mg protein per min; this was increased fourfold in the presence of optimal concentrations of Ca^{2+} and activator protein. PDE activity was measured using an assay mixture containing 40 mM Tris-HCl (*p*H 8.0), 3 mM $MgSO_4$, 50 μM $CaCl_2$, 1 μM ^{3}H-cyclic AMP (36.6 Ci mmol^{-1}) or ^{3}H-cyclic GMP (8.28 Ci mmol^{-1}) (NEN) and an appropriate amount of retinal homogenate in a total volume of 100 μl. When appropriate, 250 μM EGTA or 10 μg of purified brain activator was added before PDE assay. Samples were incubated for 12 or 15 min at 30°C, the reaction was terminated by boiling for 45 s, and 50 μg snake venom (*Crotalus atrox*, Sigma) was added. Samples were incubated for a second 10-min period at 30°C and 1.0 ml of IRP-58 resin (200–400 mesh, Rohm and Haas) added. After centrifugation, ^{3}H-adenosine or ^{3}H-guanosine in the supernatant was determined by liquid scintillation spectrometry. Recovery of ^{3}H-nucleoside was >90%. Retinal protein activator was assayed by testing its ability to stimulate the activity of activator-deficient, purified cyclic nucleotide PDE enzyme (0.68 μg per 0.1 ml assay mixture) using boiled retinal aliquots as the source of activator. One unit of activator is defined as the amount required to give half-maximal stimulation of the activator-deficient PDE enzyme.

The second week after birth is critical in retinal development in dogs, as the photoreceptors begin to differentiate during this period (Fig. 1). At day 9 (Table 1 and Fig. 2*a*, *b*), cyclic GMP-PDE activity was already lower in the dystrophic dog (244 pmol per mg protein per min) than in heterozygous controls (309 pmol per mg per min). However, cyclic AMP-PDE activity was the same in affected and control retinas at 9 days. Cyclic GMP-PDE activity in control retinas rose sevenfold (Table 1) by the time of photoreceptor maturation at 7 weeks[19]. Cyclic GMP-PDE activity observed in affected retinas during development was lower than that of control retinas, whereas no difference was observed in cyclic AMP-PDE activity (Table 1). Measurement of endogenous protein activator for cyclic GMP-PDE using activator-deficient brain PDE enzyme indicated lower amounts in affected than in control retinas in each age group studied. No differences were observed with the protein activator using ^{3}H-cyclic AMP as substrate (not shown).

Activity of cyclic GMP-PDE was then investigated in the presence of exogenous brain activator protein or EGTA (Fig. 2). The latter was used because Ca^{2+} is necessary for activator-induced increases in PDE activity. The addition of brain activator increased PDE activity in the 9-d control retina but added EGTA decreased activity (Fig. 2*a*). In the 9-d affected retina (Fig. 2*b*), the inhibitory effect of EGTA was also apparent, as was the stimulatory effect of brain activator. At about 5 and 7 weeks, neither brain activator nor EGTA had any marked effect on PDE activity in the control retina (Fig. 2*c*, *e*). In contrast, EGTA continued to exert an inhibitory effect in the dystrophic retina, and the addition of brain activator restored PDE activity to the levels seen in the control (Fig. 2*d*, *f*).

The expression of PDE activity in cells seems complex in that it can be regulated by several factors including activator protein and Ca^{2+} (refs 20, 21) in addition to the basic activity of the enzyme itself. It has been suggested[22] that the concentration of cyclic GMP in particular is controlled by a PDE protein activator. It was therefore not unexpected to find effects of activator and Ca^{2+} on cyclic GMP-PDE activity in 9-d control retinas. Morphologically, photoreceptor outer segments begin to develop at this time. However, it was surprising to find that after outer segment elongation and maturation added brain activator and Ca^{2+} had negligible effects on PDE activity in these retinas. This indicated that the activator-dependent PDE activity had switched to an activator-independent ('adult') type (Fig. 2). In contrast, in affected retinas, no such switch was found to occur as the outer segments began to develop. Exogenous activator markedly stimulated PDE activity throughout the 7-week experimental period, whereas endogenous activator levels fell to about half of that observed in control retinas. It is not known if endogenous activator levels are actually limiting in affected retinas. The finding that exogenous brain activator restores PDE activity to close to that seen in the control *in vitro*, however, could be important in future attemps to halt or at least slow the progress of the disease.

Table 1 Phosphodiesterase activity and protein activator activity in control and affected retinas

Animal age (day)	Animal type	Phosphodiesterase activity (pmol per mg protein per min)		Cyclic GMP-PDE activator concentration (units per mg protein)
		Cyclic AMP	Cyclic GMP	
9	Control	102	309	125
9	Affected	102	244	101
31	Control	104	887	53
34	Affected	104	326	23
48	Control	143	2,275	95
48	Affected	151	539	56

Phosphodiesterase activity was measured by determination of ^{3}H-nucleoside with an ion-exchange method (see text). Protein activator was determined in boiled retinal aliquots using purified bovine brain PDE which was deficient in activator. One unit of protein activator activity is that amount which is required to give half-maximal stimulation of the activator-deficient brain PDE enzyme. Values given are averages of triplicate determinations in two experiments which agreed to within 15%.

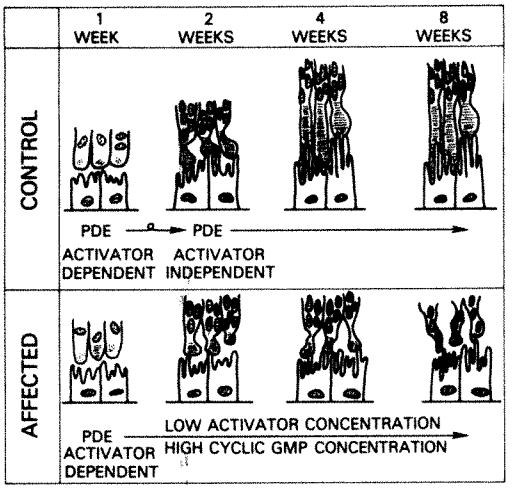

Fig. 3 Schematic outline of morphological and biochemical events in the development of outer segments (OS) in control and affected retinas. In both control and affected retinas, no OS are observed in the first postnatal week. OS appear in the second week, develop normally (4–5 weeks) in the control retinas but quickly degenerate in affected retinas. Biochemically, the cyclic GMP-PDE enzyme switches from an activator-dependent to an activator-independent type in control retinas but not in affected retinas. Protein activator concentration is substantially decreased in affected retinas.

It is well known that enzyme patterns change during development[23,24]. Recent evidence suggests that, at least in some tissues, PDE activity changes during differentiation with regard to its sensitivity to regulation by the Ca^{2+}-dependent protein activator[25,26]. Our data strongly indicate that a normal switch in PDE type fails to occur in affected retinas during photoreceptor development and that the low level of activator present in these retinas may not be sufficient to maintain adequate cyclic GMP-PDE activity (Fig. 3). It seems, therefore, that for the first time calmodulin can be directly linked to a disease process. It will be interesting to see if a similar situation exists in other degenerative diseases or if this biochemical defect is unique to inherited degeneration of the neural retina.

The dogs with rod–cone dysplasia were supplied by the National Retinitis Pigmentosa Foundation.

Evidence that cyclic GMP regulates membrane potential in rod photoreceptors

CYCLIC NUCLEOTIDES have been proposed as mediators of the decreased Na^+ permeability caused by illumination of vertebrate photoreceptors[1,2]. We show here that cyclic GMP depolarises the rod outer segment (ROS) approximately to the Na^+ equilibrium potential within milliseconds after being injected intracellularly, that previous light adaptation antagonises this depolarisation, and that the injection of cyclic GMP without illumination initiates a repolarisation after a time lag which is longer than that following a light flash and proportional to the injection time. The results are interpreted in terms of a model in which cyclic GMP levels are controlled by the resultant of cyclase and phosphodiesterase (PDE) velocities. The PDE velocity of hydrolysis in the dark is increased by prior light adaptation in the presence of increased substrate (cyclic GMP). The data suggest that cyclic GMP is an important factor in the regulation of the membrane potential of the ROS.

Biochemical experiments on the cyclic nucleotide system of isolated homogenised ROS suggest that illumination decreases the concentration of cyclic GMP by activating a GTP-dependent PDE[3,4]. The rate of light-initiated hydrolysis of cyclic GMP by PDE is apparently sufficiently fast to mediate the rapid initial decrease in Na^+ permeabilty[5,6]. The cyclic GMP that is not hydrolysed presumably increases Na^+ permeability. The mechanism of increased Na^+ permeability of the ROS plasma membrane would be by phosphorylating a membrane protein[6,7] as proposed for other tissues. Superfusion with cyclic GMP or a PDE inhibitor has been shown to depolarise rods[8]. We have injected cyclic GMP intracellularly through the recording pipette into ROS of the isolated retina of the toad, *Bufo marinus*, to determine the effects of excess cyclic GMP on membrane potential, latency and amplitude of the light response. We reported[9] that this excess cyclic GMP increases both the latency and amplitude of the response. Here, using the same preparation and methods, we found that excess injected cyclic GMP depolarised the rod membrane. This depolarisation in dark-adapted preparations frequently exceeded the zero level (Figs 1, 2) and attained a maximum value of +11 mV (Fig. 1*a*, *d*). A reversal potential of 0 to +10 mV was obtained for the isolated *Necturus* rod[10]. A value of +11 mV implies an intracellular Na^+ concentration ($[Na^+]_i$) of 66 mM, based on our extracellular concentration of 103 mM. This compares with 50 mM $[Na^+]_i$ estimated using another technique[11]. Therefore, +11 mV seems to approximate to the equilibrium potential for Na^+. The maximum depolarisation we observe is consistent with the interpretation that the injected excess cyclic GMP renders the ROS plasma membrane permeable to Na^+.

Intracellular injection of cyclic GMP in the absence of illumination should initiate a recovery from depolarisation after a time proportional to the amount injected, provided the dark concentration is less than the K_m of PDE which is 70 μM cyclic

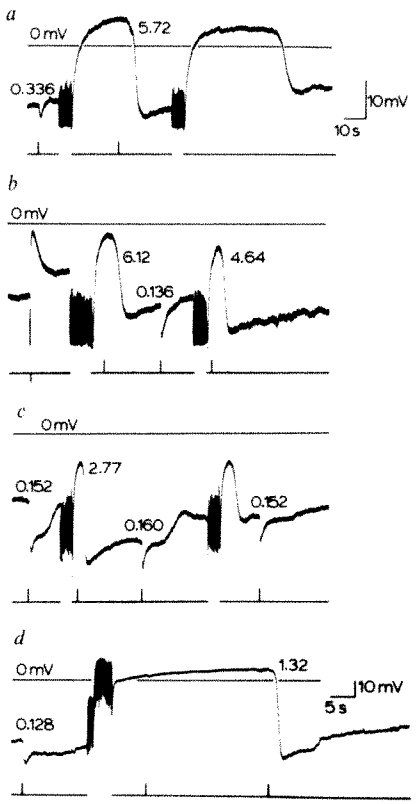

Fig. 1 Effects of intracellular injection of cyclic GMP in four different cells. Pen oscillations indicate injection of -2.5 nA; nominally 6×10^7 molecules cyclic GMP $nA^{-1}s^{-1}$ assuming transport number is 0.01. Numbers above membrane potential traces give latencies to light stimuli in seconds. All light flashes were 0.1 s, indicated by upward vertical lines on traces below each record. Light intensity is -3 log units on *A* and -2 log units for all other stimuli except the last on *D*, which is -1 log units. 0 log units = 5 $\mu W\,cm^{-2}$. Change in noise level during injection in *D* may be due to a pipette tip which broke in the cell, releasing a large amount of cyclic GMP such that the first stimulus after injection failed to elicit a response. However, note small deflection that may originate from outside the rod compartment (which is about 500 rods by electrical coupling[17,18]). Compartment size for cyclic GMP is not known.

GMP[4,5]. There are $5–10\times10^7$ molecules of cyclic GMP per ROS in the dark[12], or a concentration of 40–80 μM. The PDE should therefore be capable of higher velocities on injection of additional substrate. The V_{max} of PDE in the dark was estimated to be 10^4 times lower than in the light for frog ROS[5]. Nevertheless, a brief (40 ms) injection of cyclic GMP (Fig. 1*b*) causes an almost immediate depolarisation and a rapid repolarisation. Figure 2 shows that the time before repolarisation is proportional to the injection time. Each injection of additional substrate increases the PDE velocity, according to classical enzyme kinetics. The increased hydrolysis of cyclic GMP would tend to return the membrane potential to the baseline if cyclic GMP, acting through its kinase, determines membrane potential.

Following an intense flash (Fig. 3*a*) and after the baseline has returned to previous levels, injection of cyclic GMP fails to elicit

Fig. 2 Cell was dark adapted 10 min before injection; 2, 5 and 10 s injections of -2.5 nA, 25 mM cyclic GMP pipette.

a depolarisation. This suggests that light activation of PDE can potentiate the elevated velocity of PDE caused by additional substrate, thus preventing the depolarisation, or rapidly suppressing a brief depolarisation obscured by the pen oscillations. According to our model, the high V_{max} resulting from PDE light activation decays approximately with the time constant of dark adaptation (note no depolarisation after second injection, Fig. 3*a*, and small depolarisation 1 min later on, Fig. 3*b*). This persistently high V_{max} is unmasked by the injection of excess cyclic GMP in the dark.

Similar arguments may explain the length of latency, the increase in amplitude and the steeper repolarisation following a light flash delivered during the depolarisation after an injection of cyclic GMP. The light flash would briefly activate PDE, but the persistently high velocities of PDE caused by prior illumination and high substrate concentrations would be necessary for rapid hyperpolarisation of the membrane potential below the baseline. Illumination initiates hydrolysis by activation of PDE, but whereas the control hyperpolarisation in Fig 1*a* is complete in less than 0.5 s, the light-initiated PDE activity must have been augmented by increased substrate plus the light adaptation

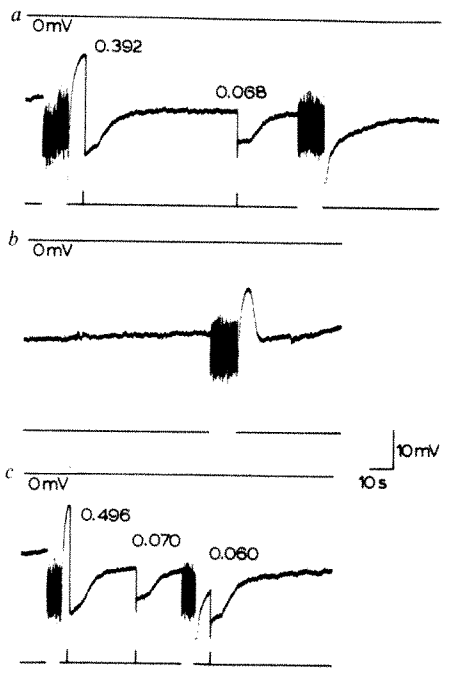

Fig. 3 *a*, *b* And *c* continuous recordings. Injections as in Figs 1 and 2, 25 mM cyclic GMP pipette. All light stimuli 0 log units.

effect mentioned above during the 5.72 s in which there is no visible response. The combination of increased substrate and light also seems to cause a persistent increase in PDE velocity, or undershoot, even after cyclic GMP levels are reduced, as judged by the increased plateau phase (Fig. 1*c*).

Figure 4 shows a control experiment in which the injection of the product of cyclic GMP hydrolysis, 5'-GMP, causes a small depolarisation. The response to illumination during this depolarisation is smaller than the control and of the same latency, in contrast to the opposite effects caused by cyclic GMP.

Excitation and adaptation of photoreceptors by light is a complex process that may involve molecules of the cyclic nucleotide systems, Ca^{2+} (refs 13–16) and other molecules. The experiments reported here are consistent with the interpretation that excess cyclic GMP injected into ROSs is capable of

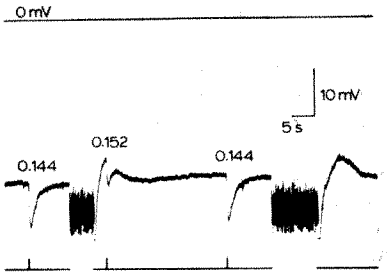

Fig. 4 Injections of −2.5 nA, 25 mM 5′-GMP pipette. Light stimuli −2 log units.

depolarising the rod plasma membrane to the Na^+ equilibrium potential, that both the injection and the previous adaptational history affect the intracellular concentration of cyclic GMP through the hydrolysing capacity of PDE, and that cyclic GMP must be hydrolysed by light-activated PDE so as to hyperpolarise the membrane to produce the normal response to illumination. These experiments suggest that normal intracellular levels of cyclic GMP may be an important determinant of the latency and other response characteristics of vertebrate rod photoreceptors.

We thank Ted Reid for helpful discussions. This work was supported in part by USPHS grant EY00089.

Note added in proof: Control experiments indicate that the zero level shown in the figures should be shifted upwards by 5 mV because of differences in tip potentials measured in Conway's and mock intracellular superfusates based on ref. 11.

Opposite effects of intracellular Ca^{2+} and glucose on K^+ permeability of pancreatic islet cells

MANY cells possess a potassium permeability system that is activated by an increase in the concentration of Ca^{2+} in the cytosol. This Ca^{2+}-sensitive permeability was originally described[1] and is best characterised[2] in erythrocytes, where its function is still not known. However, a similar mechanism could represent a physiological control of the membrane conductance in excitable tissues such as nerve[3,4] or cardiac muscle[5]. Physiological stimulation of salivary glands results in a Ca^{2+}-mediated release of potassium[6] and hyperpolarisation[7]. In contrast, glucose depolarises pancreatic B cells[8,9] by decreasing their potassium permeability[10,11], but also stimulates Ca^{2+} uptake by islet cells[12–14]. I report here an investigation into the possible interplay between these two effects of glucose. Evidence that intracellular Ca^{2+} increases the K^+ permeability in pancreatic islet cells and that the glucose-stimulated Ca^{2+} inflow may represent a feedback control of the glucose-mediated decrease in K^+ permeability of B cells is presented.

The K^+ permeability of pancreatic islet cells was evaluated by continuously monitoring the efflux of $^{86}Rb^+$ from preloaded isolated rat islets in a perifusion system[10,14,15]. The simultaneous measurement of $^{86}Rb^+$ and $^{42}K^+$ loss from islets labelled with both tracers has shown that the efflux of the more convenient isotope $^{86}Rb^+$ is a valid index of the qualitative changes in K^+ efflux from islet cells (data not shown).

A sudden rise in the extracellular Ca^{2+} concentration (0.5 to 10 mM) led to a reversible increase in the rate of $^{86}Rb^+$ efflux from islet cells perifused with a medium containing 3 or 6 mM

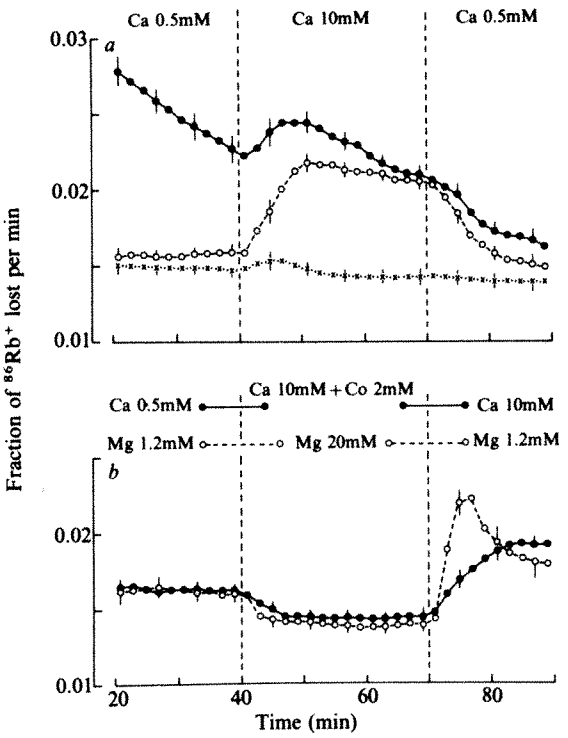

Fig. 1 Effect of a high concentration of extracellular calcium on rubidium efflux from perifused rat islets. *a*, Ca^{2+} concentration was increased from 0.5 to 10 mM between 40 and 70 min; glucose concentrations were kept constant at: ●, 3 mM; ○, 6 mM; ×, 10 mM. *b*, 2 mM Co^{2+} was added to the medium containing 10 mM Ca^{2+} (●), or the concentration of Ca^{2+} was kept constant (2.5 mM), while the concentration of Mg^{2+} was raised to 20 mM (○); the glucose concentration of the medium was constant at 6 mM. In (*a*) and (*b*), PO_4^{2-} was omitted to avoid precipitation of insoluble salts. Values are means ± s.d. of four experiments except in (*a*) where $n = 7$ at 6 mM glucose. Techniques have been detailed previously[10,14,15] and are only outlined below. Isolated rat islets were obtained by collagenase digestion of the pancreas of fed male Wistar rats. All experiments were carried out at 37 °C, with a Krebs–Ringer bicarbonate solution, *p*H 7.4, containing 6 mM K^+ and supplemented with 0.5% (w/v) bovine serum albumin. When Ca^{2+} was partially or completely omitted, it was replaced by Mg^{2+}; when its concentration was increased, Na^+ was isosmotically decreased. Groups of 60 to 90 islets were first incubated for 150 min in 0.5 ml medium containing 3 mM glucose and 0.2 mM $^{86}RbCl$ (350–480 mCi mmol^{-1}, Radiochemical Centre). After three washings with non-radioactive medium, the islets were placed in perifusion chambers[15]. $^{86}Rb^+$ was counted by measuring the Cerenkov radiation[10] in the effluent fractions, that were collected at 2 min intervals, and in the tissue at the end of the experiment. Results are expressed as fractional efflux of $^{86}Rb^+$.

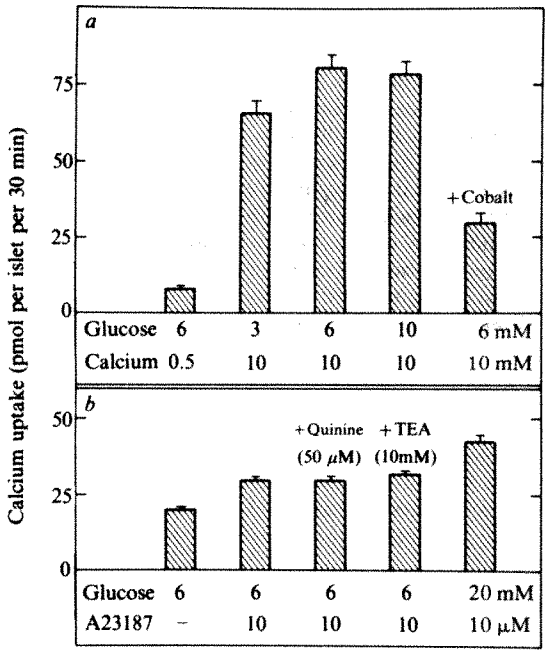

Fig. 2 Calcium uptake by islet cells. $^{45}Ca^{2+}$ uptake by rat islets was measured in relation to that of sucrose which is restricted to the extracellular space. The method has been described previously[14]. Islets were incubated in 100 μl medium layered on silicone oil and separated from the radioactive solution by centrifugation through the oil at the end of the 30-min uptake period. The radioactivity entrapped in the tissue pellet was counted by liquid scintillation. Blanks without islets did not differ from the background. *a*, After preliminary incubation for 40 min in the presence of 0.5 mM $CaCl_2$ and the same concentration of glucose as for the incubation period (3, 6 or 10 mM), batches of 10 islets were transferred into the prewarmed incubation medium. This phosphate-free medium contained the indicated concentration of glucose, 0.25 mM [6,6'-^{3}H]sucrose (0.1 Ci mmol^{-1}) and either 0.5 mM $^{45}CaCl_2$(60 mCi mmol^{-1}) or 10 mM $^{45}CaCl_2$ (3 mCi mmol^{-1}). In one series, 2 mM Co^{2+} was also present. Values are means ± s.e.m. of 14–17 batches of islets. *b*, After preliminary incubation for 40 min in the presence of 2.5 mM $CaCl_2$ and 6 mM glucose, batches of 10 islets were transferred into the incubation medium. The concentrations of A23187 and glucose were as indicated. The medium contained 2.5 mM $^{45}CaCl_2$ (12 mCi mmol^{-1}). Values are means ± s.e.m. of 12–16 batches of islets.

glucose, but not in the presence of 10 mM glucose (Fig. 1*a*). By contrast, increasing the Mg^{2+} concentration (1.2 to 20 mM) slightly depressed $^{86}Rb^+$ efflux (Fig. 1*b*), showing that the effect observed with Ca^{2+} is not due to damage of the cell membranes by a high level of divalent cations. The mere presence of 10 mM Ca^{2+} in the medium is not sufficient to increase the K^+ permeability of islet cells. Thus, $^{86}Rb^+$ efflux was not increased, but even somewhat decreased when the Ca^{2+}-antagonist[14], cobalt, was added to the medium simultaneously with the rise in extracellular Ca^{2+} (Fig. 1*b*). Figure 2*a* shows the increase in Ca^{2+} uptake that occurs in islet cells when they are transferred from a medium with a low (0.5 mM) to a medium with a high (10 mM) concentration of Ca^{2+}. Using this experimental protocol, it is difficult to know exactly what proportion of Ca^{2+} has been adsorbed or has entered the cells. Note, however, that only cobalt, and not 10 mM glucose, reduced Ca^{2+} uptake, although both conditions prevented the increase in $^{86}Rb^+$ efflux that is otherwise produced by the rise in extracellular Ca^{2+}.

To evaluate the role of intracellular Ca^{2+} in the activation of $^{86}Rb^+$ efflux further, the effects of the divalent cationophore A23187 (ref. 16) were studied. Addition of 10 μM A23187 to a medium containing Ca^{2+} steadily increased $^{86}Rb^+$ efflux in the presence of 6 mM glucose, but this effect was considerably reduced at 10 mM glucose (Fig. 3*a*). In the absence of extracellular Ca^{2+}, A23187 was almost ineffective, whereas the subsequent introduction of Ca^{2+} into the medium was followed by a prompt and marked increase in $^{86}Rb^+$ efflux, which was completely reversible when both A23187 and Ca^{2+} were withdrawn (Fig. 3*a*). It is thus clear that the ionophore, which has a weak affinity for monovalent cations[16], does not substantially transport Rb^+ ions from islet cells and that, again, Mg^{2+} cannot substitute for Ca^{2+} in activating K^+ permeability. The Ca^{2+}-activated K^+ permeability is specifically inhibited by quinine in the erythrocyte[2] and is sensitive to tetraethylammonium (TEA) in certain neurones[3]. Figure 3*b* shows that the increase in $^{86}Rb^+$ efflux brought about by A23187 + Ca^{2+} was reduced by TEA and stopped by quinine or 20 mM glucose. Only the effect of quinine was not reversible. In the presence of 6 mM glucose, A23187 produced a 50% increase ($P < 0.001$) in Ca^{2+} uptake by islet cells (Fig. 2*b*); this stimulation was unaffected by quinine or TEA and was increased by 20 mM glucose. Thus, the inhibition of Ca^{2+}-activated Rb^+ efflux by these agents is not due to a primary reduction of Ca^{2+} transport into the cells

Since islet cells[17,18], as most cells, possess an energy-dependent system to sequester Ca^{2+}, metabolic inhibitors should cause cellular organelles to release stored Ca^{2+} and increase the levels of the cation in the cytosol. Figure 4*b* shows that the rate of $^{45}Ca^{2+}$ efflux from perifused islets was augmented after addition of the mitochondrial uncoupler, dicumarol, and that this effect was unaffected by TEA or quinine. Dicumarol simultaneously increased the rate of $^{86}Rb^+$ efflux (Fig. 4*a*); TEA partially and reversibly prevented the increase, whereas quinine suppressed it almost completely. Omission of extracellular Ca^{2+} did not alter

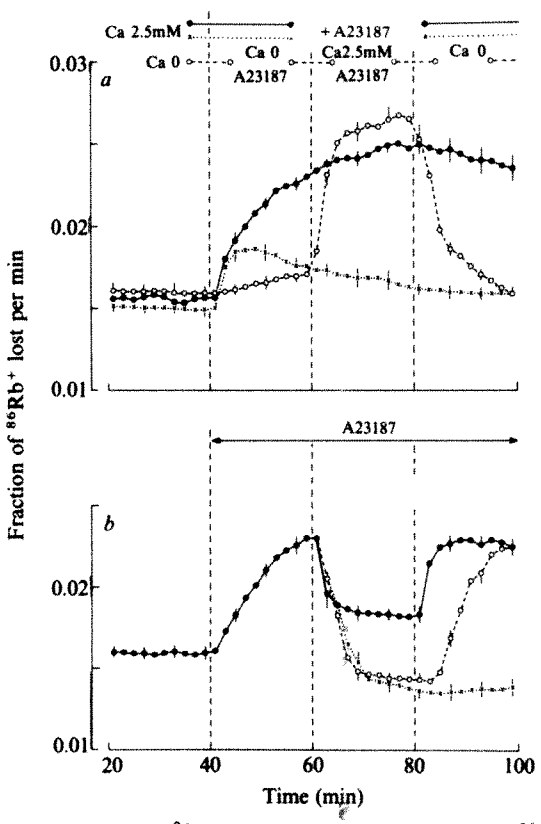

Fig. 3 Effect of Ca^{2+}-ionophore A23187 (10 μM) on $^{86}Rb^+$ efflux from perifused rat islets. Experimental procedure as for Fig. 1. Glucose concentrations: *a*, ● ○, 6 mM; ×, 10 mM; *b*, 6 mM. A23187 (Lilly) was disolved in dimethyl sulphoxide and the solvent was added alone (0.5%) in control solutions. In (*a*), A23187 was added from 40 to 100 min (● and ×) or 40 to 80 min (○); Ca^{2+} (2.5 mM) was present throughout or only between 60 and 80 min (○). Values are means ± s.d. of four experiments. In (*b*), Ca^{2+} was present throughout and A23187 from 40 to 100 min; between 60 and 80 min, TEA (●, 10 mM) or quinine (×, 50 μM) was added, or the glucose concentration was increased from 6 to 20 mM (○). Values are means ± s.d. of nine experiments until 60 min and of three experiments thereafter.

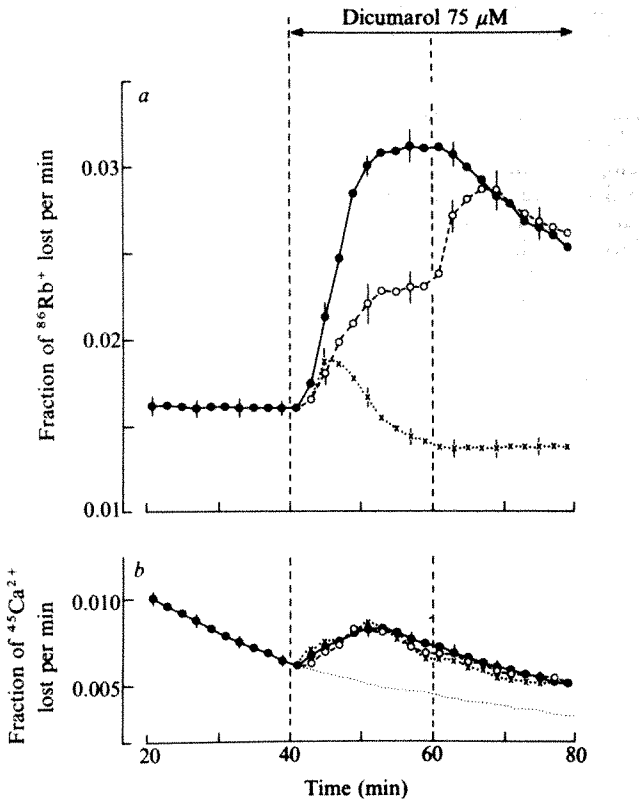

Fig. 4 Effect of dicumarol (75 μM) on $^{86}Rb^+$ (*a*) or $^{45}Ca^{2+}$ (*b*) efflux from perifused rat islets. Experimental procedure as for Fig. 1, except that for studying $^{45}Ca^{2+}$ efflux, islets were first incubated for 150 min in 0.5 ml medium with 1.25 mM $^{45}CaCl_2$ (200 μCi mmol^{-1}) and experiments were carried out in the absence of extracellular Ca^{2+}. Dicumarol (added from a 20 mM stock solution in 0.1 M NaOH) was present from 40 min onwards, while TEA (○, 10 mM) or quinine (×, 50 μM) was added between 40 and 60 min. The glucose concentration was constant at 6 mM. Values are means ± s.d. of nine experiments until 40 min and of three experiments thereafter.

the increase in $^{86}Rb^+$ efflux produced by dicumarol (not shown). Although a direct effect of dicumarol on the plasma membrane cannot be ruled out, these observations indicate that the activation of K^+ permeability by intracellular Ca^{2+} is not obligatorily linked to an influx of the divalent cation and are in keeping with the report[8] that uncouplers of oxidative phosphorylation hyperpolarise B cells.

The experiments described above strongly suggest that a rise in intracellular Ca^{2+} increases the membrane permeability to potassium in islet cells as in other tissues[1-6]. Although these experiments were made with whole islets comprising only two-thirds of B cells, the comparison of the changes in K^+ permeability with electrical recordings in B cells and with insulin release suggests physiological implications for our findings. When glucose is increased to a stimulatory concentration (>5 mM), the membrane potential of B cells first decreases from the resting potential to a constant threshold level and then starts to oscillate in slow waves[19]. These waves are the regular alternation of depolarisation phases with bursts of spikes and silent periods of repolarisation. The duration of these phases of activity increases with the concentration of glucose and is correlated with insulin release[19]. It is also known that the depolarisation from the silent to the active membrane potential[9,20,21] and perhaps also the spike activity[22] depend on the entry of Ca^{2+} into the cells. However, high concentrations of extracellular Ca^{2+} shorten the periods of depolarisation[20] and decrease insulin release[14,23]. On the other hand, TEA[24] and quinine[21] suppress the polarisation phases of the slow waves, thus producing continuous activity, and markedly increase insulin release[15,25]. In the light of these observations, this report supports the suggestion that an activation of K^+ permeability by Ca^{2+} may be involved in the hyperpolarisation which terminates the bursts of activity. Within this framework, glucose-stimulated Ca^{2+} uptake might seem irreconcilable with the prolongation of the phases of depolarisation. However, the key observation is that high glucose levels reduce or even suppress the Ca^{2+} sensitivity of that K^+ permeability system. Lew and Ferreira[26] have shown that the Ca^{2+} sensitivity of the potassium gating mechanism depends on the metabolic state of the erythrocyte. As glucose has to be metabolised by islet cells to control their K^+ permeability[10], the present system could represent a link between B cell metabolism and membrane permeability.

In conclusion, like the membrane of bursting neurones[3], the B cell membrane possesses a Ca^{2+}-activated K^+ permeability. Its glucose sensitivity makes the system a sensitive control mechanism of the periodical oscillations of the membrane potential and insulin release.

Variability of cell cycle times measured *in vivo* in embryonic chick retina by continuous labelling with BUdR

IN this report, cell cycle times were measured in the embryonic chick retina by continuous labelling with 5-bromodeoxyuridine (BUdR) and the fluorescence plus Giemsa[1] (FPG) technique. The measurement of cell cycle times in embryonic chick tissues *in vivo* is preferably carried out by continuous rather than pulse labelling because a single injection of a nucleotide precursor into an egg can form a long-lasting pool which remains available for at least 24 h (ref. 2). Continuous labelling with BUdR provides information about the number of S phases a metaphase cell has encountered since the start of labelling whereas the previous continuous labelling procedure[3] using tritiated thymidine indicates that a mitotic cell has encountered an S phase but does

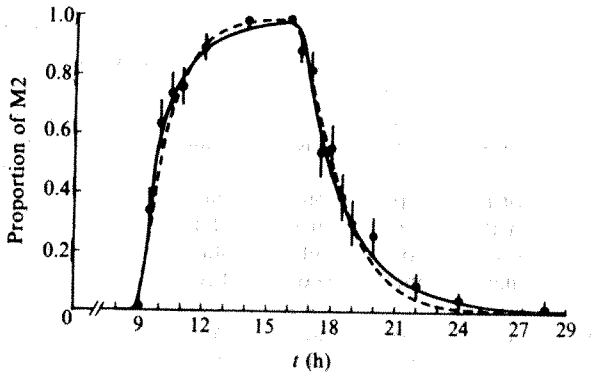

Fig. 1 The proportion of M2 at various times, t, after the start of labelling with BUdR. Each datum point (●) is the mean of five animals. Lines are drawn to 2 s.d. on either side of each datum point. 500 metaphase spreads were observed in each animal; the spreads which were not M2 at $t < 16$ h were either cells which had not incorporated BUdR or those which had incorporated it for one S phase; at $t \geq 16$ h, with very few exceptions they were cells which had incorporated BUdR for three or more S phases. To obtain these data, chick eggs incubated at 38 °C were injected at 72 h with 2×10^{-5} g BUdR and then sampled t hours later. Colchicine (1×10^{-5} g) was injected 1 h before sampling. Metaphase spreads were prepared from the neural retina as described previously[2]. For FPG, the spreads were stained in 1×10^{-4} g ml^{-1} 33258 Hoechst, mounted in 0.2 M sodium phosphate–citrate buffer, pH 7.2, and exposed to sunlight for 8–16 h, on successive days when necessary, and then stained in 3% Giemsa. The dose of BUdR was the lowest at which FPG differential staining could be achieved consistently. The continuous line is the curve of best fit obtained when the variances for phases SG_2EP and V were zero and when the phase G_1SAT (see text for definitions of these phases) was a constant plus a gamma distributed variable. The dashed line is the curve of best fit when G_1SAT was a constant plus an exponential variable. The curve for an inverse gaussian variable is not shown but it is close to that for the gamma.

not show how many. BUdR labelling thus gives more detailed data for estimating the means, variances and distributions of the durations of the cell cycle and its phases. Analysis of the data by statistical modelling has shown that the cell cycle is made up of a phase of constant duration and one of variable duration and we were able to test the appropriateness of different models for the variable phase. The variable phase was described well by a gamma distribution which was clearly not exponential in form and, somewhat less well, by an inverse gaussian distribution. A random transition in the cell cycle would be indicated by an exponentially distributed period; therefore, for the random transition model[4,5] of the cell cycle to hold, there would have to be an exponentially distributed component within the variable phase. Our results do not exclude this but they do show that such a component could only be a minor part of the variable phase.

The procedure was to inject BUdR into eggs, sample the retina after various times and prepare[2] metaphase spreads. Colchicine was injected 1 h before sampling. The number of metaphase spreads which showed incorporation of BUdR for: one or no S phases, two S phases and three or more S phases, were counted in each sample. These three types of spread could be identified[2] by the FPG technique because it stains unsubstituted and unifilarly substituted chromatids darkly and bifilarly substituted chromatids lightly. The data are presented in Fig. 1 as the proportion of metaphases which had incorporated BUdR for two S phases (M2 metaphases) at various times after the start of labelling.

To describe the statistical analysis of the data, it is necessary to divide the cell cycle in a non-conventional way. A line is drawn at a point in S, a second line is drawn in prophase and a third at the end of metaphase. The line in S marks the beginning of the minimum time a cell must spend in S so as to incorporate enough BUdR to be detectable by FPG when the cell has undergone another S phase. The line in prophase is at the beginning of the period during which the chromosomes could be rendered observable by the techniques for making metaphase spreads. This period is assumed to terminate at the end of metaphase. The new periods created by these boundaries were grouped as follows: G_1, the part of S following G_1 and the anaphase and telophase stages of mitosis were grouped together and called G_1SAT; the remainder of S, G_2 and a period approximating to early prophase were grouped and called SG_2EP; the period during which the chromosomes were observable was assumed to extend from about mid-prophase to the end of metaphase and was labelled V, for viewing period. For the analysis, the population of dividing retinal cells was modelled as an age-dependent branching process[6,7] up to the time at which cells were acted upon by colchicine. The population was assumed to be growing exponentially[7] from the time of BUdR injection and the parameters describing the population were assumed to remain constant from this time until the cells were collected. After colchicine began to act, it was assumed that all cells would be arrested in V. A parameter, c, known to be between 45 and 60 min (ref. 8), was introduced to denote the duration of colchicine action preceding t, the time of sampling. A theoretical curve for the proportion of V phase cells which were in M2 was derived as a function of t. This theoretical curve depended solely on c and the distribution of the durations of G_1SAT, SG_2EP and V and not on the individual distributions of G_1, S, G_2 and mitosis. This was why the phases of the cycle were grouped in the way described. Mathematical details of the analysis will be reported elsewhere[9].

The theoretical curve was fitted to the data using normal, gamma, displaced gamma or inverse gaussian (reciprocal normal) distributions for G_1SAT, SG_2EP and V. The parameters for the best-fitting curves and the value of c were found by minimising a weighted sum of squares by computer search methods. The best fit in the initial trials always occurred when the variances of SG_2EP and V were zero. In subsequent searches, therefore, SG_2EP and V were modelled as constants and different distributions were tried for G_1SAT. Neither the

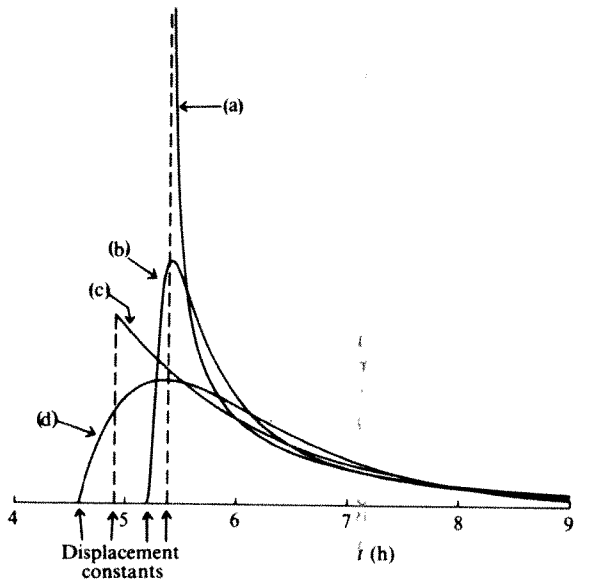

Fig. 2 Distributions for the variable phase in the cell cycle. Each curve is the probability density function obtained when G_1SAT was modelled by a displacement constant and a variable. The variables were: (a) a gamma with p unconstrained and estimated to be 0.44; (b) an inverse gaussian; (c) an exponential; (d) a gamma with p constrained to be 2; (a) gave the best-fitting theoretical curve and (b) was nearly as good; (c) was worse than either (a) or (b), and (d) gave a poorly fitting curve. The densities are markedly different for times less than 6 h both in shape and in the value of the displacement constant.

Table 1 Estimates of the cell cycle time

	Phase	Constant period (h)	Variable period (h) p	b	mean p/b	s.d. $p^{\frac{1}{2}}/b$	Total period (h) mean	median
Gamma	G_1SAT	5.4	0.44	0.34	1.3	2.0	6.7	5.9
	SG_2EP	1.7					1.7	1.7
	V	0.08					0.1	0.1
	Total cycle	7.2					8.5	7.7
Inverse gaussian	G_1SAT	5.2	0.48	0.30	1.6	2.3	6.8	6.0
	SG_2EP	1.7					1.7	1.7
	V	0.08					0.1	0.1
	Total cycle	7.0					8.6	7.8

The variable part of G_1SAT was modelled by a gamma density function

$$g(x) = b^p x^{p-1} \exp(-bx)/\Gamma(p) \qquad (x>0)$$

and an inverse gaussian density function

$$f(x) = \frac{p}{(2\pi b)^{1/2} x^{3/2}} \exp\{-\tfrac{1}{2}b(x-p/b)^2/x\} \qquad (x>0)$$

SG_2EP, V and the remainder of G_1SAT were constant. V is about 5 min (ref. 13); $c = 0.75$ h.

normal nor the gamma distributions alone gave good fits. The sum (convolution) of a normal distribution and an exponential distribution fitted best when the variance of the normal component was zero. This established that part of G_1SAT was also a constant. The fit was much improved when the variable part of G_1SAT was modelled by either the inverse gaussian or the gamma distribution instead of the exponential. The estimates for the cell cycle durations from the best-fitting curves are given in Table 1. The gamma distribution gave the best fit and for this the cell cycle time had a minimum of 7.2 h, a mean of 8.5 h and a standard deviation of 2.0 h.

These procedures show that SG_2EP, V and most of G_1SAT are constant in duration and constitute a constant phase in the cell cycle. The remainder of G_1SAT is variable and can be called the variable phase of the cell cycle.

The fit of the distributions assumed for the variable phase was assessed by the value of the minimised weighted sum of squares (WSS). The gamma distribution gave the lowest WSS and was thus the best fit. The inverse gaussian was nearly as good, with a WSS 1.24 times greater. The exponential distribution, on the other hand, gave a WSS 1.86 times that of the gamma. A more powerful test for the exponential distribution, because it is a special case of the gamma when the shape parameter p is equal to 1, was the value of p when a gamma distribution was assumed for the variable phase. We estimated $p = 0.44$ with an approximate standard error of 0.05 for the best-fitting theoretical curve. A value of $p = 1$ is thus approximately 11 standard deviations away from $p = 0.44$ and so it is very unlikely that our best-fitting curve had an exponentially distributed variable phase. The estimate of p shows that the total variability in cell cycle times cannot be attributed to a single random transition, nor can it be attributed to multiple transitions[10] because they lead to a gamma distribution in which p, equal to the number of transitions, is an integer ≥ 2 and this is further from the estimate of p.

The existence of a random transition in the cell cycle depends on whether the total variability can be partitioned into an exponential distribution and some other distribution. Computations showed that a gamma distribution with $p < 1$ cannot be partitioned in this way. Our inverse gaussian distribution can have an exponential component but the mean of the exponential cannot sensibly be more than 20% of the mean of the variable phase. Therefore, either the exponential component does not exist or it is small, and a decision as to which of these two is so rests on the power to discriminate between the gamma and the inverse gaussian; this depends in particular on data about the very shortest cell cycle times (Fig. 2).

The advantage of our method is that it gives more information about the distributions of subdivisions in the cell cycle than do methods[4,11] based on observations of total cell lifetimes. The latter methods have very little ability to distinguish between alternative distributions for periods in the cell cycle.

A gamma distribution with $p < 1$ does not have a simple mechanistic explanation. An inverse gaussian distribution can have a simple interpretation such as the time taken to reach the critical cell size at which division occurs[12].

The model used for the analysis of the data assumes that the cells were in a steady state of exponential growth from the time of BUdR injection. The assumption is justified because (1) there are several thousand cells in a chick retina at 3 days incubation and so the population would have been asynchronous, and (2) independent observations by us (unpublished) have shown that the parameters describing the population did not change between 3 and 5 days incubation. These observations were the frequencies of unlabelled DNA strands in metaphase chromatids of chick retinal cells after continuous exposure to BUdR between 3 and 5 days incubation. The frequencies agreed well with those predicted by the model and hence show that the assumption of a steady state from the time of BUdR injection is valid.

We consider our observations to have been made on a homogeneous collection of cells and not on a mixture of subpopulations of cells cycling at different rates. The possibility that cell cycle times change in succeeding generations has been excluded by the evidence referred to for steady-state conditions and so the mixture of generations which is present in the population could not be a source of subpopulations cycling at different rates. However, there could be subpopulations which remain steady with time and which each have an exponentially distributed variable phase. This would be a way of explaining our findings in accordance with the random transition model of the cell cycle, for, although it is easy to prove mathematically that a mixture of exponentials does not lead to a gamma distribution, it might be difficult with the present data to discriminate between a gamma and the distribution resulting from a mixture of exponentials. Even so, we know of no evidence to suggest that such subpopulations exist in an embryonic chick retina.

We have presented evidence that the variability in cell cycle times is derived from one part of the cell cycle only and it is therefore in this part of the cycle that the rates of cellular proliferation would be controlled.

Decreased response to calcitonin in osteopetrotic microphthalmic mouse bone

OSTEOPETROSIS is an autosomal recessive disease characterised by an increase in skeletal mass, often associated with retarded bone growth and a deficiency of marrow cavity development, which is related to a failure of bone resorption to keep pace with bone formation[1,2]. The disease has been studied in man and in several genetic mouse and rat mutants[1]. These mutants generally have diminished osteoclast function in the skeleton based on a lack of ruffled borders[1,3], lowered acid phosphatase activity[4] and a lower level of parathormone-induced resorption *in vivo*[3,5] and *in vitro*[6]. It seems that osteopetrosis has a cellular basis as it can be cured by parabiosis with a normal littermate[7] or by administration of spleen or bone marrow cells[8]. However, the only report examining bone cell metabolism in osteopetrosis indicates that in the calvarium of the osteopetrotic incisor-absent rat, parathormone affects adenylate cyclase activity and lactic acid production to the same extent as in the bone from normal littermates[9]. Recently, specific hormone-sensitive biochemical activities in intact bone in culture[10,11] or in cultured bone cells[12,13] have been associated with the functions of osteoclasts and osteoblasts. Based on these biochemical parameters we show here that in osteopetrotic (micropthalmic) bone there is a defect in calcitonin response attributable to osteoclast function whereas osteoblast activity is apparently normal.

The animals used in all experiments were obtained by breeding our own C57BL/6J +/mi parental stock. Eye pigmentation pattern at birth was used to identify genotype. Calvaria were excised aseptically from 1–2-day-old homozygous dominant normals (+/+) and recessive (*mi/mi*) osteopetrotics and were cultured in minimum essential medium (GIBCO) supplemented with 10% fetal calf serum and the hormones indicated in Table 1. Air containing 5% CO_2 was the gas phase for all experiments except the resorption studies in which 50% oxygen, 5% CO_2 and 45% nitrogen[10] was used. Cyclic AMP was measured by radioimmunoassay[14] using the ^{125}I-tyrosine methylester of succinyl-cyclic AMP and rabbit anti-cyclic AMP antiserum (both from NEN). Parathormone had a biological activity >2,500 U mg^{-1}, and was isolated in our laboratory[15].

The biochemical parameters chosen to test osteoclast function were the stimulation of cyclic AMP formation by both parathormone and calcitonin, and stimulation of hyaluronic acid synthesis by parathormone and the inhibition of this action by calcitonin. For osteoblast function the activities were stimulation of cyclic AMP formation and inhibition of citrate decarboxylation by parathormone—both effects are unaltered by calcitonin. To measure overall response of the osteopetrotic bone to parathormone nett resorption of the tissue was measured.

Parathormone stimulated resorption in normal calvarium by more than 50% and calcitonin blocked this response (Table 1). In osteopetrotic calvarium basal resorption was similar to that in the normals but bone resorption was not stimulated by parathormone. The basal level of cyclic AMP in the normal and osteopetrotic calvarium was the same (Fig. 1). Parathormone increased cyclic AMP production to the same extent in both groups as did prostaglandin E_2, another bone resorptive agent that apparently acts through cyclic AMP[16]. In contrast, calcitonin increased cyclic AMP more than 10-fold in the normal bones but only threefold in the osteopetrotic calvarium. Basal and parathormone-stimulated levels of hyaluronate synthesis were the same in both normal and osteopetrotic bones (Fig. 2). In normal bone calcitonin reduced this parathormone-stimulated increase by more than 75%. In osteopetrotic bone calcitonin exerted no inhibitory effect. Parathormone, as well as 1,25-dihydroxycholecalciferol, inhibited citrate metabolism in the osteopetrotic calvarium as effectively as in normal calvarium (Table 2).

These results show that osteopetrotic bone is deficient in certain biochemical markers that have previously been characterised in osteoclasts[12,13]. With the demonstration that the tissue fails to resorb normally under the influence of parathormone the results are consistent with the morphological and cytological evidence[1] that the genetic lesion resides in osteoclasts. In contrast, osteoblasts of osteopetrotic bone responded normally to parathormone and other bone resorptive agents (prostaglandin E_2 and 1,25-dihydroxycholecalciferol). This observation,

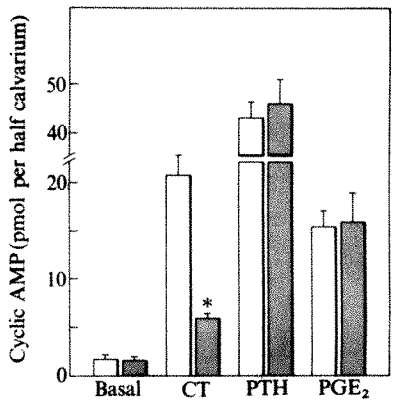

Fig. 1 The effect of calcitonin (CT, 12 nM), parathormone (PTH, 20 nM) and prostaglandin E_2 (PGE_2, 25 μM) on cyclic AMP formation in calvaria from normal and osteopetrotic mice. Half calvaria were placed in 1 ml of medium containing 0.5 mM theophylline and hormone additions as indicated. After 3 min cyclic AMP was extracted from the bones with 90% *n*-propanol[20] and was assayed by radioimmunoassay[14]. The dry weight and protein content of the normal and osteopetrotic were the same. Data are expressed as mean ± s.e.m. ($n = 4$). □, Normal (+/+); ▨, osteopetrotic (*mi/mi*). * Significantly different from normal, $P < 0.01$.

Table 1 Effect of parathormone and calcitonin on calcium release from normal and osteopetrotic calvaria

	Ca release (μmol per bone per 48 h)	
Treatment	Normal	Osteopetrotic
Control	0.271 ± 0.011	0.305 ± 0.008
Parathormone	0.414 ± 0.025*	0.335 ± 0.015
Parathormone + calcitonin	0.309 ± 0.008	0.330 ± 0.022

Whole calvaria (parietal and frontal bones) were individually cultured in 1 ml minimum essential medium containing 10% fetal calf serum. Parathormone (20 nM) and synthetic salmon calcitonin (12 nM, Armour) were added as indicated. Calvaria were maintained at 37 °C in a gas phase of 5% CO_2, 50% O_2, 45% N_2 for 48 h (ref. 10). Medium was removed and calcium concentration determined[19]. The release of calcium is defined as the difference between live bone and dead bone (frozen and thawed three times) for each group. Values are mean ± s.e.m.; $n = 7$ (for normal) and $n = 6$ (for osteopetrotic).

* Different from control, $P < 0.01$.

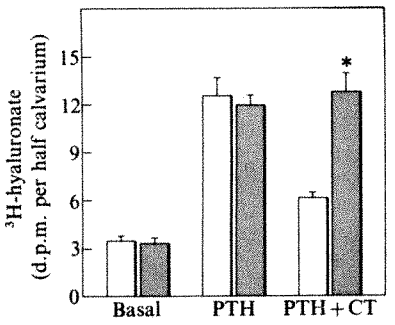

Fig. 2 Effect of parathormone (PTH, 20 nM) alone or in the presence of calcitonin (CT, 12 nM) on hyaluronic acid synthesis in half calvaria from normal and osteopetrotic mice. The bones were incubated for 24 h in medium (plus hormones as indicated) and then 3 μCi ^{3}H-glucosamine (NEN) was added to each bone. After 4 h the bones were rapidly frozen, digested with papain[11] and the ^{3}H-hyaluronic acid was isolated by differential cetylpyridinium chloride precipitation[21]. Data are expressed as mean ± s.e.m. (n = 6 for normal; n = 7 for osteopetrotic). Calcitonin alone had no effect on hyaluronic acid synthesis on either normal or osteopetrotic bone. □, Normal; ▨, osteopetrotic. * Significantly different from normal PTH + CT group, $P < 0.01$.

based on the degree of citrate decarboxylation[12,17], is consistent with that of Raisz *et al.*[6] who found that parathormone reduced collagen synthesis by osteopetrotic and normal bone by the same amount.

A paradoxical aspect of these findings is that whereas the osteopetrotic bone failed to respond to parathormone in terms of bone resorption, it exhibited normal response in terms of cyclic AMP formation and hyaluronate synthesis. It is possible that despite the seemingly normal activation of adenylate cyclase by parathormone, the specific response of the osteoclasts were nonetheless impaired. It has been shown that parathormone elicits substantially less cyclic AMP per osteoclast than per osteoblast[12]. This, together with the much larger number of osteoblasts than osteoblasts in calvarium[1], could have masked a decreased production of cyclic AMP by the osteoclasts. This is unlikely, however, as parathormone also increased the osteoclast marker hyaluronate synthesis to the same extent in osteopetrotic and normal bones.

The reduced response of osteopetrotic calvarium to calcitonin may be partly due to a decrease in the number of osteoclasts. Barnicot[18] reported that there was about a 30% reduction in osteoclast number in the grey lethal osteopetrotic mutant. However, the fact that the levels of basal and parathormone-stimulated hyaluronic acid synthesis in the microphthalmic bone were normal suggests that there was no difference in osteoclast number in our experimental conditions. It seems likely then that our results are better explained by a difference in the number or nature of calcitonin receptors, or an alteration in the mechanism for transmitting the calcitonin signal at the membrane level. The specific cause for such putative changes at the receptor level might be genetically based or secondary to alterations in circulating levels of calcitonin[22] or other agents that can affect bone function. Examination of receptor binding in the intact calvarium and in cells isolated from the osteopetrotic bone would help elucidate the nature of the genetic lesion.

Table 2 Effect of parathormone, 1,25-dihydroxycholecalciferol and prostaglandin E_2 on citrate decarboxylation in normal and osteopetrotic calvaria

Treatment	Citrate decarboxylation ($^{14}CO_2$ d.p.m. per half calvarium)	
	Normal	Osteopetrotic
Control	7,033 ± 1,383	7,305 ± 1,669
Parathormone	1,045 ± 114†	850 ± 107†
1,25-dihydroxycholecalciferol	1,675 ± 335†	2,091 ± 498*
Prostaglandin E_2	1,091 ± 173†	1,168 ± 351†

Calvaria were halved along the saggital suture and groups of 6 normal and 7 osteopetrotic half calvaria were individually cultured for each treatment group. Parathormone (20 nM), 1,25-dihydroxycholecalciferol (1 nM Roche) and prostaglandin E_2 (25 μM, Sigma) were added as indicated. After 48 h of culture the capacity of the bones to decarboxylate [6-^{14}C]citrate (NEN) was measured as previously described[10]. Data are shown as mean ± s.e.m.

* Different from control, $P < 0.05$.

Melittin shares certain cellular effects with phorbol ester tumour promoters

MELITTIN, a 26-amino acid polypeptide of known sequence, is the major constituent of bee venom[1]. Its primary amino acid sequence reveals that the molecule has both basic and hydrophobic termini, which give the molecule an amphipathic character. Consequently melittin can insert into phospholipid bilayers and exhibits surfactant activity. There is evidence that the association of melittin with cellular membranes results in: (1) disturbance of the acyl groups of phospholipids such that they

© Macmillan Journals Ltd 1979

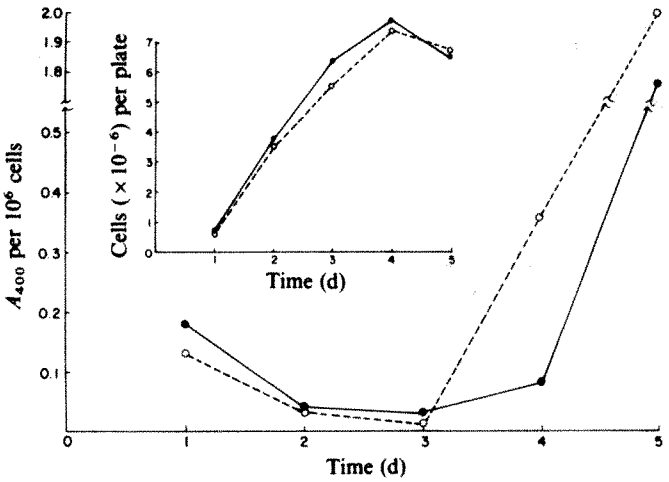

Fig. 1 The effect of melittin on the course of differentiation of C_3B16 melanoma cells. The cells were plated in medium containing 2 $\mu g\ ml^{-1}$ melittin in phosphate-buffered saline (PBS) or a control volume of PBS. After 24 h, fresh media containing either melittin or PBS were added. Cell counts and melanin determinations were carried out on replicate cultures every 24 h. The melanin content of cells plus medium was determined spectrophotometrically and is expressed in A_{400} units[17]. Cell number was determined with an electronic Coulter counter; inset shows total cell number per plate. All values are the means from three replicate culture plates; the s.e.m. was $\leq 10\%$ of the mean.

assume a broader range of angles with respect to each other[2,3]; (2) increased phospholipid susceptibility to hydrolysis by phospholipase[4,5]; and (3) increased synthesis of prostaglandins from the arachidonic acid released from the phospholipids[6]. Another amphipathic but structurally unrelated group of compounds consists of esters of the diterpene alcohol phorbol. These compounds are well known tumour promoters and have also recently been shown to have the ability to enhance phospholipid deacylation[7,19]. It is therefore of interest to determine whether melittin can produce some of the other phenotypic effects that can be induced in cells in culture by phorbol ester tumour promoters[8,9]. We report here that both melittin and the phorbol ester, 12-O-tetradecanoyl phorbol-13-acetate (TPA), inhibit differentiation of mouse melanoma cells, enhance anchorage-independent growth of adenovirus-transformed rat embryo cells, and induce arachidonic acid release and prostaglandin synthesis from C3H/10T½ mouse embryo fibroblasts.

Changes in arachidonic acid metabolism were examined in normal C3H/10T½ mouse embryo fibroblasts as it is known that *in vitro* transformation by chemical carcinogens or radiation is enhanced by TPA and related phorbol esters[10,11]. We found that TPA (2×10^{-8} M) and melittin (8×10^{-7} M) produced a two- to threefold enhancement of arachidonic acid and prostaglandin E_2 (PGE_2) release 3 h after addition to these cultures (Table 1). A low level of release of both arachidonic acid and PGE_2 in the control cultures was due to the presence of serum in the medium, an effect which has been previously reported[7,19]. Both TPA and melittin, however, enhanced arachidonic acid and PGE_2 release even in serum-free conditions. Time-course studies indicated that the release of both arachidonic acid and PGE_2 was maximal 3 h after adding either TPA or melittin. After 3 h the levels declined and had returned to control values by 24 h.

The phorbol esters are very potent inhibitors of differentiation in several cell culture systems (see ref. 9, for review),

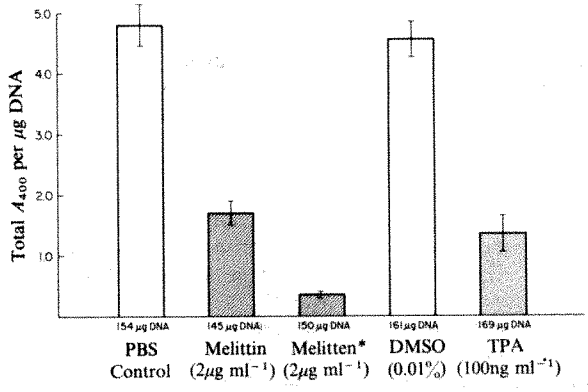

Fig. 2 The effect of melittin and TPA on the differentiation of C_3B16 cells. The cells were plated in medium containing melittin, TPA or the appropriate vehicle controls. After 24 h the cells were changed to fresh medium containing the appropriate compounds, except in one group (*) in which the melittin concentration was increased to 5 $\mu g\ ml^{-1}$. The cells and media were collected 5 d after plating. Melanin content of cells plus medium was determined spectrophotometrically[17], and the DNA content of the cells measured by the diphenylamine method[18]. Melanin levels are presented as the mean ±s.e.m. of determinations from four replicate culture dishes. DNA values are total μg per plate on day 5.

Table 1 Changes in arachidonic acid and prostaglandin release from C3H/10T½ cells

Addition	Arachidonic acid (c.p.m. $\times 10^{-3}$ per 200 μl medium)	Prostaglandin E_2 (c.p.m. $\times 10^{-1}$ per 200μl medium)
Phosphate-buffered saline	16 ± 2.0	28 ± 5.3
Melittin (8×10^{-7} M)	32 ± 3.7	68 ± 7.1
DMSO 0.1%	17 ± 1.5	25 ± 6.0
TPA (2×10^{-8} M)	40 ± 5.1	98 ± 11.0

C3H/10T½ cells (2×10^5) were grown for one day in 50-mm plastic tissue culture dishes in 4 ml of Dulbecco's modified Eagle's medium supplemented with 10% fetal calf serum. Then fresh medium containing 2.5 μCi of ^{3}H-arachidonic acid (60–100 Ci mmol^{-1}; NEN) was added. After labelling for 24 h this medium was removed and the cells were rinsed three times with 5 ml of serum-free medium. The labelled cultures were then incubated with 2 ml of medium containing 10% fetal calf serum and melittin, TPA or the corresponding solvents. Aliquots of the media were collected at 3 h and analysed for arachidonic acid and PGE_2 content by thin layer chromatography, as previously described[19]. The values given are means ± s.e.m. from three replicate culture plates. DMSO, dimethyl sulphoxide. Additional studies indicated that during the labelling period 90% of the incorporated ^{3}H-arachidonic acid was in cellular phospholipids and that the trace amounts of unincorporated radioactivity associated with the cells could not account for the radioactivity subsequently released into medium.

including melanogenesis in mouse melanoma cultures[12,20]. Cultures of the C_3 clone of B16 mouse melanoma cells (C_3B16) produce only small amounts of the pigment melanin until they reach confluence. There is then a marked and rather abrupt synthesis of melanin which accumulates in both the cells and culture medium.

Figure 1 indicates that when added to C_3B16 cultures shortly after plating, melittin (8×10^{-7} M) caused a delay of about 24 h in the onset of melanogenesis. Nevertheless, the melittin-treated cultures grew at the same rate and reached confluence at the same time as the control culture (inset Fig. 1). Thus, the delay in differentiation caused by melittin was not due to growth inhibition or cytotoxicity. These effects are similar to those produced by TPA and other phorbol-related tumour promoters[12]. Figure 2 compares in parallel the effects of melittin and TPA on pigment formation when either compound was added at the time the cells were plated. The amount of melanin was measured on day 5.

At 8×10^{-7} M (2μg ml^{-1}) melittin caused a 66% inhibition of pigment formation. An approximately equivalent inhibition was

Table 2 Enhancement of growth in agar of E11 cells by TPA or melittin

Compound added	No. of colonies	Agar cloning efficiency (%)
Control	58± 7.8	2.9±0.36
TPA (2×10^{-8} M)	192±22.8	9.6±1.14
Phorbol (3×10^{-7} M)	62± 8.4	3.1±0.42
Melittin (8×10^{-7} M)	174±16.8	8.7±0.84

Agar cloning efficiency of E11 cells was determined as previously described[15]. Cells 2×10^3 were suspended in 4 ml of Dulbecco's medium (0.1 mM Ca^{2+}, and 0.4% Noble Agar) supplemented with 7.5% fetal bovine serum. This suspension was overlaid on prehardened 4-ml base layers of 0.8% Noble Agar in the same medium in 50-mm culture plates. Parallel cultures contained TPA, phorbol or melittin incorporated in both agar overlay and base layers. Cultures were refed after 4 and 10 d by overlaying with medium containing 0.4% Noble Agar and the appropriate compounds. Colony number was determined by light microscopy after 14 d (colony size >0.1 mm). Results are reported as the average number of colonies in 4 replicate plates, ±s.e.m. and the agar cloning efficiency (%), ±s.e.m. Neither the solvents PBS or 0.1% DMSO affected cloning efficiency.

obtained with 1×10^{-7} M TPA (100 ng ml^{-1}). Increasing the melittin concentration to 2×10^{-6} M (5 μg ml^{-1}) one day after seeding produced a further inhibition of melanogenesis (Fig. 2). In these studies the DNA content of cultures was measured and the data obtained (Fig. 2) also indicate the absence of any growth inhibition by either melittin or TPA at the concentration used.

Phorbol esters have also been shown to enhance the expression of transformation-related properties in various cell cultures[8,9]. Growth of cells in soft agar (anchorage-independent growth) closely correlates with the tumorigenicity of cells *in vivo*[13]. Recent studies indicate that phorbol esters enhance the anchorage-independent growth of adenovirus-transformed rat embryo cells[9] and certain serially passaged mouse epidermal cells[14]. We examined, therefore, the effect of melittin on anchorage-independent growth of E11 cells, a clone of adenovirus-transformed rat embryo cells[15,16]. Table 2 indicates that both melittin (8×10^{-7} M) and TPA (2×10^{-8} M) caused approximately a threefold increase in the agar cloning efficiency of E11 cells, while phorbol, which is inactive as a mouse skin tumour promoter, did not enhance colony formation. Separate studies indicated that the concentrations of melittin and TPA used in these studies are approximately the optimal ones for these effects. Melittin concentrations greater than 2×10^{-6} M were cytotoxic.

The melittin preparation used in the above studies may contain trace amounts (~0.05 units per μg) of phospholipase A (Sigma) activity. This activity cannot, however, account for the results observed, as control studies using purified bee venom phospholipase A_2 (Sigma) in amounts several times higher than this level had no effect on melanogenesis by the B16 melanoma cultures, growth in agar of E11 cells, or PGE_2 synthesis.

Thus, it is rather striking that two structurally diverse compounds, melittin (a polypeptide) and TPA (a macrocyclic diterpene), have similar effects on three different properties of cells in culture: enhancement of the release of arachidonic acid and PGE_2; inhibition of melanogenesis; and enhancement of growth in agar. In view of the fact that melittin forms a very specific complex with the lipid phase of cell membranes[1-4], and the fact that a number of the early effects of TPA on cells are related to properties of cell membranes (see ref. 9 for review), it is likely that both compounds act by disturbing the structure and function of cell membranes. It is not clear, however, whether all the pleiotropic effects of the phorbol ester tumour promoters are secondary to such membrane effects or whether certain effects are mediated by non-membrane-related events. Melittin should prove highly useful for examining this question. In particular, it will be of interest to determine whether melittin itself has tumour-promoting activity. These studies are in progress.

Quantitation of the adaptive response to alkylating agents

ESCHERICHIA COLI can acquire resistance to the lethal and mutagenic effects of alkylating agents such as *N*-methyl-*N'*-nitro-nitrosoguanidine (MNNG)[1]. We have called this the adaptive response and have shown that it is distinct from previously described forms of DNA repair, including the inducible error-prone pathway[2,3]. The induction of a similar response has recently been demonstrated independently in the liver cells of animals fed dimethylnitrosamine (DMN)[4]. The phenomenon is therefore apparently widespread and may conceivably protect us from mutagenesis and carcinogenesis induced by low levels of nitrosamines. The main mutagenic lesion produced by agents like MNNG and DMN is probably O^6-methylguanine (O^6-MeG)[5], which can be read as adenine during DNA replication[6] and transcription[7]; certainly, most of the mutations produced by MNNG are GC to AT transitions[8]. Therefore, it was not surprising to find that adapted bacteria contain less O^6-MeG after a challenge dose of ^{3}H-MNNG than do non-adapted bacteria[9]. However, the response seemed to have two distinct components, which we can call the fast and the slow reactions. Immediately after a 2-min exposure to ^{3}H-MNNG the adapted bacteria contain less O^6-MeG, as if some fast reaction were protecting them from accumulating alkylation at the O^6 positions; there is, however, a limit to the capacity of this part of the response, and at higher concentrations of ^{3}H-MNNG (or after longer periods of exposure) the adapted bacteria start to accumulate O^6-MeG (and mutations) at the same rate as the non-adapted bacteria. This suggests that the molecules which carry out the fast reaction are used up during their interaction with O^6-MeG (that is, each can function only once). During subsequent growth in the absence of MNNG, both adapted and

50 μg ml^{-1} ^{3}H-MNNG	60 min, 0 °C	—	—	—	346	20,054	0.02

Cultures of *E. coli* AB1157 were challenged for 2 min at 37 °C with ^{3}H-MNNG (56 mCi mMol^{-1}) and then filtered, resuspended and either processed immediately or allowed to undergo outgrowth and then processed as described previously[9]. In each case, the c.p.m. in DNA O^6-methylguanine and N^7-methylguanine are for samples of $\sim 3 \times 10^{10}$ bacteria. The adapted bacteria had been exposed, before challenge, to 0.5 μg ml^{-1} MNNG for 90 min. For challenge of adapted bacteria in the presence of chloramphenicol (CM) the CM was added 10 min before challenge.

non-adapted bacteria lose their O^6-MeG, but the process is completed much sooner in the adapted bacteria; thus, there is apparently a slow component to the adaptive response. This separation of the response into two components[9] was supported by the observation that the fast reaction occurs at 0 °C whereas the slow reaction does not (P. F. Schendel and P.R., unpublished results). However, further experiments reported here indicate that these two reactions are different manifestations of a single, rather unusual form of repair.

Although adapted bacteria lose their O^6-MeG during outgrowth sooner than non-adapted, this proved to be mainly because the fast reaction had ensured that they contained less O^6-MeG at the start of the period of outgrowth. When the challenge doses of ^{3}H-MNNG were adjusted so that the adapted and non-adapted cultures were left with the same absolute amount of O^6-MeG, the two cultures lost it at the same rate (Fig. 1). Thus, adapted bacteria seemed to differ from non-adapted solely in the presence of the fast reaction, and the slow reaction seemed to be some constitutive form of repair that could not be enhanced by adaptation.

Having reached that conclusion, we were therefore surprised to find that mutants, selected for their inability to adapt to MNNG, were unable to carry out either the fast or the slow reaction[10]. The explanation became obvious, however, when we remembered that the fast reaction is carried out by gene products that have accumulated during the period of adaptation and are apparently used up during the challenge. The slow reaction therefore could simply be the induced synthesis and immediate action of the gene products that carry out the fast reaction; following challenge, such synthesis would be occurring at the same rate in adapted and non-adapted bacteria. If this were correct, the slow reaction should be inhibited by chloramphenicol and should not occur at 0 °C (or in adaptationless mutants); in contrast, the fast reaction should not occur if chloramphenicol has been present during the period of adaptation[1], but it could conceivably occur at 0 °C and should not be inhibited by chloramphenicol present during the challenge. These predictions were borne out by the experiments shown in Table 1.

Far from being complicated, the adaptive response to O^6-MeG seems therefore to be rather straightforward. If we accept that it is carried out by the product of the *ada* gene (in which we have isolated mutants)[10] and assume that each of these molecules can dispose of only one O^6-MeG, the numerology is approximately as follows. During growth in adapting concentrations of MNNG or during outgrowth following a challenge, each cell can make roughly 100 adaptation molecules per min, and so bacteria that divide every 30 min will contain about 3,000 molecules per cell when fully adapted. Any challenge that creates less than 3,000 O^6-MeG per cell can therefore be handled immediately by adapted bacteria, and no O^6-MeG will be detectable at the end of the challenge. During subsequent outgrowth, all O^6-MeG produced in non-adapted bacteria and any residual O^6-MeG in adapted bacteria (that is, in excess of 3,000) will be handled at the rate of 100 per min. These numbers are derived from the published experiments using *E. coli* AB1157 (ref. 9). Other strains we have studied have a more effective response and seem to make about five times more of the gene product.

The most unusual feature of adaptation is that the molecules which mediate the response seem to be used up during the reaction. This could explain why large doses of alkylating agents will inhibit the capacity of cells to handle subsequent small doses[9,11]. Furthermore, this feature may account for the discrepancy between the high carcinogenicity of certain nitrosamines and their low mutagenicity in the Ames test[12]; for reasons of economy, carcinogenicity is usually measured at fairly high dose rates at which the animal's adaptive response is

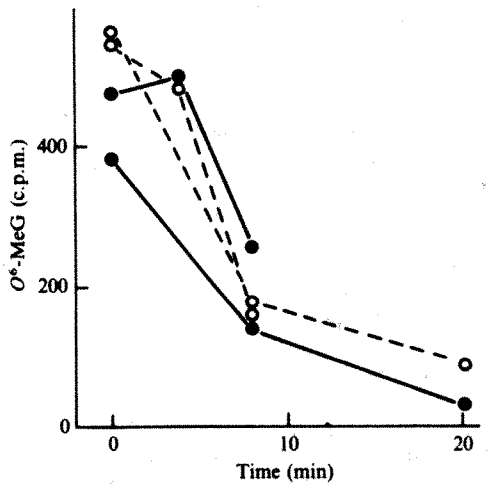

Fig. 1 The loss of O^6-methylguanine from the DNA of adapted and non-adapted *E. coli* AB1157. A culture was adapted by growth for 90 min in the presence of 0.5 μg ml^{-1} MNNG and then challenged with 50 μg ml^{-1} ^{3}H-MNNG for 2 min; to produce approximately the same starting level of O^6MeG, the control non-adapted culture was challenged with 10 μg ml^{-1} ^{3}H-MNNG. Both cultures were then filtered, resuspended and allowed to grow in the absence of MNNG. Samples containing 3×10^{10} bacteria were taken at various times and processed as described previously[9]. The results of two such experiments are shown. ●, Adapted bacteria; ○, non-adapted bacteria.

probably saturated, whereas bacterial mutagenicity is measured in growing cultures at low dose rates which are presumably within the capabilities of the bacterium's adaptive response.

Why the molecules that mediate adaptation can be used only once is not clear, but in this respect they resemble certain restriction enzymes which also can apparently act only once[13,14]. Fortunately, it is now possible to study the exact chemistry of the interaction between the mediator of bacterial adaptation and its substrate, O^6-MeG, because the process has been shown to occur *in vitro* (see accompanying paper[15]).

We thank Robert Kay for pointing out the similarity to restriction enzymes.

Adaptive response to alkylating agents involves alteration *in situ* of O^6-methylguanine residues in DNA

THE mutagenic lesion O^6-methylguanine (O^6-MeG) is slowly but actively removed from DNA in *Escherichia coli* cells treated with alkylating agents[1]. In bacteria exposed to sublethal concentrations of chemical mutagens such as *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) or *N*-methyl-*N*-nitrosourea (MNUA), an apparently error-free repair system is induced that confers increased resistance to the mutagenic and lethal effects of challenge doses of the same or related compounds[2–4]. This adaptive response is associated with an increased ability of the induced *E. coli* to remove O^6-MeG residues from their DNA (see ref. 5 and preceding paper[6]). We have investigated the action of cell-free extracts from adapted *E. coli* on DNA containing O^6-MeG residues. Here we report that O^6-MeG disappears from alkylated DNA after incubation with a crude enzyme fraction from adapted cells, although no concomitant release of the methyl group or the alkylated base or nucleotide occurs. Instead, this process is due to a previously unrecognised DNA repair mechanism involving enzyme-catalysed structural alteration of the alkylated residue.

The standard substrate used to study the removal of O^6-MeG from DNA *in vitro* is *Micrococcus luteus* DNA (chosen because of its high guanine content) alkylated with [*Me*-^{3}H]MNUA. Because the enzymatic release of free 3-methyladenine from the alkylated DNA by a DNA glycosylase[7] complicates the analysis of the fate of O^6-MeG residues, the MNUA-treated DNA was preincubated for 16 h at 80 °C in neutral solution. In this way, purines methylated in the 7 and 3 positions were released while the double-stranded DNA structure was maintained. After dialysis, about 75% of the radioactivity present in the DNA

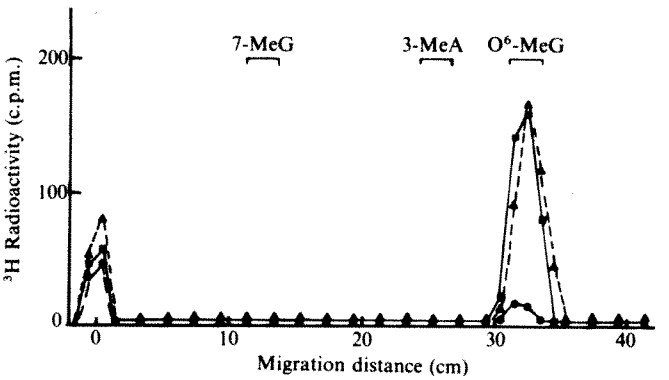

Fig. 1 Disappearance of O^6-methylguanine from DNA catalysed by extracts of adapted *E. coli*. *M. luteus* DNA (25 mg) in 5 ml of 0.2 M sodium cacodylate and 1 mM EDTA (*p*H 7.2) was incubated for 2 h at 37 °C with 1 mCi ^{3}H-MNUA (NEN, 1.03 Ci mmol^{-1}). The alkylated DNA was precipitated with 2 vols cold ethanol, dissolved in 5 ml of 0.1 M NaCl, 10 mM sodium citrate and 10 mM potassium phosphate (*p*H 7.4), and dialysed at 4 °C for 24 h against the same buffer. The DNA solution was then incubated at 80 °C for 16 h in a sealed glass ampoule, followed by dialysis at 4 °C for 24 h against 1 M NaCl, 10 mM Tris-HCl and 1 mM EDTA (*p*H 8.0), and for 4 h against the same buffer without NaCl. The DNA was stored frozen and had a specific radioactivity of 50,000 c.p.m. per mg. *E. coli* B/r was grown and adapted by exposure to MNNG (1 μg ml^{-1} for 90 min) as described by Jeggo *et al.*[3]. Adapted or non-adapted cells (3 g) were disrupted by grinding with three parts of sea sand and extracted with 12 ml of 70 mM HEPES-KOH, 1 mM dithiothreitol and 5% glycerol (*p*H 7.8). After removal of debris by centrifugation, extracts contained about 25 mg protein per ml. They were stored in small aliquots at −70 °C and were never refrozen. The reaction mixture (30 μl) contained 70 mM HEPES-KOH (*p*H 7.8), 1 mM dithiothreitol, 1 mM EDTA, 50 μM spermidine, 5% glycerol, 12 μg (600 c.p.m.) heated ^{3}H-MNUA-treated DNA, and cell extract (2 μl). After 10 min at 37 °C, the reaction was stopped by chilling to 0 °C and addition of 30 μl cold 0.8 M trichloroacetic acid. After 10 min at 0 °C, the mixtures were centrifuged at 10,000*g* for 15 min. The supernatant solutions, which contained less than 5% of the total radioactivity, were discarded. The precipitates were suspended in 30 μl 0.1 M HCl, supplemented with carrier O^6-methylguanine (30 μg in 3 μl H_2O), and the DNA was hydrolysed at 70 °C for 30 min. Each hydrolysate was applied to Whatman 3MM paper and chromatographed for 20 h in isopropanol/concentrated NH_3/H_2O (7:1:2). Reference methylated purines[7] were run in separate lanes and localised as UV-absorbing material. Strips containing individual samples were cut out and then cut transversely into 1-cm pieces. Each such piece was cut into small fragments, which were transferred to a scintillation vial and eluted with 2 ml H_2O. Radioactivity was determined after addition of 15 ml of Triton X-based scintillation fluid. Reaction mixtures contained no extract (▲), extract from non-adapted cells (■) or extract from adapted cells (●).

was in the form of O^6-MeG residues (Fig. 1). The residual radioactive material may be ascribed to the presence of alkylated pyrimidine nucleotides and phosphotriesters[8].

Incubation of this DNA substrate with crude cell extracts of *E. coli* B/r, adapted by growth for 90 min in the presence of 1 μg ml^{-1} MNNG (ref. 2), results in the disappearance of O^6-MeG residues from DNA. In the same conditions, extracts from non-adapted bacteria show no detectable activity. The method of assay involves incubation of the alkylated DNA with cell extract in an EDTA-containing reaction mixture, followed by precipitation of the DNA with cold ethanol or dilute trichloroacetic acid. After mild acidic hydrolysis of the precipitate to release free purines, paper chromatography of the hydrolysate is used to determine the amount of radioactivity co-migrating with authentic O^6-MeG (Fig. 1). With increasing amounts of adapted cell extract in the reaction mixtures, decreasing amounts of O^6-MeG are recovered (Fig. 2).

The method of assay clearly demonstrates the disappearance of O^6-MeG from DNA, but an additional striking feature of the reaction is that no radioactive material is released in an ethanol- or acid-soluble form at the end of the incubation period. In conditions where 90% of the radioactive O^6-MeG has been altered or removed, less than 5% of the total radioactivity is released in soluble form. On mild acidic hydrolysis of the precipitated DNA, using conditions allowing essentially quantitative release and recovery of O^6-MeG (ref. 1), the radioactivity associated with the enzymatically altered residues is converted into volatile form. Thus, the radioactive material is

0028-0836/79/270076—02$01.00

© Macmillan Journals Ltd 1979

retained in the acid hydrolysate but is lost on evaporation or after application of the sample to a chromatography paper. Similar results have been obtained with DNA alkylated with either [*Me*-^{3}H]MNUA or [*Me*-^{14}C]MNUA, and a volatile secondary product (presumably methanol) is generated by acid treatment in either case. These data indicate either that the methyl group bound at the O^6 position of guanine is transferred to another site by the activity in adapted *E. coli* cells, or that O^6-MeG residues are destroyed (for example, by ring cleavage) without being released from DNA. Further, the enzymatically altered base residue is more acid labile than intact O^6-MeG.

The radioactive material present in reaction mixtures treated with adapted cell extract (90% disappearance of O^6-MeG from DNA) was not liberated in ethanol-soluble form (<10% release) by treatment with either Pronase (2 mg ml^{-1}) or pancreatic RNase (100 μg ml^{-1}) for 4 h at 30 °C. On the other hand, treatment with pancreatic DNase I (100 μg ml^{-1}, 0.005 M each of $MgCl_2$ and $CaCl_2$ added) for 4 h at 30 °C resulted in the conversion of more than 80% of the radioactivity into ethanol-soluble form. Similar results were obtained in control experiments with DNA incubated with non-adapted cell extract. Thus, the radioactive methyl groups in the ethanol-precipitable material generated from O^6-MeG residues by treatment with an extract from adapted *E. coli* remain in DNA and do not seem to be transferred to a protein or RNA molecule.

These data differ from previous reports on the fate of O^6-MeG residues in DNA after treatment with crude enzyme fractions. Kirtikar and Goldthwait[9] claimed that a DNA glycosylase activity that would release free O^6-MeG from alkylated DNA was present in a partly purified preparation of *E. coli* endonuclease II. However, an extensive search with different enzyme fractions from either non-adapted or adapted *E. coli* has failed to confirm the existence of such a DNA glycosylase (ref. 7 and our unpublished data). Pegg[10] showed that rat liver extracts can remove O^6-MeG from alkylated DNA, albeit about 1,000 times less effectively than the adapted *E. coli* extracts investigated here. The removal was not due to a DNA glycosylase, and the active enzyme was tentatively identified as a demethylase because part of the radioactivity from the substrate could be recovered as free methanol after prolonged incubation with the cell extract.

E. coli K-12 mutants defective in the adaptive response (*ada*) have recently been isolated[11]. We have analysed extracts from two such mutants, *ada*-5 and *ada*-6, and their *ada*$^+$ parent strain AB 1157, for their ability to alter O^6-MeG residues in DNA. Extracts (10–40 μg protein added to the standard reaction mixture) from both mutants were unable to cause the disappearance of detectable amounts (<10%) of O^6-MeG from alkylated DNA even though the bacteria had been pretreated with MNNG, whereas the parent strain extract was clearly active. However, as *E. coli* K-12 yields a somewhat weaker adaptive response than *E. coli* B (refs 4, 6) the extract (40 μg protein) from the *ada*$^+$ strain only caused the loss of 60% of the O^6-MeG residues. Growth rates in the conditions of adaptation were similar for both the parent and mutant strains. These data strongly indicate that the enzyme acting on O^6-MeG residues investigated here is related to the previously characterised repair pathway of adaptation *in vivo*. The simplest interpretation of the available results is that this inducible enzyme is the product of the *ada*$^+$ gene in *E. coli*.

There has been only preliminary characterisation of the properties of the *E. coli* enzyme activity associated with the adaptive response. The activity remains in the supernatant of crude cell extracts after precipitation of nucleic acids (and some proteins) with 0.8% streptomycin sulphate, and it can be recovered by precipitation between 1.6 M and 2.6 M ammonium sulphate followed by dialysis. It is heat labile (50% inactivation occurring after 1 min at 45 °C in the standard reaction mixture without DNA) and is partly inactivated by freezing and thawing. There is no apparent cofactor requirement of the ammonium sulphate-fractionated enzyme, and no detectable stimulation of activity by Mg^{2+} or ATP. Inclusion of spermidine (5×10^{-5} to 2×10^{-4} M) in the assay mixture results in slight (about twofold) stimulation of activity.

Although the present results show that O^6-MeG removal in adapted *E. coli* does not occur by nuclease, glycosylase or demethylase action, the precise nature of the enzymatic alteration of this alkylated residue remains unclear. The methyl group might be transferred to another, biologically less hazardous, site in DNA. However, the present data exclude methyl group transfer to the N^7 position of guanine, because no 7-methylguanine or any other acid-stable product is generated (Fig. 1). Alternatively, the miscoding O^6-MeG might be converted to a non-coding residue, such as by cleavage of the pyrimidine ring to generate a substituted imidazole residue remaining bound to DNA. Methyl-group transfer or ring-opening of the alkylated residue might also result in a lesion more readily recognised by other DNA repair enzymes. It is now of interest to define the structural alteration of O^6-MeG that occurs in adapted *E. coli*, and this will depend on the availability of suitable methods to release and purify the labile altered residues from enzyme-treated alkylated DNA.

We thank John Cairns for helpful discussions, Penelope Jeggo for providing us with *E. coli ada* mutants, and Anita Jacobsson for technical assistance. This work was supported by the Swedish MRC. P.K. was the recipient of an EMBO fellowship (1977–79).

Hormonally specific phosphorylation of cardiac troponin I and activation of glycogen phosphorylase

WE recently reported that PGE_1 and isoprenaline have very different effects on the substrates of cyclic AMP-dependent protein kinase that regulate cardiac glycogen metabolism. Both agents elevated the cyclic AMP content and the protein kinase activity ratio in isolated perfused rat hearts, but only isoprenaline caused changes in the activity of the substrates of protein kinase (presumably phosphorylation, causing activation of phosphorylase kinase and inactivation of glycogen synthase)[1,2]. Thus, the activation of soluble protein kinase appears insufficient to cause alteration of the regulatory enzymes of glycogen metabolism. This suggests that the glycogenolytic responses to isoprenaline involve actions other than the activation of soluble protein kinase. We now report the effects of PGE_1 and isoprenaline on another substrate of protein kinase, the inhibitory subunit of cardiac troponin (TNI). Since the phosphorylation of TNI may mediate the positive inotropic effects associated with β-adrenergic stimulation and cyclic AMP accumulation[3], we felt that the hormonally specific expression of protein kinase activity might be used as a tool to determine whether similar specificity applies to the phosphorylation of TNI and to establish the functional relevance of that phosphorylation.

Although no biochemical consequence of TNI phosphorylation has been found to explain the positive inotropic action of drugs, some correlative data suggest a role for phosphorylation of TNI in the regulation of myocardial contractility. Cardiac TNI is phosphorylated in perfused hearts following exposure to β-adrenergic agonists and the phosphorylation correlates well with the time course and concentration-dependence of enhanced contractility[3]. When purified cardiac troponin is incubated with cyclic AMP-dependent protein kinase and [γ-^{32}P]ATP, the rate of phosphorylation is stimulated by cyclic AMP and inhibited by the heat stable inhibitor of protein kinase. The ^{32}P is incorporated specifically into the TNI subunit at rates two- to threefold greater than into mixed histones[4]. These results suggest that the rapid and specific phosphorylation of the I subunit of troponin may be a consequence of cyclic AMP accumulation in cardiac muscle. However, it is not clear whether phosphorylation of TNI always follows from elevation of intracellular cyclic AMP or results only from β-adrenergic stimulation[3,5]. Accordingly, we have compared the effects of isoprenaline and PGE_1 on cyclic AMP content, protein kinase activity, the phosphorylation of TNI, and contractility in the isolated perfused rat heart.

Measurement of the phosphate content of TNI depends for its accuracy on the purity of the material isolated from the perfused hearts. A densitometer tracing of a gel electrophorogram of the material isolated by affinity chromatography over troponin C columns (Fig. 1) shows that the major band of protein (>90%) moved with an apparent molecular weight of 26,100, in good agreement with the published value for TNI from other laboratories[3,4]. The purification by affinity chromatography and homogeneity with appropriate mobility on SDS-polyacrylamide gel electrophoresis are good criteria supporting the identity of the isolated protein as TNI. Small amounts of impurities (<10%) occasionally noticed on electrophorograms showed mobilities corresponding to those of TNC and TNT troponin subunits.

Both isoprenaline and PGE_1 increased the cyclic AMP content and the activity ratio of protein kinase in perfused rat hearts (Table 1). The activation of protein kinase occurred without changes in total activity (that measured in the presence of 2 μM cyclic AMP). Only isoprenaline treatment increased the phosphate content of TNI, and caused activation of phosphorylase and an enhanced rate of ventricular pressure development. PGE_1 did not show these effects despite its capacity to stimulate accumulation of cyclic AMP. The effects of 10 nM isoprenaline and 30 μM PGE_1 on cyclic AMP accumulation and protein kinase activation were additive, whereas the activity ratio of phosphorylase and the degree of phosphorylation of TNI were the same following treatment with isoprenaline alone and with the combination of isoprenaline and PGE_1.

We have found, like England[3], that treatment of perfused rat hearts with isoprenaline increases the phosphate content of TNI. Our values were up to 0.8 mol phosphate per mol TNI, in reasonable accord with the values reported by England for perfused rat heart[3] and comparable to values for perfused mouse heart[6]. These measurements are lower than the phosphate content of TNI prepared from rabbit heart (1–1.9 mol phosphate per mol TNI) as reported by Perry and co-workers[7,8] but are in good agreement with the *in vitro* experiments of Stull and Buss[4] who, using purified components, found that cyclic AMP-dependent protein kinase catalysed the maximal incorporation of 1 mol phosphate per mol TNI, suggesting a single site available for phosphorylation per TNI molecule. However, we emphasise the relative changes in TNI phosphate and the failure of PGE_1 to cause TNI phosphorylation.

Previous reports have demonstrated that not all changes in cardiac contractility correspond to an altered phosphorylation state of TNI. For instance, England[3] found that the inotropic effect of glucagon was maximal before significant TNI phosphorylation could be detected. Ezrailson *et al.*[9] reported that in perfused cat heart ouabain, increased frequency of stimulation, and elevated external calcium induced positive inotropic responses with no changes in TNI-phosphate. Frearson *et al.*[10] found no change in TNI phosphorylation when the inotropic state of perfused rabbit heart was altered by low-sodium and

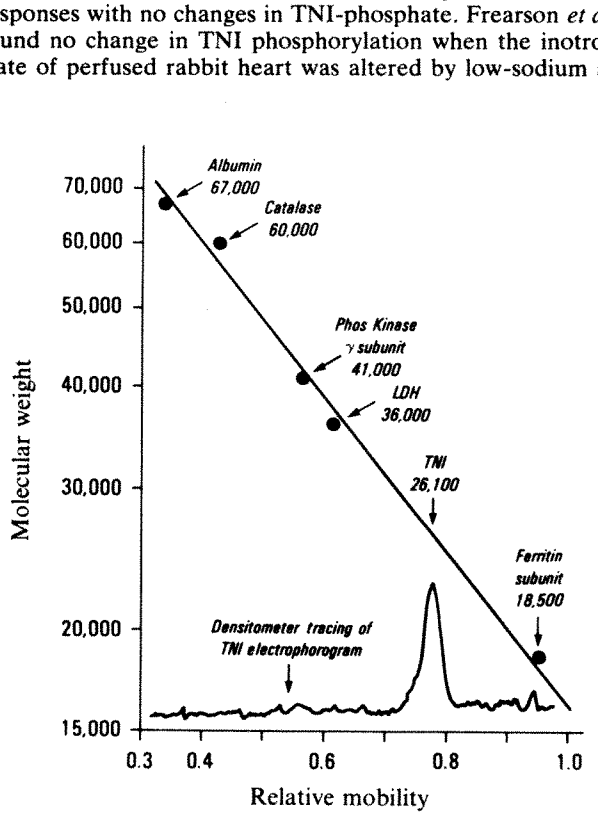

Fig. 1 SDS-polyacrylamide gel electrophoresis of TNI and calibrating proteins. Samples were solubilised as described by Stull and Buss[4]. Samples and standards (Pharmacia) were applied to 0.75 × 100 mm gel consisting of a 3.3% stacking gel and a 7.0% separating gel containing 0.5% SDS with Tris-glycine-SDS reservoir buffer. Following electrophoresis, gels were stained with Coomassie blue R (0.15%) in aqueous methanol (50%) acetic acid (7%), then destained with methanol acetic acid and equilibrated with acetic acid (7%). Stained bands were located and quantified by integration of areas under peaks of densitometer scans. The main figure shows a calibration curve (log of molecular weight versus mobility) indicating an apparent molecular weight of 26,100 for rat cardiac TNI. The inset shows actual densitometer tracing of gel with 2 μg of rat TNI applied. Purity of >95% was observed when up to 100 μg of TNI were applied.

Table 1 Effects of isoprenaline and PGE_1 singly and in combination

Treatment (n)	Cyclic AMP (pmol per mg protein)	Protein kinase (−cAMP: +cAMP)	Phosphorylase (−AMP: +AMP)	Phosphate content of TNI (mol per mol)	dP/dt
Control (7)	5.0 ± 0.2	0.17 ± 0.01	0.05 ± 0.02	0.34 ± 0.03	1.00
INE (10 nM) (7)	8.6 ± 0.5**	0.26 ± 0.01**	0.36 ± 0.02**	0.49 ± 0.04**	1.83**
INE (100 nM) (5)	—	0.39 ± 0.01**	0.58 ± 0.03**	—	2.20**
PGE_1 (30 μM) (6)	7.3 ± 0.3**	0.24 ± 0.02**	0.08 ± 0.03	0.38 ± 0.06	0.94
INE (10 nM) + PGE_1 (30 μM) (6)	11.2 ± 0.7**	0.33 ± 0.01**	0.34 ± 0.03**	0.53 ± 0.07*	1.77**
INE (100 nM) + PGE_1 (30 μM) (4)	13.1 ± 1.1**	0.41 ± 0.02**	0.58 ± 0.03**	0.51 ± 0.05**	2.10**

Values are mean ± s.e.m. Asterisks indicate values differing significantly from control values by unpaired t-test analysis (*, $P < 0.02$; **, $P < 0.005$). dP/dt is expressed as a fraction of mean control value (1,680 ± 60 mm Hg s^{-1}). Hearts were excised from heparinised (1,500 U per kg), anaesthetised (pentobarbital, 100 mg per kg) male Sprague–Dawley rats (200–300 g) and immersed in ice cold saline until beating ceased. Hearts were perfused at 32 °C via the aorta without recirculation at an aortic pressure of 60 mm Hg with Krebs–Henseleit buffer as described by Neeley[17]. Mean coronary flow was 8 ml min^{-1}. Hearts were paced at 240 beats per min and equilibrated for 30 min before treatment. Left ventricular pressure and its rate of development (dP/dt) were monitored using an intraventricular needle connected to a pressure transducer. Following a 2-min perfusion with buffer containing drug or vehicle, hearts were frozen with Wollenberger clamps cooled in liquid N_2. The atria and great vessels were trimmed away and the remainder pulverised in a percussion mortar cooled in liquid N_2. The powder was stored at −70 °C until assayed. Cyclic AMP purified from acidic extracts of frozen tissue powder was quantified by the Gilman protein binding assay[18]. Protein kinase activity was assayed in the 300,000 g supernatant of a 1 : 10 homogenate of frozen tissue powder by the method of Keely *et al.*[19]. The activation state of protein kinase is expressed as the ratio of activities measured in the absence and presence of 2 μM cyclic AMP. Glycogen phosphorylase activity was assayed fluorometrically[20]; activities are expressed as the ratio of activities assayed in the absence and presence of 2 mM AMP. We have previously described these assays in more detail[2]. TNI was purified by troponin C affinity chromatography as described by Syska *et al.*[21] on TNC columns. For this procedure, 500 mg of frozen heart powder were homogenised in the presence of 8M urea which was removed only after the TNI was purified, so that enzymatic modification during purification was minimised[3]. The yield was ~120 μg TNI per g heart and was independent of the extent of phosphorylation. Purity of TNI was ≥90% as established for each sample by SDS polyacrylamide electrophoresis as demonstrated in Fig. 1. Protein-bound phosphate was measured by a combination of the general assay for phosphoester bonds in proteins[22] with the assay of inorganic phosphate of Itaya and Ui[23] and the ashing procedure of Ames[24], as detailed by Stull and Buss[4]. Protein was quantified by the method of Bradford[25] using bovine serum as a standard. We used a value of 23,550, as determined by amino acid analysis[26], as the molecular weight of TNI for our calculations.

high-calcium media. Nonetheless, the hypothesis that cardiac troponin may be phosphorylated *in vivo* in response to stimuli which increase cyclic AMP[5] and that this phosphorylation may be associated with increased contractile force[3] remains attractive. Our data suggest that this hypothesis must be modified since PGE_1 increases cyclic AMP but causes no net phosphorylation of TNI.

We have previously[2] discussed several possible explanations for this anomalous effect of PGE_1. A direct inhibitory effect of PGE_1 at a stage distal to protein kinase activation is unlikely since a high concentration of PGE_1 (30 μM) caused no inhibition of phosphorylase *a* formation, TNI phosphorylation, or the inotropic effects of 10 nM isoprenaline. We have not been able to detect an increase in phosphoprotein phosphatase activity due to PGE_1 (ref. 2). Maximally effective concentrations of the two agents produced the same activation of protein kinase as did isoprenaline alone, suggesting that we are not dealing with two populations of responsive cells. We must also consider the possibility that PGE_1 caused a transient change in protein phosphorylation such that our measurements, made on hearts freeze-clamped after 2 min of drug treatment, would not reflect the transient effect. Constant monitoring showed no transient change in dP/dt during the 2 min of treatment. The data of Keely (ref. 11 and personal communication) demonstrate that continuous perfusion with catecholamine or PGE_1 causes quick increases in cyclic AMP content and protein kinase activity ratios that are maintained for the duration of drug treatment (up to 10 min). During a 10-min treatment, catecholamine causes a sustained activation of phosphorylase whereas PGE_1 elicits no activation[11]. Thus, it seems that PGE_1 causes no transient increase in protein phosphorylation. England has demonstrated the persistence of TNI-bound phosphate following a pulse of isoprenaline[3]. His result suggests that a transient activation of TNI phosphorylation might still be noticeable as increased TNI-bound phosphate at a later time. Consideration of these points argues against a transient change in protein phosphorylation in response to PGE_1.

Two alternative explanations are attractive: that β-adrenergic stimulation supplies a 'factor' that PGE_1 does not, or that PGE_1 and isoprenaline activate protein kinases in different cellular compartments. We have previously discussed these possibilities with respect to the regulation of cardiac glycogen metabolism. If β-agonists supply a specific factor necessary for the expression of protein kinase activity, it would probably not be Ca^{2+}, since protein kinase is not known to require this cation[2]. In the present case, however, the discussion must be more tentative since the regulation of TNI phosphorylation and contractility by cyclic AMP-dependent protein kinase is by no means as clearly established as the involvement of protein kinase in the stimulation of glycogenolysis and because Ca^{2+} is intimately involved in the contractile process. The compartition of protein kinase within the cell and the activation of an ineffective pool of the kinase in response to PGE_1 are testable hypotheses. Several 'pools' of protein kinase are known—particulate and soluble, isozymes I and II (refs 12, 13); substrates and cyclic AMP, too, can be localised[14,15].

To test the possibility that the two isozymes of protein kinase might be selectively involved in the differing responses to isoprenaline and PGE_1, we have looked for hormonal specificity in hearts differing in their content of the isozymes—rat (>80% type I) and guinea pig (>90% type II)[12,16]. In both of these preparations, isoprenaline and PGE_1 increase intracellular cyclic AMP and cause comparable elevations of the protein kinase activity ratio, but only isoprenaline causes the activation of glycogen phosphorylase and an enhanced dP/dt. Thus, activation of protein kinase and the hormonally specific expression of protein kinase activity occur in hearts in which either isozyme of protein kinase predominates (data not shown).

The present results confirm that TNI-bound phosphate increases in perfused rat heart treated with isoprenaline. The phosphorylation of TNI is functionally relevant to the extent that enhanced dP/dt and increased TNI-phosphate occur concurrently; and when, following exposure to PGE_1, we record no change in dP/dt, we find no change in the phosphate content of TNI.

Our study indicates that TNI phosphorylation and other sequelae are not the consequence merely of increased intracellular cyclic AMP. β-Adrenergic stimulation must provide a signal more complex than a generalised stimulation of cyclic AMP formation, since neither enhanced dP/dt nor increased phosphate content of TNI nor phosphorylase activation results from treatment of perfused rat heart with PGE_1, even though

PGE_1 increases both cardiac cyclic AMP content and the activity ratio of soluble protein kinase (Table 1). England's results[3] suggest that glucagon may also provide the appropriate stimuli for enhanced protein phosphorylation and positive inotropism. This hormonally specific expression of protein kinase activity seems unrelated to the predominance of either of the isozymes of protein kinase. We are now extending these observations and considering the biochemical data in light of known functional and morphological compartments of the heart and in light of previous reports on functional pools of cyclic AMP and cyclic AMP-dependent protein kinases[12-15]. We are also aware that the compartition of cyclic AMP and protein kinases could have intriguing implications for the relationship of hormonal receptors, adenylate cyclase, and intracellular compartments.

We thank Michael Branks for technical assistance, Professor James T. Stull for loan of TNC affinity columns, Professor James W. Covell for his interest and Sandra Dutky for help in preparing the manuscript. Fellowships from the NIH (HL05363, to LLB) and the California Heart Association (to JSH) supported this work.

High-frequency generalised transduction by bacteriophage T4

GENERALISED transduction—the transfer of bacterial genes from one cell to another via bacteriophages—is one of a small number of processes by which bacteria can acquire exogenous genetic information. Transduction was first demonstrated in *Salmonella typhimurium* with the phage P22 by Zinder and Lederberg[1,2] and subsequently in *Escherichia coli* with the phages P1[3] and T1[4]. Bacteriophage T4 is the largest, and one of the most thoroughly studied of the virulent coliphages but has never been observed to mediate generalised transduction. In this report we describe a multiple mutant of T4 that displays the property of generalised transduction, and transfers *E. coli* genes with frequencies that, in general, are higher than those observed for other transducing phages.

The DNA of wild-type T4 contains glucosylated hydroxymethylcytosine (glu-HMC) in place of cytosine which enables the phage to escape host-controlled DNA restriction. Multiply mutated derivatives of T4 have been isolated which are defective in several genes involved in the synthesis of HMC and the degradation of cytosine-containing DNA[5]. We examined one such mutant, constructed originally for molecular cloning purposes, to see if it had the ability to transduce bacterial DNA. Mutant T4GT7 (T4 generalised transducer no. 7) was isolated as a pseudorevertant of the triple mutant *am*E51 (g*56*, dCTPase), *am*C87 (g*42*; dHMase), NB5060 (deletion spanning rIIB, *denB*, *ac*) on a restriction deficient, non-amber suppressing (Sup°) *E. coli* K host. The revertant carries an additional spontaneous *alc*$^-$ mutation (E. Kutter, personal communication) and yields progeny with cytosine-containing DNA. The progeny DNA is sensitive to *in vivo* restriction by the plasmid-specified *Eco*RI system, and *in vitro* the DNA is cleaved by many restriction endonucleases[6]. When the mutant is grown on an amber-suppressing host (Sup$^+$) permitting g*56* and g*42* to function, it produces progeny containing glu-HMC DNA which is resistant to restriction both *in vivo* and *in vitro*.

When auxotrophic strains of *E. coli* are infected with T4GT7 previously grown on bacteria carrying wild-type alleles, transductants arise at high frequency for most markers tested. Among the host markers for which we have observed transduction are the amino acids *leu* (2 min), *proA* (6 min), *his* (44 min), *arg G* (68 min) and *metB* (87 min), and the sugars *ara* (2 min), *lac* (8 min) and *xyl* (79 min) (ref. 7). In general, transductants arise at frequencies around 1 per 10^4 singly infected cells, but marker-dependent variation is observed (Table 1). For some markers, notably *thr* (0 min), *malA* (74 min) and *mtl* (80 min) no transductants at all have been observed. Wild-type T4 is unable to transduce any of the markers we have tested; P1 does so, but at a much lower frequency than T4GT7, around 1×10^{-6}. To date we have only observed co-transduction for the closely linked markers *ara* and *leu* which are co-transduced at the single marker frequency. The transducing capacity of T4GT7 lysates is not diminished by treatment with either DNase or RNase, eliminating the possibility that we are observing transformation rather than transduction. Finally, the number of transductants increases with increasing multiplicity of infection (MOI) through the range 0.001 to 0.5, then falls off sharply at higher MOIs as multiple infections reduce the number of singly infected, potentially transduceable cells (Fig. 1). Together these data firmly establish that the mutant T4 phage are capable of generalised transduction.

In addition to transducing chromosomal markers, T4GT7 transduces extrachromosomal, plasmid-borne markers. Lysates

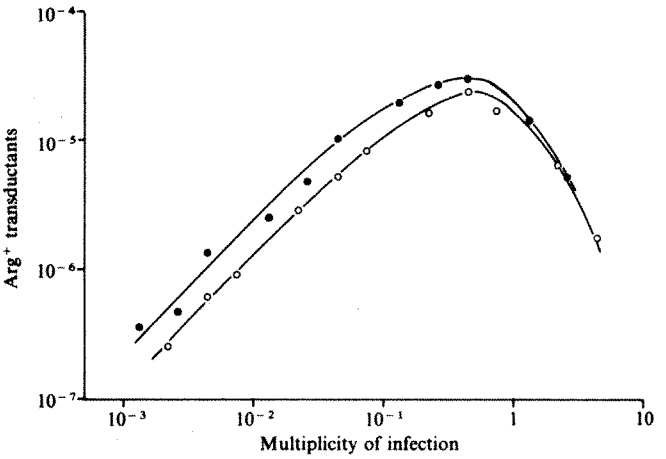

Fig. 1 Influence of multiplicity of infection on the formation of transductants. A culture of log-phase bacteria (JC411) was infected with T4GT7 at increasing multiplicities of infection and plated on minimal plates containing all the necessary supplements except arginine. The numbers of Arg$^+$ transductants were counted and are plotted here as the ratio of transductants to total cells plated. Data from two different experiments using independently prepared phage lysates are shown.

Table 1 The frequencies with which T4GT7, T4 wild type and phage P1 transduce auxotrophic recipient strains JC 411 and AB 1157

	JC 411			AB 1157			
MetB	*ArgG*	*His*	*Leu*	*Leu*	*Ara*	*ProA*	*Thr*
T4GT7 3.6×10^{-4}	7.1×10^{-5}	7.8×10^{-5}	1.1×10^{-4}	8.3×10^{-5}	5.9×10^{-5}	3.5×10^{-6}	$<10^{-7}$
P1 cm 1×10^{-6}	3×10^{-6}	3×10^{-6}	1×10^{-5}	7×10^{-6}	3×10^{-6}	10^{-7}	$<10^{-7}$
T4 wild type $<10^{-8}$	$<10^{-8}$	$<10^{-8}$	$<10^{-8}$	$<10^{-8}$	$<10^{-8}$	$<10^{-8}$	$<10^{-8}$

The phage were grown on *E. coli* K ED8689 (hsdR$^-$, Sup^0) either as liquid or plate lysates. Recipient cells were grown to log phase in supplemented M9 minimal medium, resuspended in fresh medium in the presence of 20 μg ml^{-1} L-tryptophan to a titre of approximately 4×10^8 cells per ml and infected with sufficient phage to achieve a multiplicity of infection in the range 0.05–0.25. After 15 min adsorption at room temperature, aliquots of the infection mixtures were spread onto minimal selection plates and incubated for 2 days at 37 °C to allow growth of transductant colonies. Immediately before infection, the recipient cells were titred to determine the actual MOI. The data are shown as ratios of the number of transductants observed to the number of singly infected cells plated, the latter calculated from the Poisson formula knowing the cell titre and MOI. The absolute frequency with which markers are transduced varies two- to threefold from lysate to lysate. This fluctuation seems to be due to differences in the intracellular growth times of different phage preparations (Fig. 2). Lysates prepared on Sup$^+$ donor bacteria have two- to threefold lower transducing capacities than lysates prepared on Sup^0 hosts.

of the phage prepared on donors containing the antibiotic resistance-determining plasmids pBR322 or RP4 were found to transduce the recipient strain JC411 to ampicillin resistance. To standardise for donor-dependent differences in transducing capacity in these experiments, transduction for the chromosomal *arg* marker was simultaneously measured. Routinely, ampicillin resistance was found to be transduced twice as frequently as Arg$^+$ from the pBR322-containing host, but only 1/20th as frequently from the RP4-containing host. As plasmid pBR322 exists in approximately 50 copies per cell[8] whereas plasmid RP4 exists in only a few copies[9], a diference in relative transduction frequency would be expected and is observed. The majority (170/171) of ampicillin-resistant transductants tested from the pBR322-grown lysate also were found to be tetracycline resistant, suggesting that the entire plasmid may be transduced although this has not been proved conclusively.

To determine at which stage during the development of T4GT7 transducing particles form, samples of a phage-infected bacterial culture were artificially lysed at various times after infection. The Arg$^+$ transducing capacity reached a maximum 30 min after infection and declined thereafter (Fig. 2). The maximum for Arg$^+$ transductants is about 10 times higher than the frequency observed in lysates that have been incubated for several hours. Most, but not all, other markers also showed an early maximum. The transducing capacity curve presumably reflects variation in the rates at which chromosomal fragments

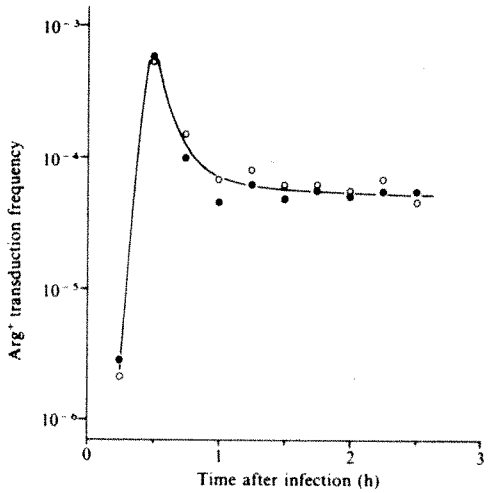

Fig. 2 Kinetics of transducing particle formation. A log-phase culture of ED8689 was infected at time zero with T4GT7 at a MOI of 5. Ten minutes later the culture was superinfected with the same multiplicity of phage to induce lysis inhibition. Starting at 15 min, and at 15-min intervals thereafter, samples of the infected cells were taken, lysed with chloroform, and the plaque-forming progeny titred. The infected cells were incubated at 37 °C with aeration throughout the experiment. Once the titre had been established, the Arg$^+$ transducing capacity of each sample was determined with JC 411 at MOI 0.5. Two independent estimates were made and both sets of data are shown.

and phage DNA molecules are packaged and accumulate and accounts for variation in transduction from lysate to lysate. Although the maximum transduction frequency is observed for the 30-min lysate, the formation of transducing particles does not cease at that time. Multiplying the transduction frequency by the viable phage titre at each time point during the lytic cycle indicates that transducing particles accumulate for at least an hour after infection and thereafter their number remains unchanged.

Possession of a circularly permuted phage chromosome and the ability to carry out generalised transduction often go hand in hand. Bacteriophage T4 is the classical circularly permuted phage[10], and although the wild-type phage is unable to transduce, the multiply mutated derivative T4GT7, described here, can. We are not yet certain whether all the mutations present in the mutant are critical for transduction. Since suppression of the *amber* mutations in genes *42* and *56* reduces the transducing capacity only slightly, it is probable that these two mutations are irrelevant. The remaining mutations, *denB*$^-$ and *alc*$^-$, are almost certainly required for transduction since both affect host and phage DNA after infection. The *denB*$^-$ mutation is a large deletion; in addition to abolishing the T4 cytosine-DNA-specific endonuclease IV, it also eliminates the *rIIB* and *ndd* functions[11], *ndd* being involved in the disruption of the host nucleoid[12]. The *alc*$^-$ mutation affects transcription from cytosine containing templates[5] and could also affect the *unf* function[13], responsible for unfolding the bacterial chromosome, as other *alc*$^-$ mutations are known to do[14]. Since T4GT7 was isolated as a plaque-forming derivative of the triple mutant, the possibility exists that it carries additional mutations beside *alc*$^-$. Further analysis is under way to determine the precise genetics of T4 transduction.

At present, we do not know the form in which host DNA is transduced by T4GT7. Like P1[15] and P22[16], T4GT7 might transduce continuous sections of the host chromosome in linear, headful-sized pieces. Alternatively it might scramble the chromosome and package otherwise unlinked fragments in the same head; or, like phage Mu[17], it may couple fragments of host and viral DNA and encapsulate hybrid molecules.

The observations presented here indicate that T4 is capable of efficient generalised transduction. Both the phage and its host are well understood from the genetic and physiological points of view[7,18]. T4 is twice the size of P1 and might be expected to co-transduce correspondingly larger sections of the host chromosome, perhaps up to 5-min as compared with 2-min for P1. The increased capacity, together with its higher transducing frequency, recommend T4GT7 as an alternative to P1 for practical laboratory use and other applications.

Inability of circular mRNA to attach to eukaryotic ribosomes

IN contrast to prokaryotic systems, initiation by eukaryotic ribosomes seems to be restricted to a single site near the 5′-terminus of the message. However, nucleotide sequence analyses have not revealed a common 'recognition sequence' within the 5′-proximal portion of eukaryotic messages. We have previously suggested that the position of an AUG codon within a eukaryotic message—rather than the surrounding nucleotide sequence—might be the primary feature defining an initiation site. We proposed[1,2] that a 40S ribosomal subunit binds initially at or near the 5′-end of a message and migrates along the RNA chain until the first AUG codon is encountered, whereupon it stops, a 60S subunit joins, and polypeptide synthesis begins. Although this mechanism accounts for many of the peculiarities of eukaryotic translational initiation, it leaves unanswered the question of how ribosomes recognise the 5′-terminus of mRNA. The m^7G cap which blocks the end of most eukaryotic messages[3] is not responsible for directing ribosomes to the 5′-terminus since ribosomes initiate at the 5′-proximal AUG even in uncapped or unmethylated RNAs[4,5]. The ability of ribosomes to select the 5′-end of a message irrespective of its chemical structure (that is, whether the terminus is $m^7GpppN\ldots$, $GpppN\ldots$ or $pppN\ldots$) is difficult to explain. An intriguing possibility is that eukaryotic ribosomes attach to mRNA by a threading mechanism. A simple prediction of the threading mechanism is that circularisation of a message should abolish its ability to interact with ribosomes. The experiments described below fulfill this prediction. The possibility of threading by prokaryotic ribosomes was ruled out, several years ago, by the demonstration that *Escherichia coli* ribosomes were able to translate the circular DNA of phage fd[6,7]. Indeed, the simplest version of a threading mechanism (entry at the 5′-terminus of a message with translation beginning at the first AUG codon encountered by the ribosome) is contradicted by the ability of *E. coli* ribosomes to initiate at multiple internal sites in polycistronic messages, such as bacteriophage R17 RNA. Conversely, the threading mechanism is consistent with the monocistronic character of eukaryotic messages.

These experiments were designed to determine whether mRNA molecules retain the capacity to attach to eukaryotic ribosomes after circularisation of the message, catalysed by T4 RNA ligase[8]. Templates were sought which were able to bind with reasonable efficiency to both prokaryotic and eukaryotic ribosomes, and were small enough to undergo circularisation. Two kinds of synthetic polymers met these requirements. One series of experiments was carried out with linear and circular molecules containing a single AUG codon flanked by polyadenylic acid. A random copolymer of adenylic, uridylic and guanylic acid was used for another set of experiments.

Circular ^{32}P-labelled molecules containing a single AUG codon were synthesised as follows. (1) The dinucleotide UpG was converted to $UpG(pA)_n$ in a reaction catalysed by primer-dependent polynucleotide phosphorylase[9] (PNPase), with ^3H-ADP as precursor. In the presence of 0.5 M NaCl, a homo-

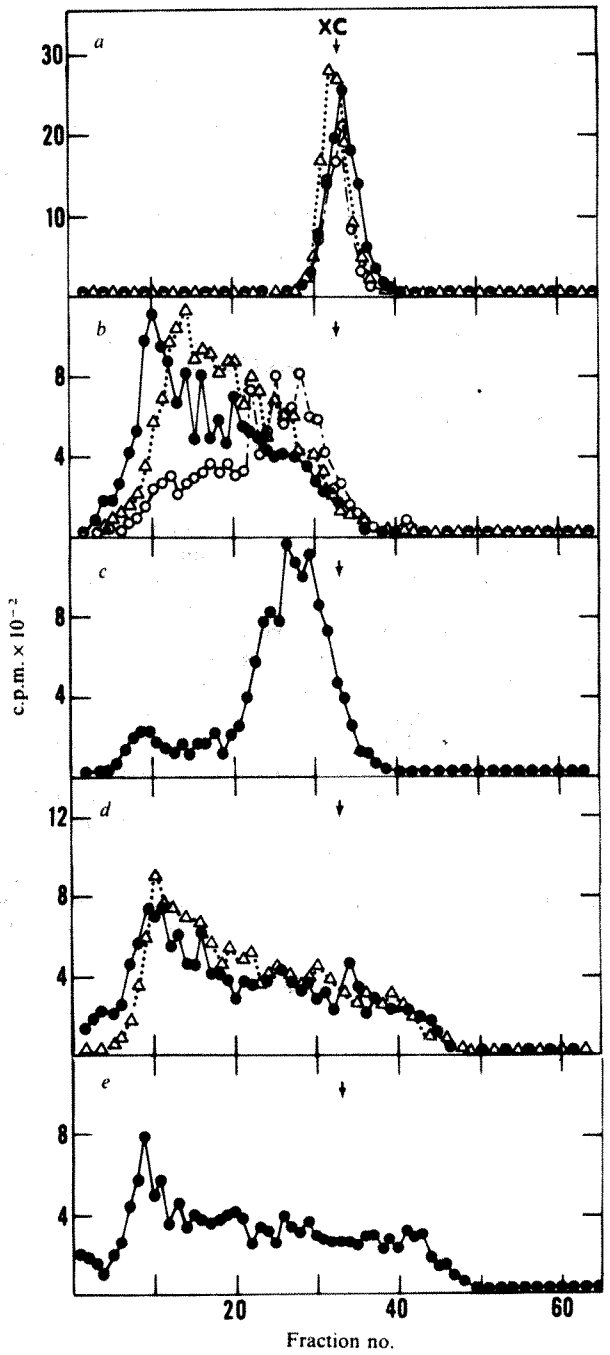

Fig. 1 Polyacrylamide gel electrophoresis of ^{32}P-labelled ribopolymers. The origin is at the left. Three forms of the polymer $UpG(pA)_{25}$ were analysed in separate gels, and the three profiles are superimposed in *a*: linear [5′-^{32}P]pUpG$(pA)_{25}$ before circularisation (△ . . . △); after reaction with RNA ligase (●——●); and after cleavage of the circular molecules with T_1 RNase (○-·-○). Incubation with T_1 RNase (40 U enzyme and 20 μg of RNA per 60 μl reaction) was for 20 min at 37 °C, followed by phenol–SDS extraction and ethanol precipitation. The same symbols in *b* represent three forms of the polymer $UpG(pA)_{110}$. After reaction with RNA ligase, an aliquot of $UpG(pA)_{110}$ was further treated with PNPase to degrade residual linear molecules (*c*). Electrophoresis of [5′-^{32}P]poly(A, U, G) linear (△ . . . △) and circular (●——●) molecules is shown in *d*. An aliquot of purified poly(A, U, G) circles, from which linear molecules had been removed with PNPase, was analysed in *e*. Composition of the gels and electrophoresis conditions were as described previously[10]. Arrows show the position of xylene cyanol FF blue (XC). Other markers were bromophenol blue (fraction 61) and transfer RNA (fraction 21).

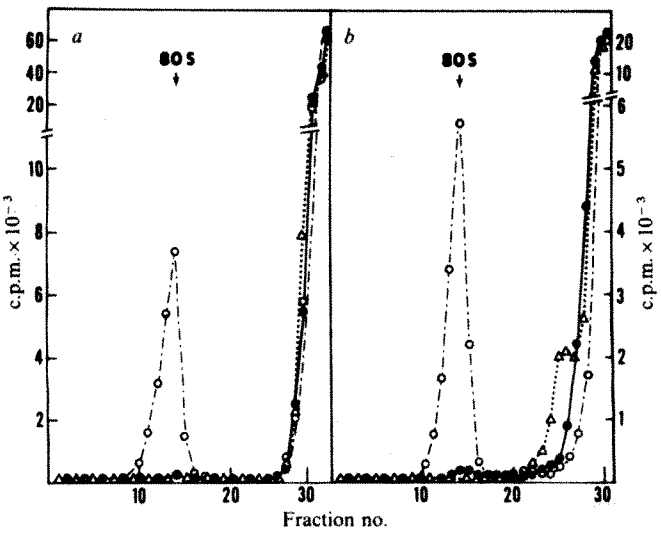

Fig. 2 Binding of ^{32}P-labelled pUpG(pA)$_n$ polymers to wheat-germ ribosomes. *a*, Binding of three forms of the polymer pUpG(pA)$_{25}$ (150,000 c.p.m. per 50 μl reaction); *b*, binding of three forms of the polymer pUpG(pA)$_{110}$ (80,000 c.p.m. per 50 μl reaction). Polymers were tested for ribosome binding before reaction with RNA ligase (△ . . . △), after circularisation with RNA ligase (●——●), and after cleavage of the circles with T_1 RNase (○ - · - ○). Reaction conditions with wheat-germ S23 extract were as described previously[2,10]. Following 6 min incubation at 19 °C, samples were chilled and layered on to 10–30% glycerol gradients. Centrifugation was for 3 h in a SW41 rotor. The direction of sedimentation was from right to left in all gradients. Gradient fractions (0.37 ml) were mixed with Beckman GP scintillation cocktail and counted for radioactivity. In each panel, profiles obtained from three parallel gradients have been superimposed.

geneous polymer containing ~25 adenylic acid residues was obtained (Fig. 1*a*, triangles). Higher molecular weight polymers (which were also more heterogeneous in size, Fig. 1*b*, triangles) were obtained by lowering the NaCl concentration[11]. (See Table 1 for reaction conditions.) Average chain lengths of 25 and 110 nucleotides for UpG(pA)$_n$ preparations 1 and 2, respectively, were determined from the ratio of ^{3}H-labelled adenosine/3′-AMP, following alkaline hydrolysis (not shown). (2) The linear molecules of UpG(pA)$_n$ were labelled at the 5′-terminus by phosphate transfer from [γ-^{32}P]ATP, catalysed by polynucleotide kinase. (3) Subsequent incubation with RNA ligase converted a substantial fraction of the 5′-terminal label to a form resistant to alkaline phosphatase (Table 1, 1*b* and 2*b*). As expected, the efficiency of ligation was greater with the shorter polymers (preparation 1) than with the longer molecules in preparation 2. Incorporation of 5′-^{32}P into an internal phosphodiester bond, suggested by resistance to alkaline phosphatase, was confirmed by analysing the products of alkaline hydrolysis. Whereas the linear polymer [5′-^{32}P]pUpG(pA)$_n$ yielded pUp as the only ^{32}P-labelled product (Table 1), after incubation with RNA ligase ^{32}P-radioactivity from preparation 1 was quantitatively recovered as 3′-AMP (Table 1). Thus, preparation 1*b* seemed to consist entirely of circular molecules. Preparation 2*b*, on the other hand, clearly contained residual linear monomers (and perhaps linear dimers) as only 43% of the ^{32}P-radioactivity was recovered as 3′-AMP after alkaline hydrolysis. The residual linear molecules were eliminated by treatment with PNPase, yielding the purified circle preparation 2*c* in Table 1. (Comparison of the polyacrylamide gel profiles of preparations 2*a* (Fig. 1*b*, triangles) and 2*c* (Fig. 1*c*) reveals that the smaller molecules in the linear preparation were preferentially circularised. Although the average chain length of the linear molecules was 110 nucleotides, the majority of the circular molecules were in the range 40–80 nucleotides. Thus, preparations 2*b* and *c* are represented as pUpG(pA)$_{40-80}$ in the following paragraphs.) (4) Finally, an aliquot of each pUpG(pA)$_n$ circle preparation was treated with ribonuclease T_1, which cleaves on the 3′-side of guanosine residues, thereby converting each circle into a linear molecule terminating in AUG. This provided a useful control for the ribosome binding experiments described below and the treatment with T_1 RNase also confirmed that putative pUpG(pA)$_n$ circles had not been randomly cleaved by contaminating nuclease(s) at any stage (as the size of the linear (Ap)$_{25}$UpGp molecules obtained after T_1

Table 1 Characterisation of linear and circular ribopolymers

^{32}P-labelled polymer preparation	Resistance to alkaline phosphatase	Resistance to polynucleotide phosphorylase	Products of alkaline hydrolysis	
			pUp	3′-AMP
1*a* Linear [5′-^{32}P]pUpG(pA)$_{25}$	0.2%	not done	100%	0%
1*b* [5′-^{32}P]pUpG(pA)$_{25}$ after reaction with RNA ligase	88%	90%	1%	99%
2*a* Linear [5′-^{32}P]pUpG(pA)$_{110}$	0.3%	5%	100%	0%
2*b* [5′-^{32}P]pUpG(pA)$_{110}$ after reaction with RNA ligase	29%	25%	57%	43%
2*c* Circular ^{32}P-labelled pUpG(pA)$_{110}$ after hydrolysis of residual linear molecules with PNPase	80%	(100%)	11%	89%
3*a* Linear [5′-^{32}P]poly(A, U, G)	0.4%	10%	not done	
3*b* [5′-^{32}P]-poly(A, U, G) after reaction with RNA ligase	76%	73%	not done	

Polymer preparation 1*a* was synthesised in a 200-μl reaction mixture containing 0.2 M Tris·Cl (*p*H 8.3), 0.5 M NaCl, 10 mM magnesium acetate, 0.7 mM UpG, 25 mM ^{3}H-ADP (1.8 mCi mmol^{-1}, NEN) and 1.25 U primer-dependent PNPase (PL Biochemicals). After incubation for 6 h at 34 °C the product was extracted with phenol, and unincorporated precursors were removed by filtration through Sephadex G-25. Similar conditions were used for preparation 2*a*, except that the concentration of UpG primer was 0.2 mM, and 0.2 M NaCl was used. Linear polymers (1*a*, 2*a*, 3*a*) were labelled at the 5′-terminus in reaction mixtures (125 μl) containing 36 mM Tris·Cl (*p*H 8), 120 mM NaCl, 10 mM $MgCl_2$, 10 mM dithiothreitol (DTT), 3.5 μg bovine serum albumin (BSA), 50 μg of polymer, 40 μC of [γ-^{32}P]ATP (33 Ci mmol^{-1}, NEN) and 3 U polynucleotide kinase (PL Biochemicals). Following incubation for 60 min at 37 °C the labelled polymers were extracted with phenol and filtrated through Sephadex G-25. Circular polymers (1*b*, 2*b*, 3*b*) were obtained by reaction with T4 RNA ligase, using the low temperature conditions suggested by Bruce and Uhlenbeck[12]. Reaction mixtures (450 μl) contained 1.6×10^7 c.p.m. of 5′-end labelled polymer, 11 U of RNA ligase (PL Biochemicals), 14 μg BSA, 10% (v/v) dimethyl sulphoxide, 50 mM HEPES (*p*H 7.6), 10 mM $MgCl_2$, 4 mM DTT and 0.2 mM ATP. Incubation was for 19–24 h at 4 °C. Hydrolysis of linear molecules with PNPase (preparation 2*c* and column 3) was accomplished by incubation for 40 min at 35 °C with 15 U ml^{-1} of primer-independent PNPase (type 15, PL Biochemicals) in 50 mM Tris·Cl (*p*H 8.8), 175 mM NaCl, 10 mM K_2HPO_4, 10 mM $MgCl_2$, 1 mM EDTA and 17 μg BSA per ml. Carrier RNA was present at 100 μg ml^{-1}. For preparation 2*c*, the reaction was terminated by extraction with phenol-SDS, and low molecular weight products were removed by filtration through Sephadex G25. For the analytical PNPase analyses in column 3, radioactive polymers were precipitated with 5% trichloroacetic acid (TCA) at 4 °C and then counted on Millipore filters. Resistance to alkaline phosphatase (column 2) is based on TCA-precipitable radioactivity following incubation at 37 °C for 40 min with bacterial alkaline phosphatase (2 U ml^{-1}, Worthington), in 20 mM Tris·Cl (*p*H 8). The products of alkaline hydrolysis were identified by high voltage paper electrophoresis following incubation in 0.5 M KOH at 37 °C for 18 h.

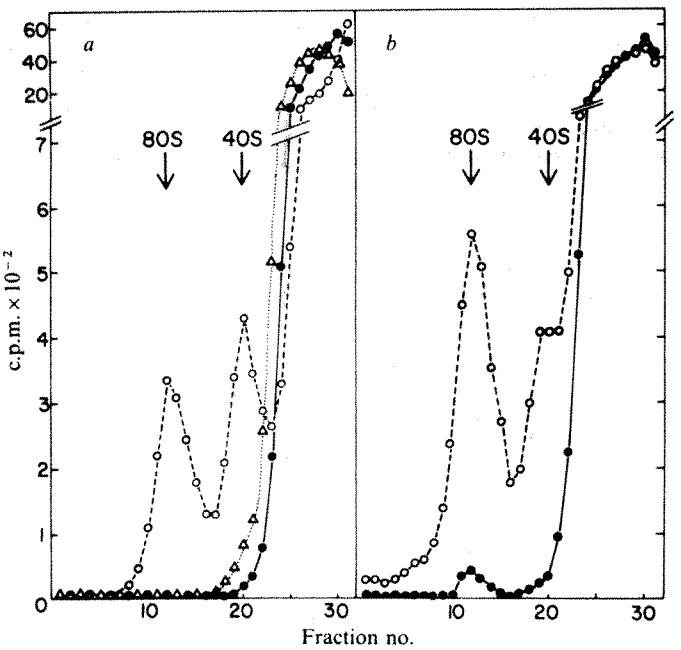

Fig. 3 Binding of linear and circular ^{32}P-labelled polymers to reticulocyte ribosomes. *a*, Three forms of the polymer pUpG(pA)$_{110}$ were incubated with rabbit reticulocyte ribosomes: △...△, linear molecules before ligation; ●——●, circles; ○---○, circles which had been cleaved with T_1 RNase. Reaction conditions were as described previously[13]. Incubation was for 8 min at 32 °C. Profiles from three parallel gradients have been superimposed. In *b*, linear (○---○) and circular (●——●) forms of poly (A, U, G) were tested. Each 200-μl reaction mixture contained 30,000 c.p.m.

RNase digestion of the circle preparation in Fig. 1*a* (open circles) was identical to that of the starting pUpG(pA)$_{25}$ linear molecules (triangles)). With the second preparation, the average size of the T_1 RNase-treated material (Fig. 1*b*, open circles) was smaller than the original linear pUpG(pA)$_{110}$ molecules (Fig. 1*b*, triangles), consistent with the interpretation that only the smaller chains had been circularised. The third polymer preparation used in these studies was a random copolymer of adenylic, uridylic and guanylic acid. Poly(A, U, G) (Miles) was treated with alkaline phosphatase to generate a 3′-hydroxyl terminus and was subsequently labelled at the 5′-end with [γ-^{32}P]ATP (Table 1, 3*a*). An aliquot of [5′-^{32}P]poly(A, U, G) was incubated with RNA ligase, resulting in ~75% circularisation (Table 1, 3*b*). For some of the ribosome binding studies described below, residual linear molecules in the poly(A, U, G) circle preparation were hydrolysed with PNPase. The resulting purified poly(A, U, G) circle preparation was 90% resistant to alkaline phosphatase. Figure 1*d* and *e* show that, although there was considerable heterogeneity in the size of the poly(A, U, G) circles, most of the molecules were larger than 80 nucleotides.

Linear and circular forms of polymers containing a single AUG codon, flanked by poly(A), were tested for ability to interact with wheat-germ (Fig. 2), reticulocyte (Fig. 3*a*) and *E. coli* ribosomes (Fig. 4*a*). One reason for the selection of [5′-^{32}P]pUpG(pA)$_{25}$ as substrate for the RNA ligase reaction is that, before circularisation, the polymer does not contain an AUG codon. Thus, the linear precursor showed no detectable stable binding to wheat-germ ribosomes (Fig. 2*a*, triangles). Although circularisation of pUpG(pA)$_{25}$ creates an AUG initiator codon, circular pUpG(pA)$_{25}$ was also unable to bind to wheat-germ ribosomes (Fig. 2*a*, closed circles). When the circles were hydrolysed with RNase T_1, however, the resulting linear molecules were able to form stable 80S complexes (Fig. 2*a*, open circles). Thus, inability of wheat-germ ribosomes to bind to circular pUpG(pA)$_{25}$ cannot be attributed to absence of a proper initiation sequence. The sequence (Ap)$_n$UpGp (in a linear molecule) is adequate for stable attachment of wheat-germ ribosomes, although the level of binding (~15%) was lower than would be observed with most natural messages. Failure of pUpG(pA)$_{25}$ circles to interact with wheat-germ ribosomes might, however, be due to the small size of the circles. Indeed, the preparation of circles tested with wheat-germ ribosomes in Fig. 2*a* also failed to bind stably to *E. coli* ribosomes (not shown). Thus, the experiment in Fig. 2*a* was repeated using bigger polymers. The gradient profile in Fig. 2*b* (closed circles) shows only a very low level of binding (<1%) when circular molecules of the form pUpG(pA)$_{40-80}$ were incubated with wheat-germ ribosomes. In contrast, 16% of the linear molecules resulting from T_1 RNase digestion (Fig. 2*b*, open circles) bound to wheat-germ 80S ribosomes. Figure 3*a* shows that reticulocyte ribosomes, like the wheat-germ system, discriminated against circular forms of the polymer pUpG(pA)$_{40-80}$.

In control experiments, linear and circular molecules of pUpG(pA)$_{40-80}$ were tested for the ability to bind to *E. coli* ribosomes. Even without an AUG codon linear [5′-^{32}P]pUpG(pA)$_{110}$ showed a fairly high level of binding to *E. coli* ribosomes, varying from 3 to 10% of the input polymer. Therefore, to show that circular molecules can attach to *E. coli* ribosomes, binding had to be carried out using a purified preparation of pUpG(pA)$_{40-80}$ circles (Table 1, line 2*c*) which was free of residual linear molecules. Figure 4*a* (closed circles) shows that 12% of the purified circles formed 70S initiation complexes with *E. coli* ribosomes which were fixed with glutaraldehyde[14] before centrifugation. Binding to *E. coli* ribosomes was also detectable although at a reduced level without glutaraldehyde fixation (Fig. 4*a*, open circles). In contrast, the

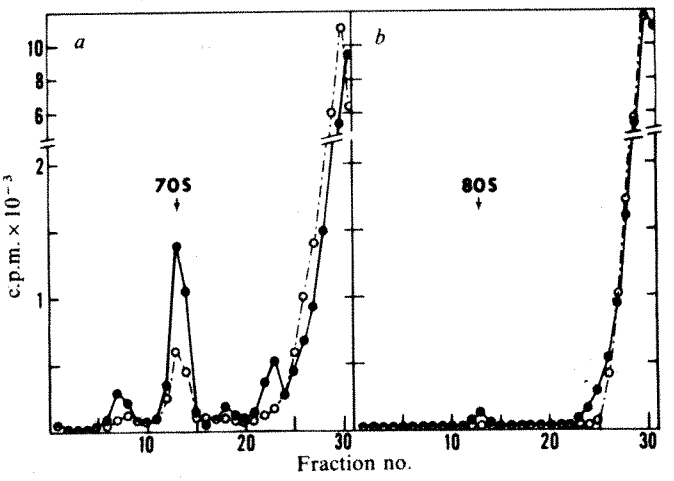

Fig. 4 Binding of purified ^{32}P-labelled pUpG(pA)$_{40-80}$ circles to: *a*, *E. coli*; and *b*, wheat-germ ribosomes. Each 50-μl reaction mixture contained 60,000 c.p.m. of the polymer described in 2*c* of Table 1. For binding to *E. coli* ribosomes (*a*), the 50-μl reaction mixture contained 50 mM HEPES(NH$_4$), *p*H 7.5, 100 mM NH$_4$Cl, 6.6 mM magnesium acetate, 0.1 mM EDTA, 0.6 mM DTT, 0.5 mM GTP, 55 μg of *E. coli* MRE600 tRNA charged with methionine in formylating conditions, and 2.3 A_{260} units of low salt washed *E. coli* Q13 ribosomes. The ribosomes (retaining initiation factors, but free of elongation factors) were obtained by pelleting from an S30 extract and washing twice with 20 mM HEPES (*p*H 7.5), 60 mM NH$_4$Cl, 10 mM magnesium acetate and 6 mM β-mercaptoethanol. Incubation of the ^{32}P-labelled polymer with *E. coli* ribosomes was for 8 min at 35 °C followed by sedimentation through a 10–30% sucrose gradient containing 20 mM HEPES (*p*H 7.6), 50 mM NH$_4$Cl, 7 mM magnesium acetate, 0.1 mM EDTA and 6 mM β-mercaptoethanol. Centrifugation was for 3.25 h at 4 °C in the SW41 rotor. Reaction conditions used with wheat-germ ribosomes (*b*) were as described in Fig. 2. After incubation with either wheat-germ or *E. coli* ribosomes, half of each sample was directly applied to a gradient (○-·-○); the remainder was fixed by addition of 7 μg BSA and 2 vol 2.5% glutaraldehyde in 50 mM HEPES (*p*H 7.5), 50 mM KCl and 5 mM magnesium acetate. After 5 min at 4 °C the glutaraldehyde-treated samples (●——●) were layered on to gradients and centrifuged.

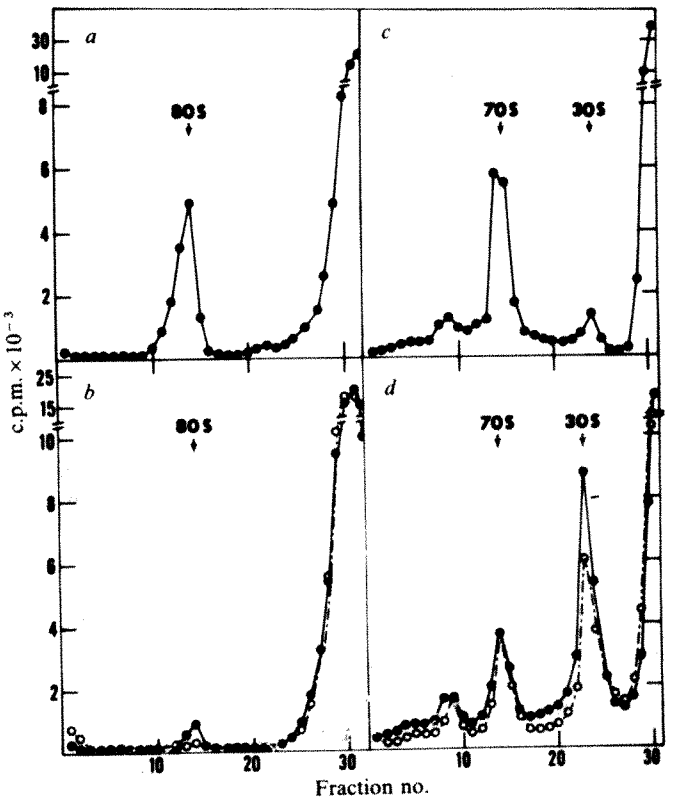

Fig. 5 Binding of ^{32}P-labelled linear and circular poly(A, U, G) to wheat-germ and *E. coli* ribosomes. Reaction conditions were as described in Figs 2 and 4, and initiation complex formation was assayed by centrifugation through gradients. Binding of linear [5′-^{32}P]poly(A, U, G) is shown with wheat-germ ribosomes (*a*) and with *E. coli* ribosomes (*c*). Circular poly(A, U, G) was incubated with wheat-germ ribosomes in *b* and with *E. coli* ribosomes in *d*. In *b* and *d*, binding is shown for the poly(A, U, G) circle preparation described in line 3*b* of Table 1 (●——●) and also for a more highly purified preparation (○- - -○) from which residual linear molecules had been removed by hydrolysis with PNPase. Each reaction mixture contained 75,000 c.p.m. Samples were not fixed with glutaraldehyde.

same preparation of purified pUpG(pA)$_{40-80}$ circles showed no stable interaction with wheat-germ ribosomes, with or without glutaraldehyde fixation (Fig. 4*b*).

Another series of ribosome binding experiments was carried out with linear and circular forms of poly(A, U, G). Linear [5′-^{32}P]poly(A, U, G) bound with approximately the same efficiency to wheat-germ (Fig. 5*a*) as to *E. coli* ribosomes (Fig. 5*c*). Circularisation of the template strikingly reduced its capacity to bind to wheat-germ ribosomes (Fig. 5*b*, closed circles). The very low (3%) level of binding to wheat-germ ribosomes was reduced even further when residual linear molecules were eliminated from the circle preparation (Fig. 5*b*, open circles). Even after fixation with glutaraldehyde, binding of circular poly(A, U, G) to wheat-germ ribosomes could not be detected (data not shown). Poly(A, U, G) circles also failed to form stable complexes with reticulocyte ribosomes (Fig. 3*b*, closed circles). In contrast, circular poly(A, U, G) attached to *E. coli* ribosomes (Fig. 5*d*) even more efficiently than the corresponding linear template. The reasons for the enhanced binding of circular templates, and for accumulation of some of the circular poly(A, U, G) molecules in 30S complexes, are not known.

The validity of the control experiments with *E. coli* ribosomes requires that the circular polymers are not nicked by endonucleases which might contaminate the *E. coli* translational system. Three observations suggest that circular RNA templates were not converted to a linear form before binding. (1) As mentioned previously, circular pUpG(pA)$_{25}$ failed to bind to *E. coli* (as well as to wheat-germ) ribosomes, presumably due to the small size of the circles. The same polymer preparation was able to attach to *E. coli* ribosomes after cleavage of the circles with T_1 RNase. Thus, the level of endonuclease activity associated with *E. coli* ribosomes was apparently insufficient to convert circular pUpG(pA)$_{25}$ to a linear form. (2) The pattern of binding of poly(A, U, G) circles to *E. coli* ribosomes was qualitatively different from the binding of linear poly(A, U, G). That is, a large proportion of the circular molecules accumulated in 30S complexes. Although the reason for this is not known, the different binding patterns obtained with linear and circular poly(A, U, G) suggests that the circular molecules were not cleaved during the incubation. (3) Attachment of both linear and circular poly(A, U, G) templates to *E. coli* ribosomes was complete within 2 min of incubation. The rapid binding suggests that conversion of circular molecules to a linear form is not a prerequisite for attachment to *E. coli* ribosomes.

The present experiments suggest that eukaryotic ribosomes might thread on to the 5′-end of mRNA. Even in the absence of the m^{7}G cap, the 5′-terminus of mRNA apparently has an essential role in ribosome attachment, as circularisation of pUpG(pA)$_{40-80}$ or of poly(A, U, G) totally abolished ability of the template to bind to wheat-germ or reticulocyte ribosomes. It seems unlikely that the size of the circles restricts their ability to interact with eukaryotic ribosomes. Although the small size of the pUpG(pA)$_{25}$ circle preparation may have precluded interaction with ribosomes, the larger pUpG(pA)$_{40-80}$ circles also failed to bind to wheat-germ or reticulocyte ribosomes. In the case of the circular poly(A, U, G) preparation used in Fig. 5, most of the molecules were more than 80 nucleotides long. Other trivial explanations for the inactivity of circular templates with eukaryotic ribosomes seem to be ruled out by two controls: (1) linear forms of each polymer were able to form initiation complexes in wheat-germ and reticulocyte extracts; and (2) the circular molecules that failed to bind to wheat-germ or reticulocyte ribosomes were able to bind to *E. coli* ribosomes. The striking difference in activity of circular templates with bacterial and eukaryotic ribosomes supports the suggestion[1] that the mechanism by which eukaryotic ribosomes select initiation regions in mRNA seems to be quite different from that of prokaryotes.

If mRNA threads through an aperture on the 40S ribosome, one might anticipate that the 40S subunit would be unable to detach when the ribosome arrives at a termination codon. Following release of the 60S subunit and the nascent polypeptide, the 40S subunit might remain on the message until it reaches the 3′-terminus. An alternative possibility is that the aperture through which the message threads is formed by the junction of the 40S subunit with initiation factor(s), which detach after mediating the early steps of translation.

I thank Dr Joan Steitz for suggesting circular templates for these studies, Joanne Meddick for technical assistance, Dr Aaron Shatkin for comments on the manuscript and Dr W. Szer for providing *E. coli*. This work was supported by NIH grant AI 15242.

Evidence that *Euglena* chloroplasts do not export tRNAs

THE chloroplastic (Chl) and mitochondrial genomes from various organisms contain 20–30 tRNA cistrons. Several reports have demonstrated the presence of 20–30 tRNA species in these organelles. Thus, both chloroplasts and mitochondria seem to contain at least one tRNA species for each amino acid, plus initiator $tRNA^{Met}$ and a few isoacceptors[1–7]. In the few cases so far examined[1,8], organelle tRNAs have been shown to have primary sequences differing from those of their cytoplasmic isoacceptors. Three laboratories have demonstrated that *Euglena* Chl DNA codes for 22–26 species of $tRNA$[9–11]. In the report of McCrea and Hershberger[11] total cellular tRNA was separated into two fractions (I and II) by diboryl DEAE (DBAE) cellulose chromatography. Fraction I hybridised with both nuclear and Chl (~18 cistrons) DNAs. Fraction II seemed to hybridise only with Chl DNA (7–9 cistrons). Fraction II tRNA was not detected in isolated chloroplasts[11], but was found in either total cellular or cytoplasmic polysomal RNA[12], and contained acceptor activity for eight amino acids (Ala, Arg, Glu, Gly, Leu, Lys, Met and Phe)[12]. As fraction II tRNAs hybridised with Chl DNA but were not found in isolated chloroplasts it was proposed that although they were transcripts of the Chl genome they were selectively exported to the cytoplasm[11,12].

In our laboratory chloroplast-localised tRNAs of *Euglena* have been identified by chromatographic comparisons with either total cellular tRNA or tRNA isolated from mutants lacking Chl DNA[1]. For each of 16 amino acids studied, isolated chloroplasts were found to contain unique chromatographic species of tRNA[1]. tRNA from isolated chloroplasts is complementary to 26 tRNA cistrons and Chl $tRNA^{Phe}$ and $tRNA^{Asp}$ are coded for by one cistron each[9]. In this report, we show that tRNAs obtained from isolated chloroplasts or whole cells hybridise to Chl DNA to the same extent and competition experiments reveal that these two sources of Chl tRNA complement identical cistrons. Furthermore, chromatographic evidence is presented that all the tRNA species represented as being totally exported to the cytoplasm[12] exist in isolated chloroplast preparations (which show no cytoplasmic contamination). These data indicate that there is no detectable transport of Chl tRNAs to the cytoplasm.

The tRNAs from whole cells and isolated chloroplasts were iodinated *in vitro*[9]. The amount of DNA complementary to each tRNA at infinite concentration was determined using double reciprocal plots (Fig. 1). Total cellular tRNA and tRNA from isolated chloroplasts are complementary to essentially the same percentages of Chl DNA (0.73% and 0.69, respectively). These data agree with our previous report[9] that 0.74% of the Chl genomes hybridises with tRNA from isolated chloroplasts. Thus, tRNA from either source is complementary to 24–26 cistrons. Competition experiments were also carried out to verify that both total cellular tRNA and tRNA from isolated chloroplasts hybridised with the same portions of the Chl genome. A constant amount of total cellular ^{125}I-labelled tRNA was hybridised with Chl DNA in the presence of increasing amounts of unlabelled tRNA from either whole cells or isolated chloroplasts (Fig. 2). Both sources of tRNA are equally effective as competitors; over 90% of the hybridised counts could be competed for by the addition of unlabelled tRNAs. On a weight basis, tRNA extracted from isolated chloroplasts is a more effective competitor than tRNA from whole cells, because only ~35% of the total cellular tRNA is chloroplastic[9]. Thus, both whole cells and chloroplasts seem to contain an identical complement of Chl DNA-coded tRNAs.

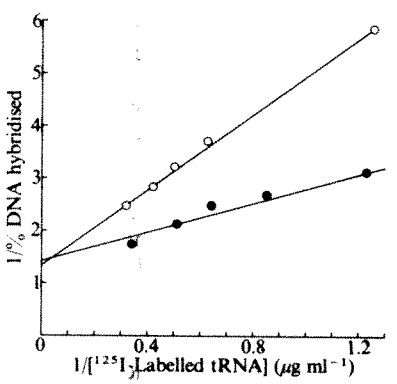

Fig. 1 Double reciprocal plot of the hybridisation of Chl tRNA (○) and total cellular tRNA (●) to Chl DNA. Filters containing 0.25 μg of Chl DNA were hybridised with Chl ^{125}I-labelled tRNA (9.7×10^6 c.p.m. per μg) or total cellular ^{125}I-labelled tRNA (1.4×10^7 c.p.m. per μg) in the presence of a fourfold excess of Chl rRNA as described previously[9]. At infinite concentrations of tRNA, 0.73% and 0.69% of Chl DNA is complemented by total cellular and Chl tRNAs, respectively.

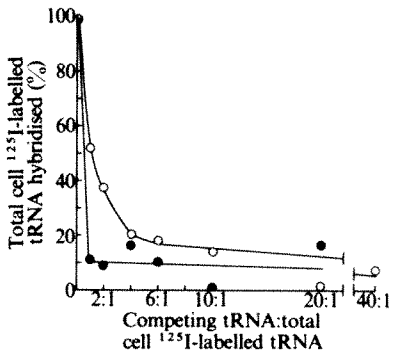

Fig. 2 Competition between Chl tRNA and total cellular tRNA for hybridisation with Chl DNA. Saturating concentrations of total cellular ^{125}I-labelled tRNA (9.4×10^7 c.p.m. per μg) were hybridised with filters containing 0.25 μg Chl DNA and increasing amounts of unlabelled total cellular (○) or Chl (●) tRNAs. All vials contained unlabelled Chl rRNA.

Although McCrea and Hershberger reported [12] that fraction II tRNA contains acceptor activity for eight amino acids, previous reports have demonstrated that chloroplasts contain a unique species of $tRNA^{Phe}$ (refs 13–16) and Kislev *et al.*[17] demonstrated that *Euglena* chloroplasts contain acceptor activities for at least 16 amino acids including all those present in fraction II tRNA. Furthermore, we have been able to demonstrate (using BD-cellulose chromatography) that for each amino acid acceptor activity reported to be present in fraction II $tRNA$[12] a chromatographically unique species is present in isolated chloroplasts. Examples of this are shown in Fig. 3 for $tRNA^{Ala}$ and $tRNA^{Arg}$. Isolated chloroplasts contain only a single symmetrical peak of alanyl and arginyl acceptor activity, whereas tRNA from whole cells has an additional isoacceptor for each of these amino acids. In whole cell preparations, Chl $tRNA^{Ala}$ elutes as a trailing shoulder of the cytoplasmic isoacceptor and Chl $tRNA^{Arg}$ also elutes later than its cytoplasmic counterpart. There is no evidence for the existence of any tRNA species in any case other than those from isolated chloroplasts or from the cytoplasm (nuclear coded).

The results presented here and those in many other reports are inconsistent with the hypothesis that the chloroplasts of *Euglena* selectively export a specific class of Chl-coded tRNAs that may be found in the cytoplasm or cytoplasmic polysomes[11,12]. In the absence of chromatographic characterisation of the tRNA isoacceptors found in their DBAE-cellulose, cytoplasmic polysomal, total cellular or Chl fractions it is difficult to explain the results of McCrea and Hershberger.

Mutants lacking Chl DNA, and thus unable to code for Chl tRNAs, exhibit normal growth and are still able to synthesise all chloroplast-localised (nuclear-coded) enzymes so far examined[18]. Thus, there seems to be no physiological need for

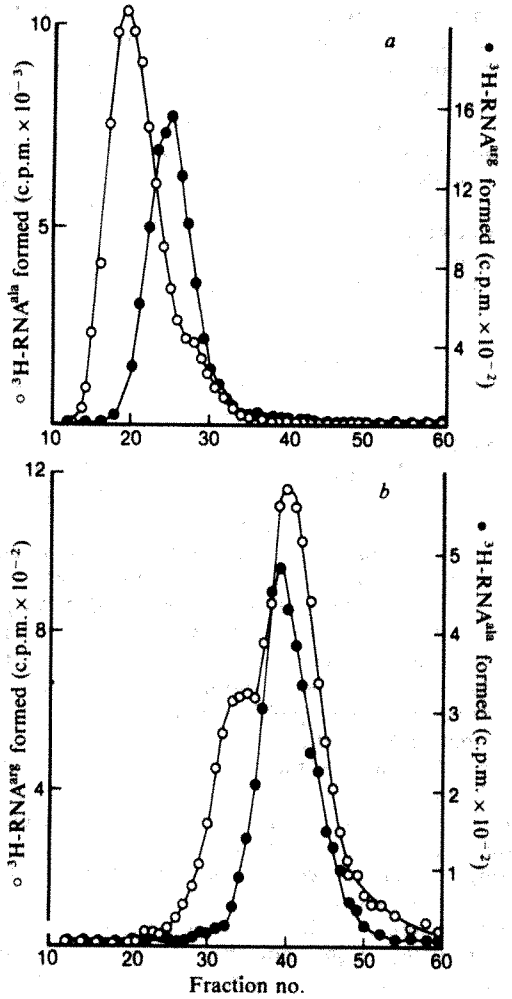

Fig. 3 Benzoylated-DEAE cellulose chromatography of total cellular (○) and Chl (●) deacylated tRNAs. 200 A_{260} units of tRNA from purified chloroplasts or 300 A_{260} units of tRNA from whole cells were applied to a 1 × 21 cm column and eluted with an 800-ml linear gradient from 0.33–1.25 M NaCl (ref. 16). Ala (*a*) and Arg (*b*) acceptor activities were assayed as previously described for Phe[16,18] with the exception that the buffer used was HEPES, *p*H 7.5.

exported tRNAs as either constitutive or regulatory components of the cytoplasmic translation system. Therefore, we conclude that all evidence for the export of Chl DNA-coded tRNAs from chloroplasts is of doubtful significance.

Molecular basis for proton-dependent anion binding by soybean leghaemoglobin *a*

HAEM proteins are widespread in nature and exhibit diverse biological activities. The properties and function of a given haem protein depend critically on the environment of the haem group. The reactivity of the haem is often influenced by one or more haem-linked ionisable groups. Thus, oxygen affinities of mammalian haemoglobins, for example, exhibit considerable *p*H dependence (the Bohr effect[1]). Anion binding to some haem proteins is also a proton-dependent reaction (for example, peroxidase[2], catalase[2] and leghaemoglobin[3,4]) whereas for others (myoglobin, haemoglobin[1]) it is essentially independent of *p*H. Identification of the ionisable groups which influence the ligand-binding reactions of haem proteins is of fundamental importance in the elucidation of structure/function relationships. Nuclear magnetic resonance (NMR) spectroscopy is one of the most direct methods for observation of titrating groups in proteins. We report here on NMR studies of the nicotinate complex of soybean ferric leghaemoglobin *a*. On the basis of these studies we propose a role for a haem propionic acid group as a mediator of anion binding.

All experiments were carried out with soybean ferric leghaemoglobin *a* prepared by a previously described procedure[5]. Reactions with acetate to form a high-spin complex[3] and nicotinate to form a low-spin ferric complex[4] are proton dependent, with *p*K values of 4.8 and 4.9, respectively. The affinity of leghaemoglobin for these anions increases with decreasing *p*H, suggesting the presence of a haem-linked ionisable group which, when protonated, facilitates access or binding of anions to the haem.

The low field region of the proton NMR spectrum of ferric leghaemoglobin nicotinate is shown in Fig. 1*a*. Resonances in this region of the spectrum are subject to large hyperfine shifts due to the presence of the single unpaired electron of the iron atom and generally arise from protons on the porphyrin ring or axial iron ligands[6]. The resonances are relatively narrow due to the rapid electron spin relaxation characteristic of low-spin ferric haem[6]. The resonances at 25.6 and 18.5 p.p.m. at 45 °C and *p*H 4.5 can be unambiguously assigned to two of the four porphyrin ring methyl groups, on the basis of their intensities and previous NMR studies of haem proteins and model haem complexes[6]. The two single proton resonances at 14.9 and 12.7 p.p.m. at *p*H 4.5 are assigned to the two α-CH_2 protons of one of the haem propionic acid side chains. The resonances shift at acid *p*H, titrating with a *p*K of 4.9 (Fig. 2). The assignment is confirmed by the observation of a large negative nuclear Overhauser effect[7,8] (~40%) on each resonance when the other is irradiated (Fig. 1*b*, *c*). The protons are therefore in close spatial proximity such that each dominates the nuclear relaxation of the other, as would be expected for two inequivalent protons of a propionic acid methylene group. Restriction of the rotational motions of the propionate side chain would give rise to magnetic inequivalence of its α-CH_2 or β-CH_2 protons. Assignment is made to the α-CH_2 rather than the β-CH_2 protons on the basis of the larger contact shift experienced by the former. No other protons on the haem or axial iron ligands can give rise to these

0028-0836/79/270087—02$01.00

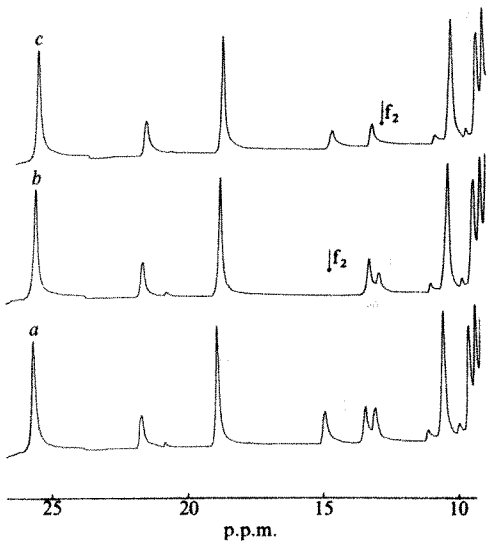

Fig. 1 *a*, Low field region of the 270-MHz proton NMR spectrum of soybean ferric leghaemoglobin *a* nicotinate at 45 °C and *p*H 4.5. *b*, Negative nuclear Overhauser effect (~40%) on resonance at 12.7 p.p.m. due to irradiation at 14.9 p.p.m. *c*, Negative nuclear Overhauser effect (~40%) on resonance at 14.9 p.p.m. due to irradiation at 12.7 p.p.m. Spectra were recorded using a Bruker HX-270 spectrometer operating in the pulsed Fourier transform mode. The residual HOD peak was suppressed by selective gated irradiation. Overhauser effects were measured by selective irradiation which was gated off immediately before data acquisition. Dioxan was used as an internal standard but all peaks are referred to trimethylsilylpropanesulphonic acid. Solutions for NMR were 3–4 mM in leghaemoglobin in phosphate buffer (10 mM, in D_2O). The *p*H was adjusted by careful addition of DCl or NaOD. The *p*H values quoted are uncorrected meter readings.

resonances. We believe this to be the first unequivocal assignment of the α-CH_2 proton resonances of a haem propionic acid side chain in the NMR spectrum of a haem protein. The assignments of the other resonances in the low field region will be published later.

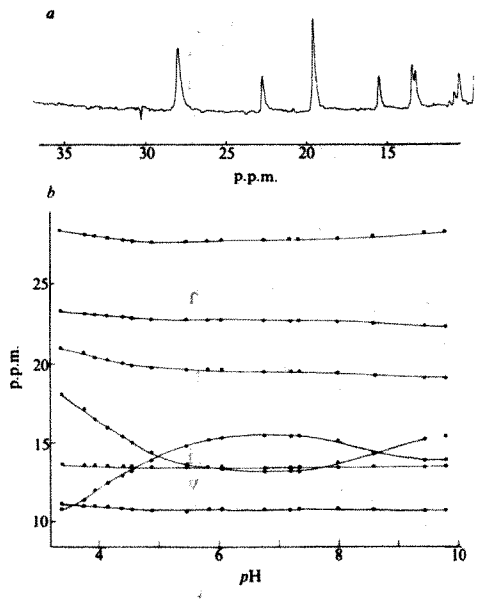

Fig. 2 *a*, Proton NMR spectrum of soybean ferric leghaemoglobin *a* nicotinate at 25 °C and *p*H 7.2. *b*, *p*H dependence of the low field region of the NMR spectrum. Exchange between nicotinate and ferric leghaemoglobin is slow on the NMR time scale. An excess of nicotinate was used such that the leghaemoglobin was fully complexed at *p*H values below ~7.0. At higher *p*H, dissociation of nicotinate leads to a decrease in intensity of the resonances.

Unfortunately, we are unable to assign the resonances of this haem propionic acid side chain in the spectrum of ferric leghaemoglobin acetate. These and the resonances of other protons near the haem are very broad due to the slow electron spin relaxation of the high-spin ferric haem.

The propionic acid resonances in the spectrum of leghaemoglobin nicotinate reflect the titration of two ionisable groups (Fig. 2). As the *p*H is increased above ~7.0 it is evident from the observed decrease in intensity of the low field haem resonances that nicotinate binding becomes weaker. The large perturbations at acid *p*H (Fig. 2) clearly arise from titration of the propionate side chain carboxyl group with *p*K 4.9. A further substantial perturbation is observed above *p*H 7. Its magnitude suggests a close interaction between the haem propionate and a group with *p*K 8.3. We identify this other group as the distal histidine residue, as we can follow the titration of a singlet resonance with *p*K 8.3 as it shifts from 8.1 p.p.m. to ~7.2 p.p.m. with increasing *p*H (unpublished observations). The high *p*K of this histidine is consistent with formation of a salt link or hydrogen bond to the carboxyl group of the nicotinate ligand[9,11].

On the basis of affinity labelling with mesohaem sulphuric anhydride, Ellfolk and Perttila[10] have suggested that one of the haem propionic acid side chains forms a salt bridge to Lys 57 in soybean ferric leghaemoglobin *a* at low temperature. Our NMR studies provide no evidence to support this proposal but indicate an interaction between one of the haem propionates and the distal histidine in leghaemoglobin nicotinate.

The present NMR studies indicate that at least one of the haem propionic acid substituents in soybean ferric leghaemoglobin *a* nicotinate is accessible to the solvent and free to titrate with a *p*K of 4.9. Reactions of the ferric protein with acetate and nicotinate are proton dependent, with *p*K values of 4.8 and 4.9, respectively[3,4]. These *p*Ks correspond closely to that of the free propionic acid side chain, which is thus likely to be the group which mediates anion binding. We thus propose a model for the reactions of soybean leghaemoglobin *a* with anions in which a haem propionic acid group, when deprotonated, functions as an electrostatic 'gate' which restricts the access of anions to the haem pocket. Protonation of this group would facilitate anion binding. In an alternative mechanism access of anions to the haem is sterically hindered as a result of protein conformational changes accompanying deprotonation of the haem propionic acid. This mechanism may be discounted, as reactions of leghaemoglobin with neutral ligands such as pyridine[4] and nicotinamide (C.A.A., unpublished observations) are independent of *p*H.

We thank Mrs J. Wellington for assistance and the Australian Research Grants Committee for financial support and for the use of facilities at the National NMR Centre.

Balanced overview of cancer research

Richard Peto

Cancer, Science and Society. By John Cairns. Pp. 199. (Freeman: San Francisco and Reading, 1979.) Hardback £6.20; paperback £2.90.

THE general public, which provides the money that cancer research consumes, seems to hope for the eventual emergence of the sort of "magic bullet" cancer cure which is as easy, specific and effective as an antibacterial agent can be against infections. In reality, there is little hope of any such thing; indeed, the prospect is so remote that it scarcely enters into the day-to-day conversation of most cancer research workers. Researchers talk of slightly earlier detection, of moderate improvements in current methods of therapy, of the prevention of minor environmental carcinogens, of the identification of life styles (with less meat, less tobacco and lots of vitamins) which would, if only anyone would adopt them, somewhat reduce cancer incidence rates. They talk of developing a greater understanding of tumour antigens or of the nature of the transformed state, but easy and specific cures are not sufficiently realistic to be of interest.

In this book, John Cairns tries to explain the realities of cancer biology and epidemiology in sufficient detail to be interesting and to let the facts themselves give the reader a realistic perspective on "cancer, science and society". In this I feel he succeeds excellently, and anybody with a background in any area of science would enjoy this overview. In style it reminds me of the *Scientific American*; it is clearly written and well illustrated, with separate chapters on each of several completely different areas of research, from demography to biology.

What is perhaps unusual in a book by a professional cancer research worker is his whole-hearted public acceptance of the idea that we cannot expect any "magic bullet" cancer cure to be discovered for at least several decades. Whether this pessimism is justified or not, it is certainly a view which deserves to be more seriously debated than in the past. Obviously, an optimistic claim that understanding viruses, interferon, immunology, and so on, will soon offer specific cures is impossible to refute and, if accompanied by any new finding, will be more newsworthy and therefore more widely published than the pessimistic claim that we are decades away from a detailed enough understanding of cell biology to devise a cancer cure rationally. However, this inevitable emphasis on optimistic perspectives may in the long run produce the sort of distorted hopes of rapid victory that, as with wartime propaganda, is fostered by reporting victories more prominently than defeats. If Cairns is right in his pessimism about the next few decades of cancer therapy, then he is surely right in his inference that *clinical* cancer research nowadays is over-supported, and that the two chief areas of research to foster over the next few decades should be cancer prevention and, at the other extreme, fundamental biological research with no requirement for any obvious connection with cancer. As a strategy, it may well be more successful than seeking vast amounts of money for clinical research with the slogan "Conquer cancer in the seventies".

Whether or not this overall perspective is accepted, the book provides an interesting, readable and balanced overview of cancer research, written for the sort of intelligent general public who perhaps do not know very much about cancer research but who might feel sufficiently interested to read a whole issue of the *Scientific American* devoted to the subject. As an introduction to the subject, it is as good as any I have seen, and would be an excellent textbook for an undergraduate or post-graduate biology course on cancer. However, the people who I chiefly hope will spend a pleasant evening reading it are the cancer research workers who are concentrating on particular details and who need some feel for how (or whether) their activities make sense in a wider context.

The book begins with demography. As a cause of death, cancer was much less important in the nineteenth century, simply because cancer tends to be a disease of old age, and most people never reached old age. However, during the past 100 years life expectancy in developed countries has suddenly doubled, and over 75% of people will now live beyond the age of 65.

Consequently, the present chief cause of death are those which act in old age, the most prominent being vascular disease (half of all deaths), cancer (one-sixth of all deaths) and, in Britain but not America, respiratory disease (another one-sixth). On average, those who die of cancer would only have lived another 12 years if their cancer had been prevented or cured, which is, of course, likely to be a worthwhile gain for the individual if a fair number of those years were passed in reasonable health. However, an average of 12 years extra for one-sixth of the population only represents an additional two years of life expectancy for the population as a whole, and is not comparable with the 30 or more years of extra life expectancy that has been conferred by control of the diseases which used to kill so many children and young adults. (Only 1% of cancers affect children.) In short, even the total prevention or cure of all cancer cannot yield the sort of huge change in the human condition that has followed from adequate nutrition and from the control of the major infectious diseases.

Turning from demography to epidemiology, cancers of different anatomical sites (for example, stomach and lung) behave as different, and largely unrelated, human diseases. Causes of one are unlikely to be causes of the other; a genetic predisposition toward one does not imply an abnormal risk of the other (except in a few people with very unusual genetic defects); and, most importantly, control of one type of cancer does not mean that the age-specific risk from any other cancer need be increased. Thus, there is not one cancer problem but many.

The converse of this rather unwelcome conclusion is that although the total age-specific cancer death rates in different countries tend to be rather similar, this overall similarity is the sum of many widely different parts. Indeed, one of the most encouraging findings in the whole of cancer research is that there exist very great differences between countries in the age-specific risks from particular cancers. (The risk of developing cancer increases so sharply with age that it is often misleading to talk about overall probabilities of cancer, for in poor countries where most people still do not reach old age the net likelihood of cancer is small even if the age-specific cancer risks are normal.) For example, lung cancer is 35 times as common among people of a given age in Britain as among people of that age in

0028-0836/79/270089-02$01.00

© Macmillan Journals Ltd 1979

Nigeria, suggesting that the large majority of our 35,000 annual lung cancers are preventable. Stomach cancer is 25 times commoner in Japan than in Uganda but has been decreasing quite rapidly over recent decades as Japan has adopted a richer, more Western diet. Cancer of the oesophagus is more than 100 times commoner in north-eastern Iran (where it is the major cause of death) than in most other parts of the world, and has apparently been common there for centuries. The general rule is that, although some cancers are rare everywhere, every cancer which is common in one country is rare in another country, and so for every common cancer there presumably exist life-styles which humans would find acceptable that would make it vastly less common, probably without making any other type of cancer much more common. This presumption is supported by what sparse data are available on rapid changes in the age-specific incidence rates of various cancers over the past few decades. In America in 1930, cancer of the stomach was the commonest fatal cancer, whereas cancer of the lung was rare. Nowadays, the opposite is true. Over the same period in Britain, cancer of the tongue has decreased twentyfold, whereas cancer of the lung has increased twentyfold.

Thus, cancers have causes. But what might they be? It is tempting to ascribe them to large-scale chemical pollution of air, food or water, but this is probably mistaken, if only because the widespread dissemination of chemicals (in plastics and agriculture) is too recent for its effects on cancer yet to be apparent. In Britain 30%, and in America 25%, of all cancer deaths can be attributed to smoking, and if those cancers which are closely associated with smoking are omitted there is no upward trend in the overall death rates from the remaining cancers. If smoking accounts for only just over a quarter of all cancer deaths, what preventable causes account for the rest? An unproven but plausible hypothesis ascribes a large role in the genesis of colorectal, breast and endometrial cancer to meat, or fat, consumption; and Cairns presents the visually striking relationship between meat consumption and colon cancer. (Unfortunately, he does not also discuss the interesting hypothesis that certain vegetables or vitamins may be actively protective.)

Cairns then turns his attention to the world of cancer research. It is a rather aristocratic overview ("Biology and cancer research have developed together. Invariably, at each stage the characteristics of the cancer cell have been ascribed to some defect in whatever branch of biology happens at the time to be fashionable and exciting; today it is molecular genetics . . . . "), but tends to be the more interesting for being so.

In order to understand the cancer cell we must be taught something of the chemical basis of heredity, and this is done nicely from first principles, starting with DNA, RNA, the triplet code and the effects of mutations in it. Repair mechanisms are described, and then Cairns is ready to move on to the experimental production of cancers by chemical carcinogens, radiation and viruses. Many of the chemical agents which produce cancers in rodents also turn out to be mutagens for bacteria (or chemicals which can be converted into bacterial mutagens by enzymes which are present in normal mammalian cells). Obviously, this offers the possibility of detecting certain carcinogens quickly by allowing them to act on a mixture of mammalian cell components and bacteria,

Oliver escapes being bound apprentice to the Sweep

Cancer of the scrotum was prevalent in boys not so lucky

and seeing whether they cause mutations in the bacteria. Such methods may, however, be of more use in the prevention of new carcinogens than in detecting those which have already affected us for decades.

The two chapters on the experimental production of cancers are among the best in the book, perhaps because Cairns is here reviewing his own field. Perhaps because I am not, or perhaps because they already represent a greatly condensed account of a great deal of material, I find them difficult to summarise.

The concept of the metabolic activation of relatively inert precursors into electrophilic species that can bind to DNA took a long time to evolve, but it has allowed a grand unification to emerge of the mode of carcinogenic action of a wide class of 'initiating' agents, including chemicals that do and chemicals that do not need metabolic activation, some aspects of radiation carcinogenesis, and even certain viruses which seem simply to cause non-specific damage to DNA. The notable exceptions to this grand unification are the "promoting" agents, which seem to bind only to the surface of the target cell but which can greatly increase the carcinogenic effects of 'initiators', and the specific tumour viruses, which are described nicely in detail.

No virus in its right mind wants to exterminate its host; viruses just want to make sure that host animals continue to excrete enough virus particles throughout their lifespan to make them infect all their acquaintances. The best way to do this is for the virus to insert its genetic material into the DNA of the host's own germ cells or, failing that, the host's tissues, in such a way that copies can be run off whenever necessary. In the process, the virus may by mistake trigger certain host cell functions which make the host cell behave like a cancer cell, but from the virus's point of view that is an expensive mistake, as it kills the host. Alternatively, a really unfortunate virus may when it releases its own genetic material from the host's material inadvertently include a little bit of host DNA containing an instruction which, if expressed without proper host control, could cause uncontrolled proliferation. Without the advent of cancer research workers (who are pleased to discover and to selectively propogate such oddities), such viruses would be at an evolutionary dead end, and their non-sarcomagenic cousins, who could live in hosts without killing them, would meekly inherit the earth.

In short, Cairns is not sure which, if any, of the known tumour viruses are laboratory artefacts, perhaps useful as tools for controlledly manipulating and studying the 'transformed state' *in vitro* but not as models of human carcinogenesis.

Nor is he sure, of course, what the essential attributes of the "transformed state" are; it seems as though the key tricks needed to grow the cells one really wants to study have still not been found. If, as is often done, we define 'transformation' as the ability to grow indefinitely in soft agar, 'transformed' cells will indeed usually develop into a tumour when transplanted into a host. However, cells from real human tumours will usually not grow at all in soft agar or in any other *in vitro* conditions yet tested, and moreover normal human cells growing *in vitro* are almost impossible to 'transform', so most studies of transformation are done with rodent cells. These 'transform' spontaneously, or in response to viruses, chemicals or radiation, but although the biochemistry of transformation is currently being elucidated, its relevance is not yet clear.

Returning to matters which are better understood, the many decades that may elapse between the action of an initiator and the eventual emergence of a carcinoma are discussed in terms of multistage models, emphasising the relevance of such ideas for early detection programmes. The final chapter on prospects for the future is almost too pessimistic about whether preventive measures, even if discovered, will be implemented, and emphasises very strongly the improbability of discovering any simple, effective and specific cancer cure in the foreseeable future. □

Richard Peto is Reader in Cancer Studies at the University of Oxford, UK.

Announcing

Journal of Virological Methods

Editor-in-Chief
A.J. ZUCKERMAN
Department of Medical Microbiology
London School of Hygiene and Tropical Methods
Keppel Street
London WCIE 7HT
U.K.

Aims and Scope

The Journal of Virological Methods will publish original papers and invited reviews covering techniques on all aspects of virology. These will include methods for studying the morphology, assembly, replication, composition, function and physiochemical properties of viruses and their components; the purification of viruses and their components; cultivation; properties of viral antigens, production of antibody and techniques for studying the immune response to virions, viral subunits and components; the detection and identification of viruses and viral infections; assay of viruses and viral infectivity and the investigation of transmission and pathogenicity; and methods for investigating the suppression or inhibition of viral growth.

MARC

FOUR NEW REPORTS from MARC

Assessment of risk from persistent pollutants

The emission of pollutants which persist in the environment is committing mankind to some inevitable future harm. There is growing opinion that in many such cases the degree of harm is proportional to the exposure and that there is no exposure threshold below which absolute safety occurs. In these situations, the global collective 'exposure commitment' is a measure of the total resulting harm wherever and whenever it may occur.

The calculation of this exposure commitment is a powerful tool in assessing the potential harm from past, present and likely future polluting activities. The commitment approach has already been applied by the United Nations Scientific Committee on the Effects of Atomic Radiation to radioactive pollutants and has contributed to the development of international policy relating to their control.

During the past three years, MARC has been developing this method and applying it to non-radioactive, persistent and globally important pollutants such as lead and mercury. In the new series of reports listed below, the basic principles and formalism underlying this approach are given, its application to lead and mercury by use of existing monitoring and research data is illustrated and the major gaps in available data are highlighted. These reports represent the foundations upon which further work in this and related fields is currently being carried out at MARC.

MARC Report No. 12
An introduction to the exposure commitment concept with reference to environmental mercury. Approx. 40 pp (plus annex 50 pp)
The exposure commitment approach is introduced on an elementary, applied basis. The pollutant transfer analysis for several pathway configurations is presented, showing the relationships to first order kinetic modelling. The methods are illustrated by considering the release of mercury into the environment from natural and man-made sources. ISBN 0 905918 11 8 Price £2.00 ($4.00)

MARC Report No. 13
The exposure commitment method with application to exposure of man to lead pollution. Approx. 45 pp (plus annex 20 pp)
The mathematical basis for the exposure commitment method is presented including the use of pollutant transfer functions in environmental compartment modelling, exposure and intake commitments, and consideration of chemical transformations, non-well-mixed compartments and exposure times. Using data from the literature, the exposure commitments from the transfer of lead in the environment to man via inhalation and ingestion pathways are evaluated and compared. ISBN 0 905918 12 6 Price £2.00 ($4.00)

MARC Report No. 14
Atmospheric transport of mercury: exposure commitment and uncertainty calculations. Approx. 40 pp
A compartment model for mercury transport in the environment is developed. Compartment sizes and transfer rates estimated for assumed release rates of mercury into the environment from natural and man-made sources. Estimates are made of present and future equilibrium levels. Exposure commitments to the various compartments of air, soil and water are calculated. Methods of error analysis of the results are discussed. Sensitivity analysis indicates the major sources of error in the calculations and suggests important parameters for monitoring. ISBN 0 905918 13 4 Price £2.00 ($4.00)

MARC Report No. 15
Kinetic and exposure commitment analyses of lead behaviour in a biosphere reserve. Approx. 36 pp
An evaluation is presented of data on lead collected as part of a multimedia monitoring programme in the protected natural background area of the Great Smoky Mountains Biosphere Reserve in the U.S.A. A compartment model is formulated with transfers occurring between vegetation, forest litter, soil, heterotrophs, surface water and ground water. The equilibrium concentrations inferred from the model are compared with the field data. Transfer coefficients are estimated from the equilibrium concentrations. Once these are obtained, the consequences (exposure commitments) of a given input of lead into the system can be determined. ISBN 0 905918 14 2 Price £2.00 ($4.00)

For further particulars, or to order, contact the Monitoring and Assessment Research Centre (MARC), The Octagon Building, 459A Fulham Road, London SW10 00X. Telephone 01-351 3577 Telex 915407. Price £2.00 ($4.00) each or £7.00 ($14.00) the set of four. Limited print order. Publication September 1979.

GENERAL RELATIVITY AND COSMOLOGY
Professor J.V. Narlikar

A critical analysis of General Relativity as applied to Cosmology written by one of the worlds leading astrophysicists.

It presents a thorough survey of current cosmological theories, including a brilliant examination of recent controversies and a lucid exposition of the authors own contributions to the field.

This is a pioneering work which will bring the reader up-to-date with developments made in a field which has been increasingly active since Einstein first proposed his General Theory of Relativity.

Contents:
Theories of gravitation – Vectors and Tensors – Tensor Calculus – Space-time Curvature – Space-time Derivatives – Energy-momentum Tensors – The Einstein Equations of Gravitation – The Schwarzchild Solution – The Experimental Tests of General Relativity – Strong Gravitational Fields – Cosmology – The Friedmann Models – The Steady State Theory – Observational Tests in Cosmology.

Discrete charges in quantum mechanics

Gravitation, Electromagnetism and Quantized Charge: The Einstein Insight. By Daniel M. Pisello. Pp. 94. (Ann Arbor Science: Ann Arbor, Michigan, 1979.) Distributed in UK, Africa and Europe by Wiley: Chichester, UK. £7.55.

BY means of dogmatic pronouncements on the limitations of human imagination and language, the quantum mechanical philosophy effectively takes away from the younger physicists their right to question and create. If one finds it necessary to question or theorize beyond the restraints so successfully built into the quantum mechanical rationale, one is then, by fiat, pejoratively considered a revolutionary". Thus ends Mr Pisello's thin treatise, half philosphical, half mathematical, and always bitter. This work will not revolutionise physics, "pejoratively" or otherwise. The book's interest, however, lies in the way its author attempts to link his philosophical and political attitudes with a mathematical search for a purely field theoretical approach to the existence of discrete charges in quantum mechanics. The result is an exercise in topology elevated to the rank of "unified theory" through a casual parallel with Einstein's own epistemological objections to the theory of quantum mechanics.

The first three chapters present the conceptual difficulties arising from scientific breakthroughs like the theories of special relativity, general relativity and quantum mechanics. Old and new concepts which apparently contradict each other are reviewed, the limitations inherent in the use of a language created within an earlier framework are discussed, and the need for a "principle of complementarity" is challenged on philosophical grounds. A rapid analysis of the double slit experiment for which "neither linear wave nor discrete particle interpretation provides an adequate representation of the transfer of energy from source to detector" is used to justify searching for the "basic nature of the field variable". The remainder of the book is devoted to this search in the form of mathematical exercises in homotopy theory and general relativity. It ends with a succinct theory of charge as a counting procedure for "an identifiable number of separate left- and right-hand doughnuts".

Noticing that physical field theories deal only with continuous entities while the physical world displays basic discontinuities (the elementary electric charge of the electron being the one specific case considered here) is not new, but the whole preoccupation with continuity, infinities and singularities is indeed continuing. In this sense Mr Pisello's book is part of the contemporary mood. To try to save continuity by hiding the "inside" of particles into topology has been done with mastery by Professor John Wheeler creating "wormholes" for the delight of many students of general relativity. Mr Pisello attempts something similar but each piece of his puzzle unfortunately remains physically and also mathematically quite disconnected. At the Einstein centennial celebration at UNESCO in Paris a few weeks ago, Professor Dirac stressed his own dis-satisfaction with quantum mechanical calculations for which we "learned to turn a disinterested eye to infinities" and urged that Einstein's objections to quantum mechanics be seriously considered anew. Mr Pisello does just that in so far as he retakes "Einstein's insight" in the direction of unified field theories. He fails, however, to display a satisfactory theory, thus joining many others in this particular domain. The author also clearly shares with Einstein a socialist point of view upon the world; this does not justify the bloated language used by the publishers in the presentation of the book: "Pisello agrees with Einstein that quantum mechanics is a reactionary theory devised to maintain the mechanical view". Trying to get too close to Einstein, you may burn yourself up.

Failing to present clearly physical ideas and political analysis may be a consequence of the deep social frustrations experienced by Mr Pisello's generation of physicists. Trained in high energy particle physics, they got their degrees in America at the time of the Vietnam war. Their belief in 'pure' science was shaken when many of their peers were exposed as direct advisors for the US Department of Defence, and they could not get steady work as physicists in a tight competitive job market. This generation of physicists remains anxiously in search of the social and historical connections of scientific work.

Maurice Banzin is Visiting Professor of Physics at the University of Campinas in Brazil.

Sociology of science

Science and the Sociology of Knowledge. Controversies of Sociology. Vol 8. By M. Mulkay. Pp. 132. (George Allen & Unwin: London, 1979.) £7.50; paperback £3.50.

FROM the time of the 'founding fathers' of sociology in the nineteenth century, sociologists have been interested in the way in which bodies of knowledge are influenced by the social and cultural contexts in which they are produced. This is the sociology of knowledge. But scientific knowledge was always seen as something apart, special, and essentially independent of external social influences in a way that was not true of other specialised bodies of thought and knowledge. Thus, when a sociology of science emerged, and developed (quite rapidly from the 1950s), it became something other than the attempt to explain the content of scientific knowledge in terms of social structures and processes. The sociology of science developed as the attempt to understand the social conditions which made scientific progress possible: that is, it was concerned with general social and political conditions (giving rise to the idea of correspondence between science and democracy), as well as with the way in which scientific communities worked. There was a lot of interest in the 'normative structure' of science: the rules or moral code governing the ways in which scientists worked and interacted with each other.

A good deal of work in sociology of science is still being done along these lines, some of the most interesting of it concerned with the emergence and functioning of scientific communities in smaller or less industrialised nations. But Michael Mulkay is concerned with something else. His argument is that both this approach as well as discounting of the possibility of a sociology of scientific *knowledge* are founded upon a particular philosophical view of the nature of science, which he calls "the standard view of scientific knowledge". Roughly speaking, this posits a real, objective, and uniform natural world; it assumes that science, through unbiased and detached observation, can formulate laws of nature which describe this world; that science makes use of entirely objective criteria for evaluating knowledge claims, such that science is ultimately free of bias; and that theoretical laws are of a different status to empirical ones and stand in a quite different relationship to the natural world. He goes on to argue that this philosophy of science is no longer acceptable, and that it is therefore legitimate to try to establish a sociology of scientific knowledge.

Mulkay characterises the "new philosophy of science" as showing the dependence of all observation on theory, of all factual statements on (arbitrary) linguistic frameworks. All meaning in science becomes the product of negotiated agreement and is embeded in some changing framework of values and assumptions. Feyerabend's "epistemological anarchism" is an extreme version of all this.

There have now been a few sociological studies of science which made use of this relativised version of science, and Mulkay describes some of them. It becomes important to try to understand how scientists 'negotiate' 'what counts' as the

0028-0836/79/270091-02 $01.00

© Macmillan Journals Ltd 1979

replication of an experiment (for example). Other work has explored, most interestingly, the way in which scientific disputes are conducted, and the way in which all kinds of political resources and non-scientific opinion can be used.

The final part of the book deals with the exchanges between science and other aspects of culture. This includes the use which may be made of theoretical perspectives or forms of explanation available in general thought. Unfortunately there is little discussion of the conditions under which these will be drawn on.

This whole undertaking is relatively new in sociology, and one cannot yet say what it will yield. My own view is that there are more new philosophies of science than Mulkay implies and that there will gradually emerge many attempts at quite different sociologies of scientific knowledge. Certainly the work which has been done so far is interesting, and could give sceptical scientists pause for thought. The book is likely to be of interest mainly to those who have already read into the field of sociology of science. **Stuart S. Blume**

Stuart S. Blume is Senior Research Fellow in the Department of Social Science and Administration, London School of Economics, University of London, UK.

Mysterious Solar System

Mysterious Universe: A Handbook of Astronomical Anomalies. By W.R. Corliss. Pp. 710. (The Sourcebook Project: P.O. Box 107G, Glen Arm, Maryland 21057, 1979.) $15.95; £8.

MYSTERIES fascinate me and this book contains an abundance. It is a classical "What done it?" — the inanimate scientific relation to the "Who done it?". William R. Corliss has scoured a host of scientific journals for reports of astronomical oddities and has assembled over 500 short articles and extracts, on a multitude of subjects ranging from aurorae in comet tails to zodiacal light-rifts and black and white holes to X-ray bursts.

It is strong meat. Taken at one go the unceasing succession of anomalies, unknowns, mysteries and strange sightings leave the reader mentally punch drunk. You will stagger from the chair to the window to reassure yourself that the Sun and planets and bright stars are still where you thought they should be and have not all capriciously shuffled themselves. But in short bursts the book is a joy and the reader's mind is continually accelerated away in pursuit of ideas and possibilities that may account for the strange events being described.

The timespan covered by the book is reasonably broad, the most up-to-date extracts coming from mid-1978. Approaching from antiquity the number of articles verses time curve increases sharply around the middle of the 19th century, a time which seems to be governed more by the birth of journals such as *Nature* and *Scientific American* than by a sudden onset of mysterious happenings or human curiosity. Our excitement over the 'recent' discovery of the rings of Uranus pales somewhat when we read that Challis and Lassell reported an observation of a ring in 1847. These gentlemen also observed a ring around Neptune.

And things disappear in astronomy too. Vulcan the supposed intra-Mercurial planet sprang into prominence in 1876 only to fizzle from view in the early 1900s. Corliss collects together 14 papers on this subject. We are also introduced to Neith the lost satellite of Venus. The eighteenth-century observations of this object remain enigmatic and simply accumulate distain as they become eroded by time. We can easily smile condescendingly and talk about 'ghosts' in ancient telescope eye pieces but maybe...

Any collection of articles has the character of the collector strongly imprinted on it. This I'm sure cannot be avoided. Corliss shows a strong bias towards the Solar System. For example, the Moon, meteors and meteorites take up 26% of the book, the same amount of space as all the stars, the Sun, galaxies and cosmology put together. A similar percentage is taken up by the planets, leaving the zodiacal light, comets, planetary regularities and the environs of planet Earth to absorb the remainder.

I would be happier if the title of the book was *Mysterious Solar System*. Failing this, there are an enormous number of mysterious star types, stellar origin and evolution problems, interstellar, galactic and intergalactic matter and composition anomalies that could have been expanded to give the book a more 'universal' balance.

However, as a sourcebook of a lot of strange Solar System happenings and a number of stellar and galactic ones, the book is to be highly recommended. It has been well produced, extremely well indexed and is excellent value for money.

David W. Hughes

David W. Hughes is Lecturer in Physics and Astronomy at the University of Sheffield, UK.

Simple classical vibrator

The Physics of Vibration. By A. B. Pippard. Vol. 1. (Cambridge University Press: Cambridge, London, New York and Melbourne, 1978.) £22.50.

THIS is the first volume, devoted to the simple classical vibrator, of a work on the physics of vibration. It is designed to bridge the gap between undergraduate textbooks on the subject and specialist treatises. It ranges widely, discussing not only the obvious examples from mechanics, elementary electronics and acoustics, but also nuclear magnetic resonance, cyclotron resonance and Josephson junctions. The subsequent volume or volumes will deal with specifically quantal pheonomena and with vibrations of complex systems.

There is an introductory chapter describing very clearly the scope of this work; a chapter on the free vibrator; two chapters on applications of complex variables and on Fourier methods; three chapters on spectrum analysis, on the driven harmonic vibrator, and on waves and resonators; then one on volocity dependent forces groups, together with various examples such as whirling, the gyro-pendulum, nuclear magnetic resonance, cyclotron resonance and helicons. This chapter somewhat breaks the flow of the rest of the book, and does not fit in very happily; I am not convinced that this level of treatment of magnetic resonance will be helpful either to the expert or to the inexpert. A chapter on the driven anharmonic vibrator discusses subharmonics and stability. There is a short chapter on parametric excitation and a chapter on maintained oscillators. The final chapter is on coupled vibrators, and includes the Huygens phenomenon, frequency-locking and superconducting weak links.

Although the majority of examples are taken from electric circuit theory and mechanical oscillators, there are many others, some quite intriguing. The level of discussion is what one would expect from a good experimental physicist. The main interest in in common patterns of behaviour rather than in the details of operation, yet the details are worked out for many special cases.

I think that is primarily a book for the teacher rather than for the student. It does not treat any one subject in sufficient detail to be a useful source for someone who really wants to understand it, but it is more detailed than most students who want a general impression of the subject would want. It is, however, full of valuable new insights and analogies which should be helpful to anyone who needs to teach this sort of material. No physics library should be without a copy.

D. J. Thouless

D. J. Thouless is Professor of Applied Science at Yale University, New Haven, Connecticut.

newly on the market

Pressure transducer. Hewlett-Packard. An extremely durable pressure transducer weighing only 30 g has been developed by Hewlett-Packard. It features quartz crystal sensors to measure patient's blood, gastro-intestinal, intrauterine, intracranial and other physiological pressures. With a flat, rather than cylindrical body the transducer is also easier to attach to a patient's limbs. A disposable dome, which attaches with a simple twist-and-lock motion, provides protection against physical damage. Being constructed from a transparent plastics material, nursing staff can easily check to see and dispel any unwanted bubbles which could distort the measurement results. Standard couplings are used so that the transducer, designated HP129OA, may be used with any Hewlett-Packard pressure amplifier. It measures only 3.5 in by 1.25 in and comes complete with six disposable domes.
Circle No. 77 on Reader Enquiry Card.

Hewlett-Packard pressure transducer

Isoelectric focusing system. Bio-Rad. The Model 1415 horizontal electrophoresis cell from Bio-Rad is designed for electro-focusing applications, immunoelectro-phoresis, DNA electrophoresis, and zone electrophoresis. The cooling platform is 43 cm long and enables the user to perform two preparative electrofocusing runs simultaneously in 20-cm gel trays. The lid of the cell contains a series of small holes to enable the user to check the *p*H along the length of the gel without interrupting the current. A cooling coil attached to the perimeter of the lid ensures preferential condensation on the coil rather than on the lid above the gel tray or plate. The techniques developed by Bio-Rad for electrofocusing introduce new methods for drying the granulated bed gel and locating the protein bands on the completion of the run.
Circle No. 78 on Reader Enquiry Card.

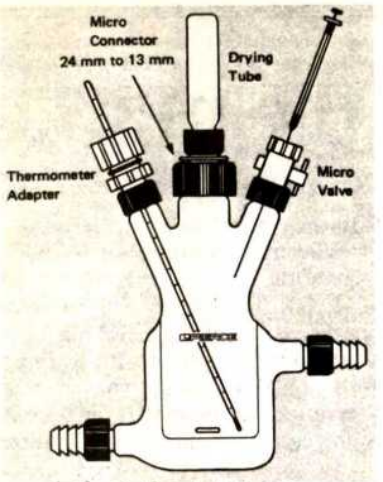
These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Ultramicrotome. Du Pont. Featuring microprocessor control for enhanced operator convenience, the Sorvall MT5000 ultramicrotome has been introduced by Du Pont. It combines reliable cutting precision with operating simplicity for preparation of sections for electron microscopy. Features include: Microprocessor logic for improved accuracy and reproducibility; a Visutrac system for pgrogramming cutting duration; a jog function for precision approach; a built-in anti-vibration system. The MT5000 provides cutting speeds from 0.1 mm s^{-1} to 39.9 mm s^{-1}, with a fast return of 10 mm s^{-1} in the normal sectioning range below 10mm s^{-1}.
Circle No. 79 on Reader Enquiry Card.

Non-destructive testing system. Elomag. A completely new, optical, non-destructive testing system from Elomag permits a wide variety of measurements to be made in engineering and science. A large freestanding optical tripod supports the main elements of the system including: (1) A double laser speckle camera which is used for non-destructive stress, vibration, and flaw analysis of engineering components. (2) The image derotator, that allows precise, live, continuous measurements to be made on rotating objects and fluids. And (3), a compact pulsed ruby laser, that incorporates a q-switch and is used, in conjunction with the other elements of the system, to study dynamic events. The system is self-contained, easy to operate, and portable.
Circle No. 80 on Reader Enquiry Card.

Temperature safety controllers. Neslab has developed temperature safety controllers for constant-temperature baths and circulators covering a range of —85°C to +150°C. The safety controller will shut the entire bath system down and sound a buzzer if a pre-set temperature exceeds ±20°C. Simply plug your bath into the TSC, place the sensor in the fluid, and the unit is ready for operation. The Neslab TSC is an independent control system that can be used with all Neslab bath circulators as well as other manufacturers' baths.
Circle No. 81 on Reader Enquiry Card.

Direct view microscope. Bausch & Lomb. Using the new Bausch & Lomb Balplan Bi*Ocular microscope the magnified specimen image can be viewed in full, natural colour on a 5-inch diameter circular screen. The instrument enables the operator to study specimens in comfort at a magnification of 37.5× to 300× The direct view facility is available on reflected light or transmitted light microscopes.
Circle No. 82 on Reader Enquiry Card.



IR Image converter. Wild Heerbrugg. The new Wild image converter allows binocular observation in the near-IR range of 700–1,200 nm. Images can be recorded with the attachable Leica R3 mirror reflex camera in white light or with IR film. The Wild M 520 IR image converter is for observations in the macro range, but can also be used with microscopes and stereo-microscopes
Circle No. 83 on Reader Enquiry Card.

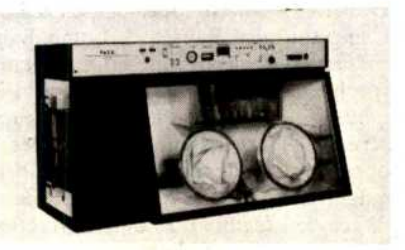
Mycoplasma detection kit. Bioassay Systems. A quick, inexpensive method for detection of mycoplasma contamination has been developed by Bioassay Systems. They have produced a detection kit based on the ability of 4'-6-diamidino-2-phenylindole to form a fluorescent complex with DNA in the mycoplasma. The kit contains a quantity of dye sufficient for 50 assays, a fixed sample of mycoplasma infected cells and a control sample of non-infected cells. The assay requires only 60 min for completion.
Circle No. 84 on Reader Enquiry Card.

Fluorestar microscope. Reichert-Jung. The Fluorestar from Reichert-Jung is a flexible laboratory microscope specifically designed for fluorescence techniques. Facilities are provided for incident light, transmitted light or mixed illumination examinations and all controls are sited to minimise operator fatigue. The incident light fluorescence equipment is very simple to operate. Plug in 'fluo-clusters' are provided with matched exciter filter/dichroic beam splitter/barrier filter combinations. A wide range of optional accessories are available for use with this microscope including camera systems and multi-viewing attachments.
Circle No. 85 on Reader Enquiry Card.

The Reichert-Jung Fluorestar

One of the Pierce jacketed reactors

Multi-purpose jacketed reactors. Pierce. These jacketed reaction vessels offer a wide range of applications in the research laboratory. The reactors feature a central opening to accommodate virtually all combination *p*H electrodes. Two 13-mm side ports permit insertion of a thermometer, delivery of titrant or inert gas and reaction sampling. The angled side ports also simplify transfer of reactants and products. Jacketing of the reaction well allows temperature control of exothermic and enzyme reactions. Stirring is easily achieved with a magnetic stir bar and laboratory stirring unit. These units are completely adaptable to the micro-connectors and accessories of the Reacti-Ware System.
Circle No. 86 on Reader Enquiry Card.



CO_2 Laser attenuators. Rofin announces a new series of CO_2 laser attenuators designed to accommodate a range of input powers from 15 to 500 W. Designated the 7530 series, they are designed to control accurately the power output of any CO_2 laser having linearly polarised output. For unpolarised lasers two attenuators in series can be used to provide a more limited range of attenuation. The range includes both manual and automatic units, the manual units being calibrated at 2° increments. The automatic units are fully computer compatible and may be set to any desired attenuation. For extra safety, the control console may be used remotely from the attenuator.
Circle No. 87 on Reader Enquiry Card.

Affinity absorbents: Immobilised sugars. Pierce. A new line of affinity adsorbents for isolation and purification of lectins, carbohydrate binding proteins, toxins and glycosidases is now available from Pierce. Among the 12 Selectins now offered are immobilised *N*-acetyl-D-glucosamine, lactose, maltose, melibiose, *N*-acetyl-D-galactosamine, D-galactosamine, L-fucose and D-mannose. The Selectins are referenced with preparative applications, binding capacities and ligand-leash structure.
Circle No. 88 on Reader Enquiry Card.

Water bath. Thermolyne announces its new Temptronic 100 water bath, which features selectable temperature set-points, digital readout and stable, uniform bath temperatures. A reset switch allows the operator to dial in a desired temperature to 0.1°C. The Temptronic 100 water bath will heat to the set temperature without further adjustment. It is available in either 120 or 240 V operation and weighs only 14.061 kg. An optional gabled cover is also available. A circulating pump combined with an instant feedback electronic control provides ±0.5°C control to 60°C.
Circle No. 89 on Reader Enquiry Card.

Personnel radiation chirper. Radiation Monitoring Devices. Personnel chirpers are very useful safety instruments but are often not worn because of their bulk and weight. Los Alamos Scientific Laboratories, therefore, have developed a miniature chirper small enough and light enough to be worn on a shirt collar. The device was made possible by the use of a 2 mm^3 chip of CdTe which replaces the much larger Geiger tube sensor. The high sensitivity, reliability and low power requirement (5 V) of the CdTe enabled the new chirper to be quickly accepted by personnel working in nuclear radiation environments.
Circle No. 90 on Reader Enquiry Card.

Microprocessor controlled anaerobic chamber. Lab-Line Instruments has introduced Model 6500 PACE, the microprocessor controlled anaerobic chamber. The microprocessor automatically brings the interchange to anaerobiosis and also controls the locks on the interchange doors to assure opening only in anaerobic conditions. It also continuously monitors all chamber conditions and controls an alarm system. PACE is constructed of steel with a flexible vinyl glove port panel. A radiant warm wall incubator with sliding plexiglas doors is built into the upper right hand side of the chamber to allow the entire 44″ × 26″ floor area free for work space. A digital LED display on the front panel allows visual monitoring of incubator temperature and chamber humidity. Constant circulation of chamber atmosphere through the catalyst and desiccant assures strict anaerobiosis and humidity control.
Circle No. 91 on Reader Enquiry Card.

The Model 6500 PACE

Freeze-dryer. FTS Systems. FTS Dura-Dry freeze-dryers eliminate the effects of constant corrosive attack by using titanium and polypropylene in the critical vapour-contact areas of the system. Further, the Dura-Dry assembly arrangement makes all vital parts of the system accessible for close-up visual examination, removal or substitution. Equipment is housed in a practical, take-apart cabinet that provides a support surface and slip-fit vacuum connection for various manifold arrangements, bulk tray dryers and multiple-shelf *in-vacuo* stoppering units. Options for additional protection include chemical 'up-stream' acid filters; chemically resistant vacuum pumps; manual purge systems; product protection during power failure and sterile air-bleed-back systems. The Dura-Dry has a total freeze-drying capability of 20 l.
Circle No. 92 on Reader Enquiry Card.

The FTS Dura-Dry freeze-dryer

Powermeter. Oriel announce a new addition to their range of photoresist products. The 8427 UV Powermeter is a highly reliable, direct reading and calibrated measurement system. A proprietary technique of system calibration, permits the user to choose from a variety of sensor responses. Each can be plugged into the measurement package and is precalibrated to be direct reading without adjustments of the electronics. Ultra-stable silicon detectors are used with glass absorption filters to shape the spectral response.
Circle No. 93 on Reader Enquiry Card.

Guinea pig complement. Cedarlane Hemo-Lo guinea pig complement is designed specifically for sensitive antibody forming cell plaque assays utilising free or haptenated sheep red blood cells (SRBC) as indicators. This reagent is pre-absorbed with SRBC to reduce background haemolysis. Cedarlane Low-Tox guinea pig complement is a highly potent source of guinea pig complement which has been absorbed with agarose to remove background toxicity to mouse lymphocytes. Each batch is tested for high complement activity and low background toxicity to mouse thymocytes.
Circle No. 94 on Reader Enquiry Card.

APPOINTMENTS VACANT

KING'S COLLEGE HOSPITAL DENTAL SCHOOL
(University of London)
Denmark Hill,
London SE5 8RX

DEPARTMENT OF ORAL PATHOLOGY
HISTOPATHOLOGY

A vacancy has arisen for a Senior Medical Laboratory Scientific Officer or Medical Laboratory Scientific Officer to participate in routine histopathology.

Good facilities exist for becoming acquainted with a wide range of modern morphological techniques and opportunities are available for the successful candidate to participate in research programmes. Salary on scale £4,347 to £5,769 (SMLSO) or £3,261 to £4,680 (MLSO) & £354 London Weighting (under review) according to age, qualifications and experience.

Applications, giving full curriculum vitae and names and addresses of 2 referees should be sent to the Secretary of the Medical School. Further details available from Professor Garrett's Secretary on 01-274 6222 Ext. 2885. 2432(A)

FACULTY POSITION

The Department of Mechanical Engineering at the University of Southern California has openings for faculty positions at all levels with teaching and research interests in fluid dynamics, heat transfer; thermodynamics and combusion; computer aided design, manufacture and control and biomechanics. Applicants must include an up-to-date resume, including a comprehensive list of publications and supply the names of five references who know of their qualifications intimately and who can be contacted for letters of recommendation. Direct inquiries to Dr Tony Maxworthy, Chairman, Dept. of Mech. Engr., Univ. So. Calif., Los Angeles, CA 90007. EOE/M/F/H. W212(A)

THE POLYTECHNIC OF CENTRAL LONDON

School of Engineering and Science
Applied Microbiology and Biochemistry Research Group

POST-DOCTORAL RESEARCH FELLOW IN ENZYME TECHNOLOGY

Salary:— £4,221 to £4,677 inclusive of London Allowance.

Applications are invited from suitably qualified persons for the above 2-year post. Candidates should have interest/experience in applied enzymology, with particular reference to the use of microbial hydrolytic enzymes for the degradation of natural polysaccharides, under enzyme reactor conditions.

Application form and further details from the Establishment Officer, PCL, 309 Regent Street, London W1R 8AL (Tel. 01-580 2020 ext. 212). 2390(A)

LEICESTER POLYTECHNIC

SCHOOL OF LIFE SCIENCES

Applications are invited from appropriately qualified graduates for the post of:

RESEARCH ASSISTANT

The successful applicant will work with Dr R S Oldham in collaboration with Dr Alistair Ferguson of the Anglian Water Authority on water circulation patterns and biological processes in a large reservoir. The appointee will investigate and model the effect of wind and water currents upon the planktonic and benthic communities of Rutland Water. This is applied research with the objective of improving the efficiency of water abstraction. It will be essentially a physically based project, but with a strong biological component.

The successful applicant will be expected to register for a higher degree and will receive an award equivalent to that paid to NERC/SRC research students (currently £1,610 per annum *tax free*). The award will be renewable annually for a 3 year period subject to satisfactory progress.

Application form and further details are available from: Staffing Officer, Leicester Polytechnic, P O Box 143, Leicester LE1 9BH Tel: (0533) 551551 Extension 2303. 2368(A)

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF CLINICAL BIOCHEMISTRY

Vacancies exist for two Research Technicians in the above Department. The posts are funded by Pharmaceutical Companies and are for 1 year in the first instance. Duties include measurement of metabolic intermediates and hypoglycaemic drugs in patient's serum.

Applicants should have HNC, 1st degree or several years laboratory experience and should send curriculum vitae and names and addresses of 2 referees to Professor C. N. Hales, Department of Clinical Biochemistry, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QR, by 25th July. Starting salary up to £2,930. 2442(A)

UNIVERSITY OF NATAL

DEPARTMENT OF PHYSICS
Durban

PLASMA PHYSICIST

Postdoctoral Research Fellowship available October 1979 for at least one year, for experimental research in plasma waves and beam-plasma interactions. Salary range R8,100 to R11,200 p.a., plus travel allowance each way. Recent postdoc or sabbatical visitor suitable.

Send application, resumé and three referees' reports by September 1st quoting reference ADVD38/79 to Prof. M. A. Hellberg, Plasma Physics Research Institute, University of Natal, Durban, South Africa. W200(A)

THE UNIVERSITY OF MANCHESTER

RESEARCH FELLOW IN PHARMACOLOGY

Applications are invited for this postdoctoral post to work in the field of calcium antagonist drugs. The work will initially involve the determination of the mode of action of novel calcium antagonists on cardiovascular and uterine tissues. The post is tenable for one year and may be extended for a further two years. Initial salary p.a. is £4,232 (£4,333 from October 1979). Particulars and application forms (returnable by July 16th) from Dr. A. H. Weston, Department of Pharmacology, Manchester University, Oxford Road, Manchester M13 9PT. 2378(A)

UNIVERSITY OF DURHAM

DEPARTMENT OF BOTANY

Applications are invited from Botanists, Biologists and Biochemists for several posts of Postdoctoral Research Assistant for two years from 1st September, 1979 or later by arrangement.

For one post, plant physiology or histochemical experience is required and for another, knowledge of recombinant DNA technology.

Initial salary £4,232 or £4,505 (£4,333 per annum and £5,622 per annum from 1st October 1979) within Range 1A plus superannuation.

Applications (3 copies) naming three referees should be sent by 27 July 1979 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. 2376(A)

Senior Research Chemist

We have a vacancy for an Organic Chemist to join our Chemistry Research Department. This post, which is under the scientific direction of the Director of Research, provides an opportunity for taking charge of a programme of work on products of potential interest for medicinal use.

Applicants, male or female, must possess a PhD qualification preferably with some post-Doctoral experience in an academic environment or two to three years industrial experience of innovative research in the Pharmaceutical industry. However, newly qualified PhD's or those expecting this qualification will also be considered, particularly if their research interests involve heterocyclic chemistry.

Roche Products Limited is part of an international Swiss-based pharmaceutical company and the terms and conditions of service are those to be expected from a leader in this industry.

If you would like further information about this post and an application form please write to or telephone quoting reference RC27, Mr. J. G. Bennett, Personnel Manager, Roche Products Limited, P.O. Box 8, Welwyn Garden City, Hertfordshire AL7 3AY, Telephone Welwyn Garden 28128. 2409(A)

ROCHE

Senior Virologist

National Biological Standards Laboratory
Viral Products Section
Parkville, Victoria
Commonwealth Department of Health

A vacancy exists for a senior Virologist in the Viral Products Laboratory. This Laboratory is responsible for the control of the quality of the human and veterinary viral vaccines used in Australia. It is located in a suburban area, close to Melbourne. The capital city of Victoria, Melbourne (population 2.5 million) Australia's second largest city, is located on Australia's south east coast and has a temperate climate.

Duties:
Control and direct a team engaged in the evaluation and testing of human viral vaccines, in the development of standards for these vaccines, and in research into problems associated with the safety and efficacy of the vaccines.

Qualifications:
An appropriate degree or diploma in Science or equivalent qualification. Post-graduate qualifications and extensive experience in virology and immunology desirable.

Salary:
Within the range $20,443-21,702 (Australian) (At present exchange rate £1 = $A1.90 approx.).

Conditions include four weeks annual recreation leave, long service leave, cumulative sick leave and superannuation benefits. Overseas appointees may receive assistance with fares, removal expenses, and temporary accommodation costs.

Applications to be submitted to: Director of Health, Commonwealth Government Centre, Cnr Spring and Latrobe Streets, Melbourne, Victoria, Australia 3000.

Enquiries in Britain may be made with the Chief Medical Officer at Canberra House, Maltravers Street, Strand, London WC2R 3EH. Applications close on July 26 1979. 2430(A)

SENIOR PHARMACOLOGIST
St. Albans

WEDDEL PHARMACEUTICALS LTD. are seeking an experienced Pharmacologist to fill a key post as Section Leader in the Biological Services Department at the Union International Research Centre in St. Albans, Herts.

The successful candidate will lead a team engaged in pharmacological research and development of naturally-occurring substances active on the cardiovascular system. Ideally, we are seeking someone with a PhD in Pharmacology or a related subject and it would be advantageous if the candidate has several years' experience of the pharmaceutical industry, perhaps working in cardiovascular or biochemical pharmacology. Applications, which will be treated in confidence, with full curriculum vitae should be made to:

Mr J. E. Dawes (AD 6088),
The Union International Company Ltd.,
14 West Smithfield,
London,
EC1A 9JN

2440(A)

THE POLYTECHNIC OF NORTH LONDON
DEPARTMENT OF GEOGRAPHY
TECHNICIAN GRADE 2B

The post involves supervision of the Departmental Map Library and general assistance in the Laboratories.

The post offers an excellent opportunity to gain a first-hand experience in a large and developing Department which includes over 250 students and 18 full-time academic staff. The work is at degree and post-graduate level.

Education level and experience (inclusive of training period) ONC or OND or 2 'A' levels, or Ordinary City & Guilds or equivalent. Three years' experience.

Salary Scale: £3282 to £3663 inclusive of London Weighting.

Application form can be obtained from the Establishment Officer, The Polytechnic of North London, Holloway Road, N7 8DB. 2388(A)

POSTDOCTORAL POSITION

Postdoctoral position available for a biochemist or chemist on isolation and characterization of components and receptors from blood platelet membranes. Regular salary of the Weizmann Institute for this grade. Available from August 1, 1979. Write to: Dr Avner Rotman, Department of Membrane Research, The Weizmann Institute of Science, Rehovot, Israel. W206(A)

UNIVERSITY OF SUSSEX
School of Biological Sciences
LABORATORY OF EXPERIMENTAL PSYCHOLOGY
Lectureship in Psychology

Applications are invited from candidates in Human Experimental Psychology, with an interest in memory, attention and performance. Special consideration will be given to those capable of teaching statistics.

Salary scale: £4,333 to £8,992 (under review)

Further information may be obtained from Professor N. J. Macintosh, Laboratory of Experimental Psychology, University of Sussex, Falmer, Brighton BN1 9QG.

Candidates should apply to: Secretary of Science, Science Office (E), University of Sussex, Falmer, Brighton BN1 9RH.

Closing date for applications 27 July 1979. 2434(A)

UNIVERSITY OF WARWICK
RESEARCH TECHNICIANS

The Department of Biological Sciences has vacancies in its four Research Groups, namely Chloroplast development, Developmental Biology (Molecular Genetics), Microbiology and Virology. The posts involve working under the direction of a senior scientist on a specific research project using the modern experimental techniques and instrumentation of molecular biology. The posts are for contract periods of one to three years and are available from October, 1979. Applications are invited from graduates and others with appropriate qualifications in biochemistry and/or microbiology. Salary either on Technician Grade 2B scale £2,759 to £3,138 p.a., or Grade 3 scale £2,931 to £3,336 p.a. Applications by letter giving full details of qualifications, experience etc to the Personnel Office, University of Warwick, Coventry CV4 7AL, quoting Ref. No: 47/D/79 by 20th July, 1979. 2396(A)

UNIVERSITY OF LEICESTER
DEPARTMENT OF ZOOLOGY
RESEARCH TECHNICIAN

Applications are invited for the post of Research Technician Grade 5 to work with a group of investigators who are studying various aspects of the structure and function of chromosomes in amphibians and other animals. Preference will be given to applicants who have some experience of technologies associated with biochemistry of nucleic acids or those involved in advanced light and electron microscopy. The appointment will be for 3 years, in the first instance, commencing 1st September 1979. Salary will be on the range £3,474 to £4,056. Applications, together with the names of 2 referees, should be sent to Professor H. C. Macgregor, Zoology Department, University of Leicester, Leicester LE1 7RH, before 14th July 1979. 2404(A)

INSTITUTE OF CANCER RESEARCH: Junior Technician required for the Department of Molecular Biology, Chester Beatty Research Institute, Fulham Road, London, SW3, in the general field of protein chemistry. The successful candidate will assist in the isolation and characterisation of proteins and peptides. Applicants should have at least 2 'A' levels in Maths., Physics or Chemistry. Salary in scale £2,370 to £3,015 p.a. plus London Allowance of £354 p.a. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/76. 2373(A)

ORGANIC/ PHYSICAL CHEMIST

We have a vacancy for an organic or physical chemist for multidisciplinary work on organic electro-optical display materials and their applications.

Applicants should possess a good degree and/or membership of the Royal Institute of Chemistry and should have experience in Research and Development, including knowledge of physical and electronic measurement techniques. Experience in the field of display devices would be an added advantage.

This position offers interesting work, with an opportunity to contribute to the expanding technology of electro-optical devices.

We offer all the normal benefits associated with a major progressive company, including a competitive salary, a 37 hour week, contributory pension scheme, hospital fund and a discount on certain GEC products. Relocation expenses will be paid where appropriate.

Please write to: Mrs. S. A. Fox, Marconi Research Laboratories, West Hanningfield Road, Great Baddow, Chelmsford, Essex, CM2 8HN.

The above vacancy is open to both men and women.

Marconi Research Laboratories

GEC-Marconi Electronics Ltd.

2425(A)

UNIVERSITY OF ESSEX

FELLOW in the DEPARTMENT OF PHYSICS

(Laser-Photoconductivity in Semiconductors)

Applications are invited for a post of Fellow (starting salary up to £4,776 on Range IA) tenable for 3 years, to carry out SRC — funded experimental research into deep-level impurities in semiconductors in collaboration with Dr B. K. Ridley. Candidates should have a PhD or equivalent qualification. Experience of infrared lasers, semiconductors and low-temperature techniques would be useful but not essential. The appointment will run from 1 September 1979 or as soon as possible thereafter.

Application should be made before 16 July 1979 to Mrs D. A. Weatherall, Department of Physics, University of Essex, Wivenhoe Park, Colchester CO4 3SQ (Tel. 0206 862286).

2436(A)

ASSISTANT PROFESSORS

Applications are invited for two positions at the level of Assistant Professor in the Department of Pharmacology of Yale University School of Medicine. Applicants must have a doctoral degree and postdoctoral experience. Preference will be given to individuals with experience and research skills in the neural sciences, particularly at the molecular and cellular levels. Demonstrated potential to initiate a strong independent research program and to engage in the teaching activities of the department are expected. Interested candidates should send curriculum vitae, reprints, a brief description of research interests and the names of three possible references by August 15, 1979 to: Dr. Alan C. Sartorelli, Chairman, Department of Pharmacology, Yale University School of Medicine, New Haven, Connecticut 06510. An Affirmative Action/Equal Opportunity Employer. W211(A)

UNIVERSITY OF ABERDEEN

TECHNICIAN

Required to look after the electron-microscope unit in the Department of Botany and to undertake a range of work associated with transmission and scanning electron microscopes. Applicants should hold an ONC (or equivalent qualification), have had at least 4 years' laboratory experience and have an interest in electronics and photography; training will be given in electron microscopy.

For suitably qualified candidate, salary on scale £2,931 to £3,336. Applications from recent graduates interested in training in electron microscopy will be considered for appointment against this post; salary for such a candidate during initial training period would be on scale £2,556 to £2,724.

Applications giving date of birth, educational qualifications and previous experience should reach the Secretary, University Office, Regent Walk, Aberdeen AB9 1FX, by 27 July, and quote Ref. No. 142/79. 2398(A)

UNIVERSITY OF LEEDS. Departments of Biochemistry and Genetics. Applications are invited for a Research Technician, Grade 5, to assist with projects based on an inter-departmental protei sequencing unit. The appointment, financed by a grant from the Science Research Council to Dr. J. B. C. Findlay (Biochemistry) and Dr. J. C. Wootton (Genetics). The work will include operation of an amino acid analyser with computer integration and of a solid phase sequencer. Applicants should have a Degree, an HNC or equivalent, or proven experience and expertise in this field. Experience in biochemical methods, instrumentation and in the processing of quantitative data would be an advantage. Salary on the scale £3,474 to £4,056 pa (under review). Applications in writing, stating date of birth, qualifications and career details, and the names of 2 referees to Dr. J. B. C. Findlay, Department of Biochemistry, 9 Hyde Terrace, Leeds LS2 9LS. 2428(A)

JOHN INNES INSTITUTE

DEPARTMENT OF APPLIED GENETICS

THREE YEAR FELLOWSHIP FUNDED BY THE JOHN INNES CHARITY

Applications are invited from molecular biologists/geneticists to study the basis and manipulation of cytoplasmic male sterility in sugar beet. Further particulars may be obtained from Professor D. Roy Davies.

Appointment will be as Higher Scientific Officer (£4,101 to £5,448) (pay increase pending), starting salary depending on qualifications and experience. Non-contributory superannuation. Minimum qualifications: First or Upper second class degree in molecular biology, genetics or virology with at least two years' relevant experience. Preference will be given to candidates with a PhD.

Applications, quoting reference AG/42, giving full particulars and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH, not later than 30th July, 1979. 2393(E)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING

LECTURER/ASSISTANT RADIATION PROTECTION OFFICER

Applications are invited from suitably qualified Physicists or Radio Chemists for the post of Lecturer in the Department of Bio-Medical Physics and Bio-Engineering. The person will also act as Assistant to the Radiation Protection Officer who has the responsibility for radiation protection in the University, and the Hospitals of the Grampian, Orkney and Shetland Health Boards.

Salary on scale £4,232 to £8,452 per annum (under review), with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (two copies) should be lodged by 27 July 1979. 2391(A)

ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS AL5 2JQ

BIOLOGIST

to join a small group working on the taxonomy of root-knot nematodes. The person appointed will be expected to take a major role in initiating and developing the work. Previous experience in nematology and/or an interest in taxonomy preferred. The position is funded by the Overseas Development Ministry and the appointment will be for three years only.

Qualifications: First or Upper Second Class Honours Degree in a biological subject. Preference given to candidates with a PhD degree.

Appointment in grade of Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448). (Pay award pending). At least two years' relevant post-graduate experience is required for appointment as HSO. Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 402 by 8th August, 1979. Further details on request. 2443(A)

UNIVERSITY OF LIVERPOOL

TECHNICIAN (GRADE 5)

DEPARTMENT OF BIOCHEMISTRY

For the Electron Microscope unit to carry out work in association with several research groups.

Applicants should possess HNC or equivalent as minimum qualification and minimum of ten years appropriate experience. Salary range £3,474 to £4,056 p.a. Application forms may be obtained from the Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/683. 2418(A)

Analytical Research in Drug Development

We have a number of vacancies for male and female scientists and technicians to work on various aspects of drug analyses.

Analytical Development

We seek a scientist able to work with minimal supervision on the development of methods for the analysis of new drugs in biological fluids. The ideal candidate will hold a PhD in a relevant science (chemistry, analytical chemistry, biochemistry) with 2-3 years experience in drug research.

Mass Spectrometry

This vacancy is for an experienced technician (HNC or degree) to assist in the operation and maintenance of our MS 30 mass spectrometer (with GC and data system). The work of this unit is varied including characterisation of newly synthesised compounds, identification of drug metabolites isolated from biological samples, and the use of the GC-MS system for quantitative drug analysis. Although we are looking for experience, training would be given to a candidate with suitable qualities.

Technicians

We also have vacancies at various levels of seniority (A levels to HNC) for technical staff to assist in the work of the department. As indicated above this involves the development of methods for the analysis of drugs (both new and marketed) in biological fluids using chromatography and spectrophotometry, and the application of such methods to interesting areas of drug research (pharmacokinetics, clinical trials, toxicology, etc). Applications are invited from technicians with an interest in drug research or analysis as a career and training will be given to suitable candidates.

Conditions include four weeks holiday, flexible working hours, subsidised staff restaurant, free private health scheme and excellent sports and social facilities including an open air heated swimming pool.

Please write or telephone for an application form to:
Adrian Forrest, Personnel Department, Hoechst UK Limited, Walton Manor, Walton, Milton Keynes, Bucks.
Tel: Pineham 5068

Hoechst

2412(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH FELLOWS IN MOLECULAR GENETICS — GENETICS DEPARTMENT
(two posts)

Applicants should preferably have experience in the areas of microbial or plasmid genetics and recombinant DNA techniques. The successful candidates will be strongly encouraged to collaborate in joint projects with existing groups in the Genetics Department. These include: Professor J. A. Pateman, with broad interests in the carbon and nitrogen regulation of gene expression in simple eucaryotes and particular emphasis on the glutamate dehydrogenases, glutamine synthetase and amino acid catabolism; Dr. G. D. Clark-Walker, working on mitochondrial and plasmid genetics in yeast; Dr. B. Rolfe and Dr. J. Shine, working on nitrogen fixation genes in Rhizobia and the structure and expression of eucaryote genes.

Applications should be lodged as soon as possible.

FACULTY OF SCIENCE
DEPARTMENT OF MICROBIOLOGY

SENIOR TUTOR IN MICROBIOLOGY

Applicants should have a higher degree in microbiology with experience in medical microbiology. The department is developing teaching in areas of microbial pathogenesis and immunology, and applicants able to contribute to course development and teaching in microbial pathogenesis in particular will be preferred.

The successful applicant will be required to assist in preparations, supervision and assessment of practical classes in second year general microbiology, to participate in training PhD and Honours students, and to contribute to the departmental research programme.

Closing date: 27 July, 1979.

Salary will be in accordance with qualifications and experience within the range: Research Fellow $A15,786 to $20,606; Senior Tutor $A13,606 to $15,586 per annum. Present exchange rates: $A1 = UK53p; $US1.10.

Terms of Appointment: Research Fellow — three years in the first instance with the possibility of extension to five years; Senior Tutor — one year in the first instance with the possibility of yearly renewal up to five years.

Other Conditions: Reasonable appointment expenses are paid. Travel expenses are paid for Senior Tutors appointed from Australia and New Zealand only. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should first obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H0PF. 2438(A)

British Museum (Natural History)

The British Museum (Natural History) is an institution for taxonomic research and an education focal point for the public. The main aim of the research is to produce definitive accounts of the world's animals, plants and minerals as well as the preservation of an extensive collection of fossils. There are unrivalled opportunities for research, aided by comprehensive library and technical services.

HEAD OF FRESHWATER ALGAE SECTION

. . . to supervise the work of junior staff, conduct research on the taxonomy of freshwater Chlorophyta and/or Rhodophyta and organise the SEction's curatorial and advisory service.

Candidates, normally aged under 32, should have a good honours degree or equivalent in an appropriate discipline and at least 2 years' postgraduate experience. Experience in algal taxonomy is highly desirable. Appointment as Senior Scientific Officer or Higher Scientific Officer. *Ref: SB/55/DK*

PALAEONTOLOGISTS

. . . to work on either Fossil Bryozoa or Palaeozoic Plants and take responsibility for the curation and conservation of the appropriate collection. The work will also involve dealing with scientific and general enquiries, and developing and maintaining relationships with scientists and research institutions throughout the world. The successful candidates will each undertake approved research in the appropriate field which in Fossil Bryozoa is expected to centre on palaeozoic forms and in Palaeozoic Plants will be on aspects of the gross morphology of plants, not palynology.

Applicants must have a good honours degree in Geology or Botany, and at least 2 years' relevant postgraduate experience. A strong interest in fossil bryozoa or plant taxonomy and gross morphology, and a knowledge of modern curatorial methods would be an advantage. Appointment as Senior Scientific Officer or Higher Scientific Officer. *Ref: SB/56/DK.*

ENTOMOLOGISTS

Taxonomic Research on Caraboidea/ Scarabaeoidea.

The successful candidate will work in the section dealing with Caraboidea, Scarabaeoidea and Staphylinoidea and will undertake taxonomic research on either Caraboidea or Scarabaeoidea, including their immature stages. The work will include curatorial duties aimed at the improvement of the National Insect Collection through exchange, collecting and rearing. Departmental staff are encouraged not only to collect in the field themselves, but also to take part in expeditions abroad.

Medical Insect Studies

The successful candidate will supervise and participate in taxonomic research on one or more families of medically important Diptera and become a specialist adviser on mosquitoes. The work will also involve improving and maintaining the national collection of medical insects.

Candidates, normally aged under 32, should have a good honours degree or equivalent in zoology, preferably with entomology. At least 2 years' relevant postgraduate experience is essential. Appointment as Senior Scientific Officer or Higher Scientific Officer.

Taxonomic Research on Coccoidea

The successful candidate will participate in taxonomic research studies on scale insects and mealy bugs, and maintain and improve the Department's collection through exchanges with other specialists and by collecting and rearing. The work will involve a great deal of microscope slide preparation, and some supervision of junior staff. In addition, the entomologist will deal with enquiries from other institutions and members of the public.

Candidates, normally aged under 30, should have a good honours degree or equivalent in zoology, preferably with entomology. Relevant postgraduate experience is advantageous; at least 2 years is essential for Higher Scientific Officer level. Appointment as Higher Scientific Officer or Scientific Officer. *Ref: SB/54/DK*

Salary for Senior Scientific Officer in the range £5675-£7420; Higher Scientific Officer £4620-£5970; and Scientific Officer £3360-£4910. Level of appointment dependant on qualifications and experience.

All salaries are under review. Promotion prospects. Non-contributory pension scheme.

These posts are exempted from the Government's ban on recruitment.

For further information and an application form (to be returned by 27 July 1979), write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote appropriate reference.*

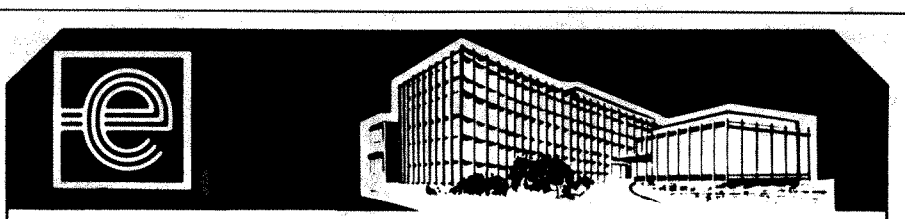
INTERNATIONAL LABORATORY FOR RESEARCH ON ANIMAL DISEASES (ILRAD)
Nairobi, Kenya

IMMUNOLOGIST TO WORK ON PARASITIC DISEASES



There are in the laboratory of the Director of ILRAD two vacancies for immunologists to work on theileriosis. The research will include the infection and transformation of bovine lymphocytes and other cell types by theileria parasites and analysis of cell-mediated immune responses to the parasites and parasitized cells.

Applicants should have experience of cellular immunology and of parasitic or other infectious diseases.

Salary will depend on age and experience. Perquisites include moving allowance, housing and commutation allowances, medical and retirement benefits.

Applications, with *curriculum vitae*, list of publications and the names of three referees, should be submitted to the Director, ILRAD, PO Box 30709, Nairobi, Kenya by 12th August 1979.

W203(A)

RESEARCH OFFICER

CHEMISTRY DIVISION – CORROSION RESEARCH

A scientist with PhD or good honours degree and relevant experience is required for research on corrosion problems in power plant. The successful applicant will work with other scientists concerned with a wide range of corrosion problems involving ferrous and non-ferrous metals in aqueous and high temperature environments. He or she will be expected to contribute to fundamental understanding of corrosion mechanisms and to advise on corrosion problems in plant. Excellent facilities are available for corrosion measurements and the examination of corroded specimens.

According to age, experience and qualifications the appointment will be made within incremental salary ranges rising to £6035 or £7050 plus a payment under a Self Financing Productivity Scheme ranging between £8 and £17 per month.

The Laboratories are situated in a pleasant part of Surrey and offer attractive conditions of service, and facilities for the total of 800 Research and Support Staff engaged in a broad spectrum of research into the materials, technologies, and plant performance problems of the Central Electricity Generating Board.

Application forms are available from the Head of Personnel Development & Services Section, Central Electricity Research Laboratories, Kelvin Avenue, Leatherhead, Surrey KT22 7SE or telephone Leatherhead 74488 Ext 363, quoting reference number **RL/39/NS.** Closing date is: **Friday 20 July 1979.** 2457(A)

CENTRAL ELECTRICITY RESEARCH LABORATORIES

INSTITUTE OF CANCER RESEARCH: Applications invited for appointment as a TECHNICIAN in the Physics Department, Royal Marsden Hospital, Sutton, Surrey. Work includes the dosimetry and planning of radiation treatments, with linear accelerators and other equipment, and involves the use of a digital computer system. Previous experience not required. For applicants with a degree in Physics or allied science, appointment on scale £3,261 to £4,680 p.a. (under review) plus London Allowance of £354 p.a., starting salary depending on age and experience. Applications in duplicate (within two weeks of advertisement) giving full details of education and qualifications and with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/77. For further details telephone Dr. N. G. Trott, 01-642 6011, Ext. 250. 2379(A)

A RESEARCH ASSISTANT as a staff member is required by the Faculty of Medicine of Memorial University of Newfoundland. The incumbent must have academic training at the masters level or equivalent with experience to enable him to participate in research on human physiological circadian rhythms. The incumbent will be responsible for the modification of research procedures and computer analyses. There will be some field work. This is an established post and carries a commencing salary of $13,292. Applications or enquiries should be directed to Dr. Mary Lobban, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, A1B 3V6. W201(A)

BREWING RESEARCH FOUNDATION
NUTFIELD, SURREY

A biochemist or microbial physiologist is required to study the regulation of the enzymic synthesis of ethyl acetate by Saccharomyces cerevisiae.

Experience of lipid metabolism and with membrane bound enzymes would be helpful. The post seems likely to suit a graduate with several years' relevant experience but would possibly be suitable for a new graduate with in-course experience on the appropriate topics.

The appointment will be made on either the scientist (£4979-£6882) or experimental officer (£4486-£6198) scales, in the Microbiology Section.

Applications, including curriculum vitae and names of two referees should be sent to:—

Assistant Director, Brewing Research Foundation, Lyttel Hall, Nutfield, REDHILL, Surrey, RH1 4HY.

MEDICAL RESEARCH COUNCIL VIROLOGY UNIT

ENZYMOLOGIST PROTEIN BIOCHEMIST and NUCLEIC ACID BIOCHEMIST

wo vacancies exist for postdoctoral search scientists with experience in nzymology/protein biochemistry or ucleic acid biochemistry to work on a riety of molecular biological problems volving Herpes Simplex Virus and other ammalian virus systems.

Previous experience with virus systems is lvantageous but not essential.

The appointment will be for three years. lary on an appropriate point on Grade 2 the non-clinical scientific staff scale. pplicants should send a Curriculum vitae ving full details of qualifications and perience and the names and addresses of ree professional referees to: Professor J. . Subak-Sharpe, Institute of Virology, niversity of Glasgow, Church Street, LASGOW, G11 5JR, by 1st August, '79. 2454(A)

PROFESSOR OF ASTRONOMY University of Victoria Victoria B.C. Canada

he Department of Physics at the niversity of Victoria anticipates the tablishment of an endowed position for a stinguished astronomer at the Full ofessor rank to begin on or after July 1, '80. Candidates should possess an tensive research record and have an ternational reputation. They should be lling to interact with faculty, research rsonnel and students at the University d with others in the community of tronomers in Victoria. Preference will be en to an observational astronomer with oretical interests. In addition to the ailability of research facilities at the iversity and at the nearby Dominion trophysical Observatory, opportunities ll exist for observing time on the 3.6m nada-France-Hawaii telescope which is w nearing completion in Hawaii.

Expressions of interest, enquiries and plications are invited. Please reply to: airman, Department of Physics, iversity of Victoria, Victoria, B.C. V8W 2, Canada.

The closing date for receipt of plications is January 1, 1980.

W204(A)

Experimental Support Staff

Neutron Scattering Instrumentation

A new intense source of pulsed neutron beams, the spallation neutron source, is being built at the Rutherford Laboratory for use in research programmes of UK universities and polytechnics. A substantial number of neutron scattering instruments will be provided based on the time-of-flight method and outline designs have already been completed for the first seven. A wide range of equipment and techniques is involved; for example, position sensitive detectors for epithermal neutrons; high resolution choppers; sample environments controlling parameters such as temperature, pressure, magnetic field; neutron guides; neutron polarisation systems.

There are vacancies for support staff to participate in the development and provision of this equipment in the Neutron Beam Research Programme, which is expanding to meet the requirements for efficient utilisation of the SNS. When fully operational, in the 1980's, the SNS will be a world class facility serving a very widely based scientific community. As part of their development activities those appointed will have opportunities to work with research scientists using instruments at Harwell and the Institut Laue-Langevin, Grenoble. In addition, close collaboration is maintained with laboratories in the USA and elsewhere where spallation sources are being built. Applications should have HNC or HND and relevant experience or degree in physics or applied physics. Some experience in fields such as electronics, high vacuum, or cryogenics would be an advantage. Appointments will be made to permanent positions in the Science Group at the level of Scientific Officer or Higher Scientific Officer. Salary scales (at present under review).

Scientific Officer £3,037-£4,724.
Higher Scientific Officer £4,388-£5,820.
Please apply to
Jane Griffiths in the Personnel Group on Abingdon (0235) 21900 Ext. 510 or write to her quoting Reference No. VN. 818.
Closing date for applications, July 20th 1979.

CHEMICAL NEWS and CURRENT AWARENESS MAGAZINE requires ASSISTANT EDITOR

to edit contributed scientific and professional articles and to write original material. Some experience of magazine editorial work desirable and acquaintance with Chemistry would be helpful. Please write giving full details to the Personnel Officer, The Chemical Society, 30, Russell Square, London WC1B 5DT. 2399(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF METALLURGY AND SCIENCE OF MATERIALS

Two research appointments to study interfacial segregation and precipitation reactions during liquid-phase sintering and subsequent heat-treatment of tungsten-based alloys are available from 1st October, 1979.

The posts may be filled at either postdoctoral level (for 2 years) or predoctoral level (for 3 years) and applications are invited from suitably qualified candidates who have recently completed their D.Phil. or who wish to register for a D.Phil. at the university.

Applications, including a curriculum vitae, and the names and addresses of two referees, should reach the Administrator, Department of Metallurgy and Science of Materials, University of Oxford, Parks Road, Oxford OX1 3PH, not later than the 23rd July, 1979. 2451(A)

Pharmacologist
Gastroenterology

Smith Kline & French Laboratories Limited is the UK subsidiary of the international SmithKline Corporation whose interests include the research and manufacture of pharmaceuticals.

The Research Institute presently operates in Welwyn Garden City, but over the next few years it will be relocating a few miles away to newly-built laboratories in a rural setting.

An opportunity has arisen in our Pharmacology Department for a Graduate Pharmacologist/Physiologist with experience in the field of gastroenterology. This position involves heading a small group conducting basic research into the Gastrointestinal function.

It is envisaged that the successful man or woman will have recently obtained a PhD in a relevant area of research. Experience in the electrophysiology of the gastrointestinal tract would be advantageous. Benefits include free life assurance, discretionary annual bonus, four weeks annual holiday, subsidised cafeteria and a growing Sports and Social Club. Assistance with relocation is available where necessary.

To apply please telephone or write for an Application Form quoting Reference Number NAT 142 to:

Kate Viscardi, Recruitment Administration Officer,

SMITH KLINE &FRENCH LABORATORIES LIMITED

Mundells, Welwyn Garden City, Hertfordshire, AL7 1EY. Telephone: Welwyn Garden 25111, Extension 26.

The Director's research programme is primarily concerned with an evaluation of the advantages which accrue from the use in research of specific pathogen free animals, in particular the cat. A person in the Research Officer category is required to assist the Director in this programme. Opportunities will occur for collaborative work with other departments in the Centre, which cover the whole spectrum of Laboratory animal science.
The successful applicant will have a degree or equivalent in a biological science, and at least two years relevant research experience. Salary will be related to age, qualification and experience and is supplemented by £354 London Weighting. Contributory pension scheme.
Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to The Director, MRC Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF.

MRC Medical Research Council

2417(A)

BIOCHEMISTS — SWEDEN

Pharmacia Fine Chemicals AB manufacturers of Sephadex[R] and other products for biochemical separations require two biochemists to work at our head office in Uppsala, Sweden.
The successful applicant for the first post will join the Scientific Services group of our Export Department, which is responsible for communicating technical information to research workers using chromatography electrophoresis and other biochemical separation methods. This work includes:
- Developing, organising and taking part in courses and symposia
- Scientific information
- Planning and participation in exhibitions

Applicants for this post should have research experience in biochemistry, cell biology or a closely related field and should be prepared to travel for approximately three months per year, throughout the world.

The second successful applicant will join our Scientific and Technical Services group responsible for chromatographic separation methods. The group's activities include:
- The preparation of all kinds of scientific information material
- Work with new products
- Lecturing

but applicants should be prepared for extremely varied work in close co-operation with our research departments and a certain amount of travelling, chiefly within Europe.
Applicants for this position should have research experience in biochemistry or a closely related area.
For both of these positions a good knowledge of a major European language is advantageous but clear and accurate expression in the written word with English as the mother tongue, is essential.
These are responsible positions and carry appropriate salaries. Preferred age is between 25 and 30.
Write in confidence to:

**Mr. David S. Sweetman
Pharmacia (GB) Limited,
Prince Regent Road,
Hounslow, Middlesex
TW3 1NE, England.
Or telephone, during office hours, (01) 572 7321.**

Pharmacia

2416(A)

UNIVERSITY OF REGINA
(Canada)

ASSISTANT PROFESSOR
DEVELOPMENTAL
BIOLOGY

Applications are invited from candidates who have training and experience in the biology of development at the molecular, cellular and organismic level. Expertise in plant development and regeneration from somatic cells is desirable, but not essential. Applicants must have at least two years of postdoctoral experience.
The appointee will share in the teaching of undergraduate and graduate students and is expected to develop an active research programme. Minimum salary: $18,829. Starting date: as soon as possible.
Applications including a curriculum vitae, list of publications, a statement of research interests, and the names of at least three referees should be sent to Dr. H. Bertrand, Department of Biology, University of Regina, Regina, Saskatchewan S4S 0A2, Canada before August 20, 1979. W207A

THE UNIVERSITY
OF SHEFFIELD

Postgraduate School of Librarianship and Information Science

LECTURESHIP IN
INFORMATION SCIENCE

Applications are invited from men a women for the above post. Candidat should have a good honours degree science or technology and a qualification substantial experience in informatic science; they should also present eviden of experience in research. Teaching duti will involve various aspects of compute based bibliographic information system computer programming, and statistic methods as applied to library ar information work. The School has wi research interests among which a research in computer-based informatic retrieval systems, including those involvi chemical structure information. Initi salary in the range £4,333 to £5,199 a ye on scale rising to £8,992 a year. Particula from the Registrar and Secretary, t University, Sheffield S10 2TN to who applications (5 copies) should be sent by August 1979. Quote ref: R334/G.

Geophysics Research

We are looking for graduate scientists, preferably with a Ph.D., to join our Geophysics Research Branch. This is an important opportunity to join in leading research and specialised service work in all aspects of seismic prospecting except instrument development.

Applicants will have a strong mathematics background and be skilled computer users. We need people who study problems from the viewpoint of an earth scientist rather than that of a mathematician. You will be experienced in using large quantities of experimental results to validate hypothetical models and experience related to seismic prospecting will be an advantage.

Our current salary levels, together with a non-contributory pension scheme, subsidised lunches and excellent sports and social facilities now represent outstanding conditions of employment.

Please write giving brief details of age, qualifications and experience quoting reference U.670, to:

Sue Tickle,
Central Recruitment,
The British Petroleum Company Limited,
Britannic House,
Moor Lane,
London EC2Y 9BU.

Process Technology

Antibiotic Fermentation

Merseyside

Dista Products — a leading company in the antibiotics field and a subsidiary of The Eli Lilly International Corporation — invites applications from candidates — for 2 new appointments:

Fermentation Technologist

Where the main objective will be to advise on methods of maintaining and improving productivity and yields through the application of biological expertise in the optimisation of critical process parameters for various fermentation processes.

Candidates for this appointment will have as a minimum a good Honours Degree in one of the Biological Sciences together with specialised knowledge of fermentation processes gained in either an academic or industrial environment. Experience in the use of computer process control techniques would be an advantage.

Process Technologist/ Biochemical Engineer

The main objective will be to increase operating efficiency through the modification and development of new and existing process plant. Candidates will have as a minimum a good Honours Degree in Chemical Engineering with additional experience in: Biochemical Engineering, the recovery of active compounds from fermentation processes together with the application of modern process control techniques.

An excellent salary — commensurate with level of experience is offered for both these challenging opportunities together with BUPA, non-contributory pension scheme and relocation expenses.

PER Professional & Executive Recruitment

If you are interested in these appointments telephone Howell Williams on 051-227 4111 Ext 551 or write to PER, 3rd Floor, Graeme House, Derby Square, Liverpool L2 7SP.

Applications are welcome from both men and women

2408(A)

ROTHAMSTED EXPERIMENTAL STATION

Harpenden, Herts. AL5 2JQ

DATA BANK OFFICER

to assemble and maintain an automated bank of data recorded by field and laboratory staff of the Soil Survey of England and Wales, and to be responsible for computing resources assigned to the Survey.

Qualifications: Degree in a science discipline or HNC with computer programming experience for appointment as SO. Degree or HNC with at least 5 years' computer programming experience for HSO.

Appointment in grade of Scientific Officer £2,839-£4,415, or Higher Scientific Officer £4,101-£5,448. (Pay Award pending). Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 401 by 27th July. Further particulars on request. 2450(A)

UMIST

PAPER SCIENCE SECTION

Prof. H. W. Kropholler

Post-Graduate Research

The Paper Science Section undertakes a variety of research into physical chemical and technological aspects of paper and its manufacture. Current topics include the use of automatic image analysis for studying cellulose fibres, drying and pressing studies, microprocessor applications, pigment coating, waste paper recycling, hemicellulose chemistry and environmental studies.

A variety of grants, up to £3,000 p.a., are available for suitably qualified graduates, and the work can be submitted for a higher degree. Please write for further information and application form to Dr J. C. Roberts, Paper Science Building, UMIST, P.O. Box 88, Manchester M60 1QD. 2447(A)

STUDENTSHIPS and FELLOWSHIPS

UNIVERSITY OF BRISTOL

DEPARTMENT OF CLINICAL BACTERIOLOGY

RESEARCH STUDENTSHIP

Applications are invited from graduates with a first or upper second class honours degree in a biological science for a research studentship sponsored by Janssen Pharmaceutical Ltd, tenable from 1st October 1979. The investigation is concerned with the development of methods for the differentiation of strains of the pathogenic fungus *Candida albicans* and their application to different epidemiological problems, and will be carried out under the supervision of Dr D. W. Warnock. The successful applicant will be expected to register for a PhD degree.

Applications, together with the names of two referees, should be sent as soon as possible to Professor D. C. E. Speller, Bristol Royal Infirmary, Bristol BS2 8HW, from whom further information may be obtained. 2402F

UNIVERSITY OF KENT AT CANTERBURY

BIOLOGICAL LABORATORY

PROTOZOOLOGY RESEARCH STUDENTSHIPS

Applications are invited from candidates holding a good Honours degree in Biochemistry or a related subject for the following research studentships:

(1) an SRC CASE Studentship in collaboration with Pfizer Inc., Sandwich, Kent and jointly supervised by Drs. R. B. Freedman and W. E. Gutteridge to work on ribosome structure and function in *Trichomonas vaginalis*;

(2) a University Studentship, supervised by Dr. W. E. Gutteridge, to work on ribonucleotide reductase in *Trypanosoma cruzi*.

Applications should be submitted to the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH by 16 July 1979. Please quote Ref: PG20/79. 2387(F)

LIVERPOOL POLYTECHNIC
DEPARTMENT OF CHEMISTRY AND BIOCHEMISTRY

The following research posts are available in the Department for suitably qualified candidates to undertake research work towards a PhD degree in October, 1979.

SRC RESEARCH STUDENTSHIP
Five positions are available.
Candidates should have or expect to obtain a First or Upper Second Class Honours degree, or equivalent, in a relevant discipline.
SRC salary rates apply. For CASE awards the collaborating body can also provide up to £735 per annum without reduction in the SRC contribution.

Penetration of Soluble Herbicides into Plants
Drs. R. J. Hamilton and P. A. Sewell (Liverpool Polytechnic) and Dr. T. Merrall (Shell Limited).
CASE Award with Shell Research Limited, Sittingbourne, Kent. The work will involve cultivation of plants, studies of their surface constituents and the development of an assay for water soluble herbicides.
Informal enquiries can be made to Drs. R. J. Hamilton or P. A. Sewell, Tel. 050-207 3581, Extension 31/146.

Insect Attractants and Repellants
Drs. R. J. Hamilton (Liverpool Polytechnic) and Dr. E. A. Bernays (London)
CASE Award with the London Centre for Overseas Post Research. To study the constituents in the *Sorghum* species which attract and repel stem-boring insects. The work will include extraction of plant chemicals, their fractionation using TL, GC, and HPL chromatography, and their identification by ir, nmr, and ms. An interest in developing bioassays with insects is needed.
Technical enquiries should be made to Dr. R. J. Hamilton. Tel: 051-207 3581, Extension 31.

Bacterial Degradation of Steroids
Dr. R. F. Bilton (Liverpool Polytechnic) and Dr. A. Atkinson (Porton Down).
CASE Award with CAMR (PHLS) Porton Down (formerly MRE).
The project will involve a study of the enzymology and genetics involved in the degradation of steroids by bacteria.
Informal enquiries can be made to Dr. R. F. Bilton, Tel: 051-207 3581, Extension 26, or Dr. A. Atkinson (Porton), Tel. 0980-610291.

Studies of Potential Polyhalogenoaromatic Pesticides
Dr. C. A. Heaton. The project will consist of a study of the chemistry and biological (ie pesticidal activity) or polyhalogenodinitrobenzenes and related compounds.
Informal enquiries to Dr. C. A. Heaton, Tel. 051-207 3581, Extension 117.

Glow Discharge Electrolysis (gde)
Drs. P. A. Owens and A. Wood.
In gde an electric discharge is struck, under reduced pressure, between an electrode and the surface of a solution. Charged particles formed in the discharge initiate reactions analogous to those found in radiolysis. The study will involve the elucidation of the mechanism and kinetics of the process. The project will embrace vacuum techniques, electronics and a wide range of analytical methods.
Further information may be obtained from Drs Owen and Wood, Tel. 051-207 3581, Extensions 28/31.

LOCAL EDUCATION AUTHORITY RESEARCH ASSISTANTSHIPS
Two posts are available. Candidates should have or expect to obtain a good Honours degree or its equivalent in Chemistry, Biochemistry or Biology.
Salary: £2,823 to £3,009 per annum.

Metal Oxide Chemistry
(Drs J. Fenerty and J. Pearce)
This project entails the preparation and characterisation of novel metal oxide-hydroxide systems of catalytic importance. Thermal methods of analysis (DTA, TGA) and X-ray powder diffraction will be used extensively in the investigation.
Technical details from Drs. Fenerty and Pearce, Tel. 051-207 3581, Exts. 145/28.

Gut Biochemistry
(Dr. A. N. Mason)
Studies of the effects of dietary fibre on bacterial transformations implicated in diseases of the human intestine.
Informal enquiries to Dr. A. N. Mason, Tel. 051-207 3581, Ext. 144.
Applications, with curriculum vitae, and the names and addresses of two referees, should be sent to the appropriate supervisors named above. The address for all correspondence is—:

Department of Chemistry and Biochemistry
Liverpool Polytechnic
Byrom Street
Liverpool
L33AF **2441(F)**

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY
(in association with the Department of Dermatology, Leeds General Infirmary)

SRC (CASE) RESEARCH STUDENTSHIP

Applications are invited from students having a good honours degree in Biochemistry or a related subject for a three-year research studentship awarded by SRC available from 1 October 1979.

The proposed project is a study of normal and abnormal keratinisation in relation to various skin diseases (principally acne and psoriasis) and will involve the purification and characterisation of epidermal proteins and a study of the synthesis in normal and diseased skin. The value and conditions of the award will be those of SRC studentships. The successful candidate will be required to register for a PhD.

Applications giving curriculum vitae and the names and addresses of two referees, should be sent to Professor D S Robinson, Department of Biochemistry, (Telephone Leeds (0532) 36171). Closing date for applications 20 July 1979. 2421(F)

DEPARTMENT OF PHARMACOLOGY
INSTITUTE OF BASIC MEDICAL SCIENCES
ROYAL COLLEGE OF SURGEONS OF ENGLAND
Lincolns Inn Fields
London WC2A 3PN

Investigation of Inflammatory Mediators

Applications are invited from any discipline for a

POSTDOCTORAL RESEARCH FELLOWSHIP

to study chemical mediators of inflammation. The department has developed radio-isotopic techniques to measure plasma exudation and blood flow changes in animal models of inflammation. This is supported by other techniques such as radioimmunoassay, smooth muscle bioassay, isolated tissue perfusion and cell culture. Of special interest is the interaction between the prostaglandin system and the complement system. The position will be supported by a three-year MRC project grant awarded to Professor G. P. Lewis and Dr T. J. Williams. Salary on scale to £7,145 plus £502 London Allowance.

Enquiries and applications (two referees) as soon as possible to Mr W. F. Davis, Secretary, Institute of Basic Medical Sciences. 2411(E)

THE UNIVERSITY OF BIRMINGHAM
FACULTY OF MEDICINE AND DENTISTRY
DEPARTMENT OF IMMUNOLOGY (RHEUMATISM RESEARCH)

SRC CASE STUDENTSHIP

Applications are invited from graduates with a Hons. BSc degree (1st or 2 I) in Biochemistry or Biological Sciences for a 3 year research post starting on 1st October 1979, leading to a PhD degree. The project, in collaboration with the Boots Company Limited of Nottingham, will be concerned with the development and application of a rabbit model of arthritis.

Applications, together with the names of two referees, should be sent as soon as possible to Dr. D. R. Stanworth, Department of Immunology, University of Birmingham, Birmingham B15 2TJ. 2386(F)

UNIVERSITY OF STIRLING
BIOLOGY DEPARTMENT

SRC STUDENTSHIP IN ANIMAL OR PLANT BIOLOGY

tenable for 3 years leading to a PhD degree.

Applications giving two referees should be sent to Head of Department of Biology, Stirling University, Stirling, FK9 4LA as soon as possible. 2406(F)

UNIVERSITY OF ALBERTA
BIOCHEMISTRY DEPARTMENT

POST-DOCTORAL FELLOWSHIP

Apply to Dr A. R. Morgan, Biochemistry Department, University of Alberta, Edmonton, Alberta, T6G 2H Canada. Candidates must b knowledgeable in physico-chemical an metabolic aspects of DNA. The two mai areas in which the successful candidat would have a choice of doing researc would be multi-stranded nucleic acids an their possible biological roles (nucleoids chromosome condensation, tertiary structures) and DNA replication. Th position is available immediately. W213(E)

LANCHESTER POLYTECHNIC
At Coventry
FACULTY OF APPLIED SCIENCE
Department of Biological Sciences

NERC CASE RESEARCH STUDENTSHIP

The job: to work on the respirator physiology and energetics of Antarcti protozoa. The project will be jointl supervised by the Department of Biologica Sciences at the Polytechnic and the Lif Sciences Division of the British Antarcti Survey.

Required: applicants should have, o expect to obtain, a first or upper secon class honours degree in biological scienc and an interest in ecology, so microbiology or invertebrate zoology.

For application form and jo specification please apply in writin enclosing a large stamped and addresse envelope to the Personnel Officer Lanchester Polytechnic, Priory Stree Coventry. (Informal enquiries to Dr. H. G Smith, telephone (0203) 24166 Ext. 629 o to Dr. W. Block, British Antarctic Survey telephone Cambridge (0223) 61188 (Ext 256) returnable by Monday 16th July 1979. 2382(F)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS
Hallamshire Hospital, Sheffield

SRC CASE STUDENTSHIP

Applications are invited from men an women graduates with a good honour degree for an SRC CASE Studentship to b held in the above Department i conjunction with Reckitt and Colman Lt commencing in October 1979. The projec will involve an investigation of the factor affecting the systemic availability of som drugs administered via the oral route Suitable for individuals interested in th fields of drug metabolism and kinetics Applications should be sent to Professo H. F. Woods or Dr. G. T. Tucker at th Department of Therapeutics, The Hallamshire Hospital, Sheffield S10 2JE by 16 July 1979. Quote ref: R 332/G. 2403(F)

ICI PHARMACEUTICALS DIVISION
Alderley Park Cheshire

Case Research Studentships

The Science Research Council is offering SRC (CASE) studentships, tenable from 1 October 1979, to persons who already hold, or expect to obtain a First or Upper Second Class Degree. Applications are invited for the following projects which will lead to the degree of PhD:

The synthesis of stable analogues of thromboxane A_2	Prof. J.K. Sutherland, Chemistry Department, University of Manchester.
Metalloporphyrins as diamagnetic shift reagents	Dr. R.J. Abraham, Department of Organic Chemistry, University of Liverpool.
Organoiron complexes in organic synthesis	Dr. A.J. Pearson, University Chemical Laboratory, University of Cambridge.
Isolation and characterisation of drug conjugates	Dr. J. Caldwell, Department of Biochemical and Experimental Pharmacology, St. Mary's Medical School, London.
Alkylborane — amine complexes as reducing agents	Prof. A. Pelter, Department of Chemistry, University College, Swansea.
Routes to hydroxy 3-and 4-amino acids	Dr. C.M.C. Drey, School of Chemistry, Robert Gordon's Institute of Technology, Aberdeen.
Physiological and biochemical mechanisms in the development of pulmonary interstitial fibrosis	Dr. M. Griffin, Department of Biochemistry, Trent Polytechnic, Nottingham.
Aspects of gastric mucosal protection	Dr. A. Allen, Department of Physiology, The Medical School, University of Newcastle-upon-Tyne.
The effects of 5-hydroxytryptamine (5-HT) agonists and antagonists on brain 5-HT metabolism and release	Dr. C.A. Marsden, Department of Physiology and Pharmacology, University of Nottingham Medical School.
5-hydroxytryptamine receptors in cortical neurones	Dr. E. Szabadi, Department of Psychiatry, University Hospital of South Manchester.

The successful applicants will carry out their research under the principal direction of the Academic Supervisor indicated. In addition they will spend a minimum of 3 months during the tenure of the studentship working in ICI Pharmaceuticals Division laboratories at Alderley Park.

Applications, indicating the particular project of interest, and accompanied by a brief curriculum vitae and the names of two referees, should be sent as soon as possible either to the named Academic Supervisor or to:

Dr. N.F. Elmore, Research Collaborations Coordinator, Imperial Chemical Industries Limited, Pharmaceuticals Division, Mereside, Alderley Park, Macclesfield, Cheshire SK10 4TG. Tel: (0625) 582828.

2410(F)

THE INTERNATIONAL INSTITUTE OF TROPICAL AGRICULTURE

PMB 5320, OYO ROAD, IBADAN, NIGERIA

POSTDOCTORAL FELLOWSHIPS

The International Institute of Tropical Agriculture, one of ten institutes supported through the Consultative Group for International Agricultural Research, conducts research to improve the quantity and quality of the principal food crops of the humid and sub-humid tropics, such as cowpeas and other grain legumes, rice and maize and the root crops of the tropics, cassava, yam, sweet potato and cocoyam. Research is also conducted on the farming systems of the humid tropics and covers the areas of soils, economics, mechanisation and storage.

IITA awards as many as fifteen postdoctoral fellowships yearly to selected persons who have newly-acquired degrees of the level of the degree, Doctor of Philosophy. Through these fellowships, the Institute seeks to increase and strengthen the body of agricultural scientists with experience in dealing with problems of food crop production in the world's humid and sub-humid tropics.

Postdoctoral fellows are salaried and receive such benefits as subsidised housing, the use of a small car, medical and accident insurance, sick leave accrual and vacation leave accrual of two working days per month of service. Travel is provided for the fellow and his family from the place of residence to the Institute and return. Fellowships are for an initial period of one year with the possibility of extending for a second year subject to the results of a mutual review conducted around the eighth month of the fellowship. Because of housing considerations, the Institute is not able to award fellowships to applicants with families of more than one very small child.

GRAIN LEGUME IMPROVEMENT PROGRAM

Crop Physiology

Qualification desired: Recent PhD in Crop Physiology.

Research: To develop and validate in co-operation with program scientists from collaborating institutions a heuristic model to simulate the growth and yield of Cowpeas (*Vigna unguiculata*) in relation to variations in the environment.

The model will be based on the extensive data available from field and controlled environment studies conducted over the past five or six years. The objective will be to elucidate further the interactions between crop response and environment; to provide additional understanding of how the information now available can be used most effectively towards crop improvement; an equally important aim will be to highlight areas where further investigation is required.

Plant Breeding

Qualifications desired: Recent PhD in Plant Breeding.

Research: 1. Plan and implement a program to develop grain type cowpea (*Vigna unguiculata*) cultivars adapted for use in intercrop and relay crop systems with maize and cassava, suitable for different ecological regions of West Africa.

2. Develop a program for selection and testing of green-pod vegetable cowpea cultivars for use in the more humid environments.

CEREALS IMPROVEMENT PROGRAM

Entomology

Qualifications desired: Recent PhD in Entomology with strong background in crop pest resistance research. A knowledge of insect ecology and plant breeding would be an advantage.

Research: Integrated team research leading to development of resistance in maize and rice to their major African insect pests most of which are species of stem borers.

TUBER AND ROOT IMPROVEMENT PROGRAM

Sweet Potato Breeding

Qualifications desired: Recent PhD in Plant Breeding. Experience in breeding root crops will be an added advantage.

Research: Breeding and selection for drought tolerance, weevil and virus resistance, good storability and high yield.

Agronomy/Physiology

Qualifications desired: Recent PhD in Agronomy with strong background in Crop Physiology.

Research: Development of improved technological packages suitable for small farmer adoption for such crops as cassava, sweet potato, yams and cocoyams.

Entomology (two positions)

1. **Qualifications desired:** Recent PhD in Entomology with strong background in Host Plant Resistance. Experience with biological control of insect pests would be an advantage.

Research: Screening for host plant resistance in the field. Some laboratory work required. The place of principal residence will be Tanzania.

2. **Qualifications desired:** Recent PhD in Entomology with strong background in biological control of insect pests. A knowledge of spoken and written French would be an advantage.

Research: Biological control of insect pests of tropical root crops. Field and laboratory work requiring artificial rearing of insects, release and recapturing. The place of principal residence will be Zaire.

Pathology

Qualifications desired: Recent PhD in Plant Pathology with strong background in diseases of plants caused by fungus pathogens. Some background in the physiology of parasitism would be an advantage.

Research: Investigations on the Cassava (*Manihot esculenta*) Anthracnose Disease caused by *Colletotrichum spp.*, including the development of a screening program for host plant resistance to the disease.

FARMING SYSTEMS PROGRAM

Soil Fertility

Qualifications desired: Recent PhD in Soil Science with strong background in Soil Fertility and Analytical Chemistry.

Research: The effects of various methods of crop residue management and tillage systems on fertiliser use efficiency in the humid and sub-humid tropics.

Soil Physics

Qualifications desired: Recent PhD in Soil Physics, Agricultural Engineering (Water Management) or Hydrology.

Research: 1. Root growth and development in relation to soil profile characteristics and tillage systems.

2. Computer stimulation of hydrological balance over an agricultural watershed in the tropics. A strong background in hydrology (Agricultural Engineering) and capability of writing computer programs required for this research.

2444(E)

Athrofa Gogledd-dd Cymru
The North E Wales Institute
of higher education

KELSTERTON COLLEGE, CONNAH'S QUAY, DEESIDE, CLWYD

SRC CASE STUDENTSHIPS

Applications are invited for two SRC CASE Studentships, tenable from 1st October, 1979 for work on the following projects:

1. "Mechanism of lipid oxidation in aqueous emulsions", in collaboration with Unigate Ltd. Supervisor: Dr. J. C. Allen.
2. "Radioimmunoassay of polyamines", in collaboration with Ortho Diagnostics, Ltd. Supervisors: Drs. J. C. Allen and C. J. Smith.

The co-operating bodies will supplement the SRC Studentships by £250 p.a. Applicants should possess or expect to obtain 1st or upper 2nd class Honours, and should write as soon as possible, with curriculum vitae, to the Institute Registrar, North E Wales Institute, Kelsterton College, Connah's Quay, Deeside, Clwyd. CH5 4BR.

2426(F)

UNIVERSITY OF STRATHCLYDE

Applications are invited for

TWO POSTDOCTORAL RESEARCH FELLOWSHIPS IN POLYMER SCIENCE

in the

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

to examine the synthesis and physical properties of materials encapsulated in various polymer matrices. One post will be concerned with the investigation of the suspension polymerisation of various monomers in the presence of encapsulation materials. The other post will deal with the investigation of the electrical properties of these and related materials.

Applicants should have either a background in synthetic chemistry, or polymer science or experience in dielectric or related physical measurements.

The appointments will be from 1st October 1979 and will be on Range IA of the national salary structure for research and analogous staff; Commencing salary within the Range £4,333 to £5,488 dependant upon age and experience.

The appointments are for one year with probable extension to three years.

Applications accompanied by a Curriculum Vitae and the names of two referees (quoting R25/79) should be sent to Dr. R. A. Pethrick, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow, G1 1XL.

2389(E)

UNIVERSITY OF WARWICK

SRC (CASE) Chemistry Research Studentship New Cationic Photopolymerisation Initiators

Applications are invited for a three year SRC (CASE) Research Studentship in the Department of Chemistry and Molecular Sciences, starting 1st October, 1979, and supervised by Dr. T. J. Kemp in collaboration with Ozalid (UK) Ltd.

The project involves development of new compounds releasing initiating centres for polymerisation on photoirradiation in an image-wise manner. Applicants should hold, or expect to hold, at least an upper second class honours degree in chemistry. Further details may be obtained from Dr. Kemp, Department of Chemistry and Molecular Sciences. Applications, with the names of two referees, should be sent as soon as possible to the Academic Registrar, University of Warwick, Coventry CV4 7AL. Please quote Ref. No. PG/42/79.

2435(F)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF GEOLOGY

NERC CASE STUDENTSHIP

Applications are invited for a NERC CASE Studentship for research into the mineralogical properties of clays which are of importance in the development of colour in fired building products.

The successful applicant will spend two months each year at the Redland Technology Laboratories at Horsham in Sussex — additional payments will be made for this.

Applicants should have a good honours degree in Geology/Mineralogy/Ceramics or a related discipline.

Further information may be obtained from Professor J. E. Prentice, Dept of Geology, King's College, Strand, London WC2R 2LS, to whom applications should be sent as soon as possible.

2370(F)

MIDHURST MEDICAL RESEARCH INSTITUTE

West Sussex GU29 0BL

Applications are invited for a C.A.S.E. studentship, to work on the Histrochemistry and Biochemistry of Atherosclerosis.

The work can lead to a higher degree, will be carried out at the Institute, and the May and Baker Laboratories.

Applications should be addressed to Dr R. Butcher at the above address. 2415(F)

UNIVERSITY OF NEWCASTLE UPON TYNE

MRC STUDENTSHIP IN GENETICS

Applications are invited for an MRC studentship on a project concerned with plasmid-coded restriction and modification systems. The work will involve both genetic and physical techniques in the study of bacterial plasmids.

Applicants who have an upper second or first class degree should apply *as soon as possible* to Professor S W Glover, Department of Genetics, Ridley Building, Claremont Place, The University, Newcastle upon Tyne NE1 7RU. 2395(F)

Commonwealth of Australia

"QUEEN'S FELLOWSHIPS IN MARINE SCIENCE"

To commemorate the Royal visit to Australia in 1970 the Australian Government established the Queen's Fellowships Scheme. Under this scheme up to five fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proved capacity for original work. These awards are tenable at an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen's Fellows should have a Ph.D., or equivalent qualifications, or equivalent research or professional experience, in a discipline applicable in marine science such as coastal engineering. Awards will, in general, be restricted to applicants who are not more than 30 years of age on the date when applications close.

STIPEND: $17131 (Australian) per annum – increased to $18403 per annum at age 28 years.

ALLOWANCES: Allowances are payable in respect of a Fellow's dependent spouse ($500 p.a.), each dependent child ($200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses.

APPLICATIONS: Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen's Fellowships Committee, Department of Science and the Environment, P.O. Box 449, Woden. A.C.T. 2606 Australia; The Minister (Scientific), Canberra House, 10–16 Maltravers Street, London WC2R 3EH; or the Australian Embassy, 1601 Massachusetts Avenue, Washington D.C. 20036, U.S.A. Applications for the next round of awards, which will be announced in December 1979, close at the Canberra address on 17 August 1979.

2383(E)

UNIVERSITY OF GLASGOW

CHEMISTRY DEPARTMENT AND ICI ORGANICS DIVISION

Applications are invited for an SRC CASE Research Studentship tenable from October 1st, 1979, to study the synthesis and applications of polycyclic organo-sulphur compounds. Applicants, who must hold, or expect to obtain by October, a First or Upper Second Class Honours Degree (or equivalent qualification) in chemistry, should send a curriculum vitae and the names of two referees to Dr P. H. McCabe, Department of Chemistry, University of Glasgow, Glasgow, G12 8QQ. 2424(F)

UNIVERISTY OF NOTTINGHAM

FACULTY OF AGRICULTURAL SCIENCE

SRC (CASE) RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship to investigate the relationship between the structure and the texture and appearance of a new type of food gelling agent. The project is in conjunction with a leading food manufacturer and will be aimed at obtaining increased understanding of this novel material. The successful candidate will be required to adopt a multidisciplinary approach and work in close collaboration with the Company concerned.

The successful applicant will be expected to register for the degree of PhD. Candidates holding a degree in Chemistry, Physics, Food Science or Biochemistry should apply to Dr. J. R. Mitchell, Department of Applied Biochemistry & Nutrition, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics. LE12 5RD, enclosing a brief curriculum vitae. 2372(F)

UNIVERSITY OF TORONTO CLIMATE-RELATED RESEARCH

Applications are invited for two post doctoral fellowships at the University of Toronto. One position is for a climate modeller interested in the CO_2 problem; the other is for a social scientist interested in the impact of climate change on society. Application deadline: 1 August, 1979. Salary range and conditions of employment are those of the Canadian NRC. Apply to Prof. F. K. Hare, Director, Institute for Environmental Studies, The University of Toronto, Toronto, M5S 1A4, Canada. W202(E)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF NEUROLOGY

A Postgraduate Research Studentship is available for three years from October 1st, 1979 at the Regional Neurological Centre. The work will be concerned with the enzymology of protein breakdown in muscle. There is a large unit studying various aspects of muscle diseases at the Regional Neurological Centre. Applicants should have or expect to obtain a good Honours degree with biochemistry or chemistry as a major subject, and the successful candidate will register for a PhD degree. Remuneration will be the same as that of postgraduate students supported by the Medical Research Council.

Applications, including the names and addresses of two referees should be sent, as soon as possible to Dr R. J. T. Pennington, Neurochemistry Department, Regional Neurological Centre, General Hospital, Newcastle upon Tyne NE4 6BE. (0632-738811.) 2343(F)

INSTITUTE MARINE BIOCHEMISTRY

Applications are invited from recent Graduates in Biochemistry with at least an upper 2nd class honours degree for a NERC Research studentship. The work will be concerned with the normal Biochemical mechanisms — minimise the peroxidation of membrane lipids in wild and cultured fish and with the effects of peroxidized lipids in the diets of cultured fish.

It is envisaged that the work will form part of the requirements for the degree PhD from the University of Aberdeen.

Apply with curriculum vitae including the names of two academic referees to:

The Director
Institute of Marine Biochemistry
St Fitticks Road
Aberdeen AB1 3RA.

By Monday 23rd July, 1979. 2431(F)

BRUNEL UNIVERSITY

DEPARTMENT OF PHYSICS

Applications are invited from scientists and engineers for a

RESEARCH STUDENTSHIP

in the lively and friendly electro-optics group of this department. The studentship is funded by the S.R.C. for a period of three years, leading to the PhD degree. It is a CASE studentship, in collaboration with Unilever Research Ltd, for the study of the electro-optical properties of

LYOTROPIC LIQUID CRYSTALS

Applicants should be British citizens and have a first class or upper second class degree. Please contact Professor B. R. Jennings, Electro-Optics Group, Physics Department, Brunel University, Uxbridge, Middlesex UB8 3PH. Telephone Uxbridge 37188. 2433(F)

LINCOLN COLLEGE
(University College of Agriculture)
New Zealand

POST-DOCTORAL FELLOWSHIP

The Council of Lincoln College invites applications for a Post-Doctoral Fellowship, tenable in any of the following Departments:
Agricultural Economics and Marketing; Agricultural Engineering; Agricultural Microbiology; Animal Science; Biochemistry; Entomology; Farm Management and Rural valuation; Horticulture, Landscape & Parks; Plant Science; Range Management; Soil Science; Veterinary Science; Wool Science.

The object of the award is to contribute to the research programme at Lincoln College. In addition to carrying out research, the successful applicant will be expected to participate in limited teaching activities without further emolument.

The Fellowship will have a total value of NZ$10,000, part of which will be available for fares. Tenure will be for one year in the first instance, but may be extended at the discretion of Council.

Conditions of Appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications for the Fellowship close on 15 August 1979. 2437(E)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications are invited for a three-year MRC-financed research fellowship. Salary will be on the RF IA scale £4,333 to £7,521 (to operate from 1st October 1979) plus superannuation. Starting salary will be up to £5,488 according to age and previous (not necessarily related) postdoctoral experience.

The project is to study the chemical changes in virus-infected cells both *in vitro* and *in vivo* by X-ray microanalysis of frozen, freeze-dried unstained sections of cells. Observed changes will be correlated with virus-induced changes in patterns of polypeptide synthesis analysed by conventional techniques. The work will be carried out in two laboratories under the supervision of Dr. J. Stephen (Department of Microbiology, Birmingham University) and Dr. T. A. Appleton (Department of Physiology, Cambridge University). Full provision has been made for travel between the two institutions and stays of short duration in Cambridge.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P O Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees, should be sent by Friday 27 July, 1979. Please quote ref NM6. 2397(E)

THE UNIVERSITY OF MANCHESTER

A research studentship is available for candidates holding or expecting to gain a good honours degree in a Biological Science (including Pharmacology and Immunology) for an investigation of experimental arthritis in primates and other mammals. The programme, under the direction of Professor D. L. Gardner, is intended to provide the opportunity to study for a PhD of this University. Applications and enquiries should be addressed to Professor D. L. Gardner, Department of Pathology, University of Manchester, Stopford Building, Oxford Road, Manchester, M13 9PT. 2377(F)

UNIVERSITY OF NOTTINGHAM
MEDICAL SCHOOL

RESEARCH STUDENTSHIP IN MICROBIOLOGY

Applications are invited for a Research Studentship in Microbiology leading to the degree of PhD for work on the continuous monitoring of the action of antibiotics on dense bacterial cultures.

Applications with the names and addresses of two referees to Professor F. O'Grady, Department of Microbiology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH. 2374(F)

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for an SRC CASE Studentship for three years from 1 October 1979 under the supervison of Dr M. A. Rosemeyer in collaboration with G.D. Searle and Co. Ltd. (High Wycombe). The project is to develop agents to prevent polymerisation of haemoglobin in sickle-cell disease.

Applicants should have a good honours degree and will be expected to register for a PhD.

Further details can be obtained from Dr M. A. Rosemeyer, Department of Biochemistry, University College London, Gower Street, London WC1E 6BT, to whom applications with curriculum vitae and the names of two academic referees should be sent as soon as possible. 2371(F)

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF BACTERIOLOGY AND VIROLOGY

The North West Water Authority is funding a three-year postgraduate studentship in microbiology which will be primarily concerned with the development of standard methods for the quantitative estimation of salmonellae strains in sewage sludge. Maintenance grant payable: around £2,000 p.a. The successful candidate will register for a higher degree, probably at MSc level for one year but renewable for a further two years for a PhD, subject to satisfactory academic progress. The award is tenable from October 1st, 1979. Particulars from Professor P. Collard, Department of Bacteriology and Virology, University of Manchester, Stopford Building, Oxford Road, Manchester M13 9PT. 2380(F)

THE UNIVERSITY OF SHEFFIELD

SRC RESEARCH STUDENTSHIPS IN SPACE PHYSICS

Applications are invited from men and women with a class 1 or 2:1 Honours Degree in Physics, Engineering or Maths. The vacancies are in the field of Magnetospheric Physics involving ground based, rocket and satellite observations. Please reply immediately to Professor T. R. Kaiser, Department of Physics, the University, Sheffield S10 2TN giving full curriculum vitae and names of two referees. Further details may be obtained by telephoning 0742 78555 Ext. 4277. Quote ref: R335/G. 2427(F)

ASSISTANTSHIPS

DEPARTMENT OF GEOLOGY
POST-DOCTORAL RESEARCH ASSISTANTSHIP

Applications from suitably qualified Geologists, Materials Scientists, Physicists or Chemists, are invited for a NERC-funded Research Assistantship to be filled at post-doctoral level. The position is with a group, directed by Dr. S. White and K. Brodie, studying the effects of deformation on metamorphic reactions and on mineral chemistry. The successful applicant will work on the micro-analysis, using TEM and STEM, of naturally deformed minerals. Particular attention will be paid to the development of metamorphic foliations during deformation. Previous micro-probe or TEM experience is required.

The appointment is tenable for three years and would start as soon as possible but preferably not later than January 1980. Salary in range £4762-£7647 inclusive according to age and experience.

Further particulars can be obtained from Dr. S. White, Department of Geology, Imperial College of Science and Technology, London SW7, to whom 2 copies of applications, giving a curriculum vitae and the names of two referees should be sent as soon as possible.

2456(P)

POSITIONS WANTED

MICROBIOLOGIST
(PhD, England 1978)/Pharm. D

Strong background in lipid biochemistry (discovery and characterisation of sphingalipids in bacteria, temperature effect on lipids), experience in fungal viruses, electron microscopy, centrifugation techniques, seeks research position in US or Canada. Box 2407(B) Nature 2407(B)

CONFERENCES

THE CITY UNIVERSITY
DEPARTMENT OF CHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANTSHIP

Organic Chemists with interests in biological chemistry are invited to reply for a Post Doctoral Research Assistantship to work in collaboration with Dr J B Hobbs on the synthesis of novel nucleosides with potential antiviral activity. The appointment is tenable for one year from 1st October 1979. The salary will be £4,333 p.a.; (under review) + £502 p.a. London Allowance and USS Superannuation Benefits.

Applicants should submit a curriculum vitae and the names of 2 referees to Dr J. B. Hobbs, Department of Chemistry, The City University, Northampton Square, London EC1V 0HB, as soon as possible and not later than 31st July 1979. 2381(P)

Be specific

Receptor-specific proteins from Pharmacia Fine Chemicals.

	Specific for:
Concanavalin A*	**D-Glucose/Mannose**
Soybean Lectin	**N-acetyl-D-Galactosamine**
Lentil Lectin*	**D-Glucose/Mannose**
Wheat germ Lectin*	**N-acetyl-D-Glucosamine**
Helix pomatia Lectin*	**N-acetyl-D-Galactosamine**
Protein A *(S. aureus)**	**F_C region of immunoglobulin G**
FITC-Protein A	**F_C region of immunoglobulin G (fluorescent, for microscopy)**

***Also available Immobilized on Sepharose®, for use in affinity chromatography.**

Receptor-specific proteins are valuable reagents in cell studies because of their well-defined interaction specificities. You must be able to rely on them being pure, biospecific and fully active. You can when you purchase your receptor-specific proteins from Pharmacia Fine Chemicals, the leader in the field of protein separation technology.

Contact Pharmacia today for technical information on receptor-specific proteins.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

The Skylab syndrome

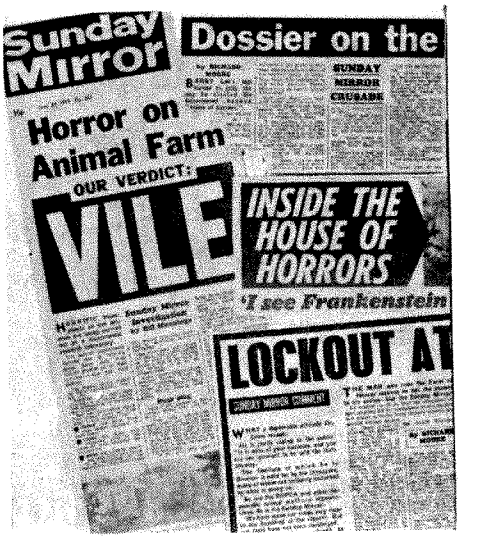
There has been something deeply symbolic about Skylab's ungainly descent back down to earth. After all, it is almost ten years to the day since the US successfully carried out what many consider to represent the pinnacle of its scientific and technological achievement: placing a man on the surface of the moon. The deed did, indeed, turn out to be a turning point, but perhaps not in the way that those responsible for the lunar programme intended. For it took place on the eve of a decade in which mankind has turned its technological concerns away from the stars and back to its own planet, and to the more mundane, but no less complex, concerns such as health, energy and natural resources that have become the new prime targets for research. Skylab's demise comes on the eve of a new decade; and its message, which seems likely to become a dominant political theme in the years ahead, is that high technology frequently carries a built-in risk factor which, if not adequately planned for, will return to haunt us with its own particular form of revenge.

The whole incident could not have occurred at a worse time for the National Aeronautics and Space Administration. The agency's public image is currently being seriously tarnished by a set of technical problems, and related cost over-runs, in the space shuttle development programme. These problems have forced the agency, for the first time in many years, to go back to Congress cap in hand to request a substantial increase in funding over what had previously been agreed. With Congress already doing what it can to reduce expenditure across the whole federal budget, NASA's case has not been helped by an incident which links the agency directly to other areas of public concern over the dangers of high technology, in particular the Three Mile Island accident and the DC-10 aircrash. And although it seems likely that the extra money will be forthcoming — largely because of the military importance of space shuttle for launching satellites and carrying out surveillance tasks — other areas of NASA's activity may be made to suffer as a result.

At one level, both the problems with Skylab and the space shuttle can be attributed to the consequences of working with tight financial budgets. Skylab's designers saved $10 to $20 million by not adding engines that would have boosted the space station in its orbit when it began to slip back to earth, enabling it to be kept in orbit until it could be reached by space shuttle (the shuttle was initially expected to be launched this year, and Skylab to stay in orbit until 1983). And in the case of the shuttle itself, delays have been caused largely as a result of the development programme being planned according to a success-oriented strategy, with minimum back-up to allow for problems.

But it has not only been a question of money; there is also the question of control, and the associated attitude towards risk-taking. With space shuttle, the main contractor for the engine development has admitted to a certain laxity in overseeing the development of the programme, and has announced moves to remedy this situation by establishing close links between the technical and the financial staff. In Skylab's case that lack of adequate control, manifest in a more direct sense, has given rise to problems far too late for anything to be done.

The lesson of both would, in different ways, appear to be obvious: that in developing high technology with a potentially significant social impact, mechanisms to ensure adequate control of the technology should be developed at the same pace as the technology itself. The problem is that although this prognosis has logic on its side, it runs directly into conflict with the ideology of a system which rewards technological ingenuity rather than social responsibility. The market-place, rather than the political process, has been treated as the proper forum for weighing risks against benefits; and those who have introduced new technologies have, as a result, felt no responsibility for the way that purchasers choose to make use of them. Indeed a surfeit of regulation — society's attempt to control the various non-market impacts of technology — has been increasingly criticised in recent years for its impact on the innovation process; and pressures are growing both in the US and, in line with the new government's current ideology, in the UK to return to the market place in its purest form as the prime regulatory agency.



Such programmes are, as their supporters point out, intentionally risky ones; only, they would argue, by encouraging people to take risks — and subsequently to reward those whose risks pay off — can vitality be reintroduced into the economic system. But such an approach is also predicated on the basis that the losers will suffer; and the particular concern generated by high technology is that the economic gains generated by the risk-taking of some will be outweighed, not so much by the losses of unsuccessful risk takers, but by the broader impact of failure upon those excluded from the decision-making on the risk in the first place.

What has concerned people most about Skylab is not so much the fact of its re-entry as the virtual total lack of control over its descent. Just as in the case of the Three Mile Island incident, it was the involuntary aspect of exposure to radiation emitted from the plant, rather than the actual level of exposure (compared, for example, to normal background radiation), that generated the fiercest complaints. Equally control cannot be reduced simply to a managerial or technical function, but must be seen to reflect a broad sense of responsibility to the whole community.

It would be a tragedy if the dominant message left by the Skylab incident, following as closely as it does the other high technology accidents that have occurred this year, merely frightened people away from such technology on principle. However if what comes through is that the control of technology is as important as the technology itself, then the lesson will have been worth-while. Perhaps this is the most significant theme to have emerged from recent debates about the concept of "appropriate" technologies, both in developed and developing countries; perhaps, too, it is one that we can learn to put into action in the decade ahead. □

Nature Vol. 280 12 July 1979

UK research council hits back at 'horror lab' allegations

THE UK Agricultural Research Council last week held a press conference to present journalists with a defence of its use of animal experiments, after the *Sunday Mirror* had published 'shock' accounts (see right) of experiments at the ARC's principal laboratory, the Institute of Animal Physiology at Babraham near Cambridge. "Scientists transplant udders!" said the *Sunday Mirror*, and "Our verdict: vile".

But last week the director of the centre, Dr Barry Cross, countered that the story was "a statement about human reaction, not about animal cruelty". He questioned the credentials of the *Sunday Mirror*'s two witnesses of what went on at the institute. The first, Dr Cross said, "was a grade EW6 technician — the lowliest form of human life — no O-levels, no CSEs", and he was remembering 10 years after the event. The second "was a window cleaner or an asphalter who strayed from his proper job". To an expert, their reports "indicate pain and distress on the part of the unqualified observer".

Dr Cross's response was perhaps not calculated to enlist the sympathy of the journalists from the popular press (the *Star*, the *Express*, the *Sun*, the *Daily Mirror* and the *Sunday Mirror* were present); but the statement that followed was.

"I'm not here to defend cruel experiments on animals", Dr Cross said. "I was the first student president of the Union for Animal Welfare". Cruel experiments "would frustrate all our work — because we are studying healthy animals".

The experiments questioned by the *Sunday Mirror* involved udder transplants in goats and cows, to investigate secretions into the milk; permanent access to the animal's stomach, to investigate the digestion of the rumen; and an operation to bring a vein in the neck closer to the surface, to allow less painful injections to be made.

The ARC scientists have developed techniques, involving skilled surgery such as would "shame the National Health Service", which induces only mild post-operative pain while the wounds are healing, said Dr Cross. After that, the animals enjoy "a life of 5-10 years of cossetted living".

Stress levels in the animals are remarkably low. A researcher attempting to measure cortisol levels — a stress indicator — in Babraham cattle was shocked to discover amounts well below textbook levels. At first he thought that the Babraham cattle must be of a particularly phlegmatic strain, thus disqualifying many previous experiments, but then the cortisol shot up to the standard level when a noisy visitor entered the room. "Animals are more stressed on a farm than in our laboratory", said Dr Cross. "Our animals are the friendliest I know. They don't expect hostile people."

Moreover, said Dr Cross, referring to the case of a goat udder transplant, which appears to have caused most public reaction, a new-born kid actually prefers the transplanted teat, "and he must be considered unbiassed".

"We have never been refused a Home Office licence" said Dr Cross. (The Home Office controls animal experiments through the 1876 Cruelty to Animals Act.) "I've only been a director at Babraham for five years; previously I've worked in seven laboratories in the US, Scandinavia, and the UK, and I've visited many hundreds of others, and I have never seen a standard of care that surpasses or even equals Babraham's."

Dr Cross also defended the Babraham work on scientific, economic, and medical grounds. "One in seventeen women suffer from breast cancer", said Dr Cross, "but ruminants do not. Our experiments may give a clue to what predisposes women to this." Tranquillisers derived from experiments in the 1940s and 1950s on the effects of drugs on animal brains. The contraceptive pill based on hormones secreted by the ovary, a lot of work on which was done at Babraham. Furthermore, "there is a lot of evidence" that the brain is altered by sex hormones at a very early period, and there is a question of injurious effects from the mother's milk if the mother is on the pill. The basic work on the udder at Babraham may shed light on this, said Dr Cross.

More direct agricultural benefits have been: pregnancy tests, synchronisation of oestrus in herds of cows to save veterinary labour, the use of prostaglandin to induce pigs to give birth in daylight (which reduces mortality), the improvement of animal welfare in intensive production, a reduction in methane production in the digestion of cattle (so lowering energy costs), and the protection of plant protein in the rumen (so increasing the conversion efficiency of plant to animal food). "If you lock up Babraham, you lock up these advances", said Dr Cross.

It was also "a complete myth" that Babraham concealed its work. The institute has produced 2,700 scientific publications, and nine biennial reports — with photographs. Large numbers of the public have been admitted — 12 parties a month of students, farmers, foreign correspondents "and all sorts of layman" pass through. In the past 18 months there have been four visits from journalists; four TV teams; and three broadcasts.

Nevertheless Dr Cross refused to allow *Sunday Mirror* journalists, whom he called "propagandists", or photographers into the laboratory; but there was an agreement to allow an observer acceptable to both sides. Subsequently (8 July) the *Sunday Mirror* commented: "He is really saying to the public: 'It's none of your business, and you are too ignorant to be told the facts anyway' ".

Meanwhile, Jean Pink, organiser of the anti-vivisection group 'Animal Aid', has claimed that the *Sunday Mirror* is prepared to give further press coverage to the "diabolical tests", and will photograph demonstrators outside the Institute on Saturday.

Robert Walgate

Polish science writers go too far

Last month the Polish media celebrated the first anniversary of the flight of Cosmonaut Miraslaw Hermaszewski. Ironically, their special features coincided with a growing disillusion among Polish scientists not so much with the space programme itself but with what they see as its propaganda exploitation — notably in the case of the controversial 'Syrena' results.

'Syrena' was a Polish-designed experiment, carried out aboard the Salyut-6 space station, in order to obtain semi-conductor triple crystals of mercury, cadmium, and tellurium using a gradual cooling method and of mercury, cadmium and selenium, using gas phase sublimation. In order to maintain controlled conditions of weightlessness, the production of the crystals, using the Soviet-built 'Splav' furnace, was carried out during the cosmonauts' rest period, lest undue motion disturb the space-craft.

Nevertheless, last autumn, Hermaszewski intimated to *Nature* that he had got up several times during the 'night' to ensure that the experiment was working properly, since the project, named after the symbol of Warsaw, had considerable national significance.

0028-0836/79/280094-02$01.00

© Macmillan Journals Ltd 1979

Not surprisingly, initial reports in the Polish media claimed the experiment as an unqualified success. Monocrystals of high homogeneity were it was said, obtained, such as would be totally impossible to produce under conditions on Earth. Then in February 1979, a meeting was organised in Krakow by the Japan Electro-Optics Laboratory for Polish users of its equipment.

A paper presented here by Warminski and Zahorowski of the Institute of Physics of the Polish Academy of sciences indicated that 'Syrena' had simply yielded a mixture of crystals of various compositions, in which the degree of homogeneity and the composition of the specimens depended on experimental parameters such as temperature gradient.

This would not in itself have disconcerted the scientists — a negative result is also of scientific value — had they not felt the results had been deliberately exaggerated by the media, which had claimed the alleged hyper-homogeneous triple crystals as a triumph for Polish science within the framework of "Interkosmos" (the Comecon space programme). "Science has become a state prostitute!" one young physics graduate put it.

Nor, apparently, was the disillusion confined to the lower echelons. According to a circumstantial report published by the "opposition" (i.e. underground) *Biuletyn Informacyjny KOR*, Professor Adam Gierek, the son of the party leader, remarked to a prestigious gathering of specialists that 'Syrena' has brought us back from space to Earth with a bump!"

The disappointment with 'Syrena' does not, however, extend to the Polish Academy of Sciences. Dr R. Galazka, of the Institute of Physics, who presented the results of the 'Syrena' experiments at the European Space Agency Conference in Grenoble in April, told *Nature* that "it was not our aim to produce crystals for some specific purpose, but to check the process of crystallization in space. We were able to use a diffusion controlled technique, impossible on Earth, to get crystals with some parts up to 50% homogeneous. Also we were able to study the problem of cavitation under pressure. We never aimed at getting a single crystal — indeed the technique of the experiment made this impossible. But we did get some 5mm single crystal blocks".

Professor Stanislaw Grzedzielski, of the Academy's Institute of Space Research, had just returned from a discussion with Dr Jan Kaczmarek, Academic Secretary of the Academy (a post which carries Ministerial rank) on the future of the space programme. He told *Nature* that plans for 1981-85 would include projects taking into account the results of Syrena. These results, he said, were not strictly speaking a surprise "because we simply did not know what to expect. Had we known, we need not have done the experiments."

Any exaggerated claims in the media, he said (and he himself always avoided popular science features), must have been due to patriotic zeal on the part of the reporters and/or their inability to understand the nature of the experiment. Even in a "controlled" press, he intimated, such divergencies can and do occur.

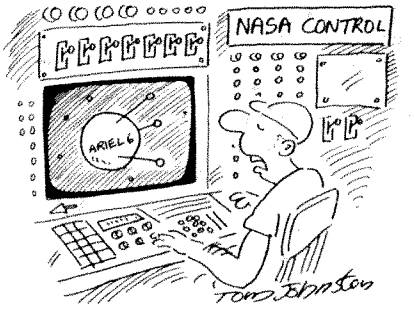
He himself, although not an expert in materials science, was not unhappy with the results. "Had they simply obtained perfect monocrystals every time", he said, "then there would be nothing more to find out, and the matter would no longer be one of space science but only of space technology. As it is, we can do a lot more experiments. Indeed it is expected that the Americans will try to replicate our work."

"Now that the work has started," he added, "it is far too valuable to stop. And it is very cheap, too. You see, it is not true that it involves 'cosmic sums of money' as some people would like one to believe. We don't pay for the 'ride' at all — the place on the rocket, the launch, ground control systems and so on. We only pay for the apparatus produced in Poland, and the associated data processing etc."

The Soviet Union, he explained, were so far prepared to provide launch facilities free. "Fraternal solidarity is very important to them. If you are a big power and want your neighbours as friends you have to give them something they wouldn't have had otherwise".

This assurance, if passed on to the Polish public, would doubtless allay the rumours that 'Syrena' cost "several tens of millions of dollars" (from Poland's scanty hard-currency reserves) — if, of course the public were to believe it. Disillusion with the reporting of 'Syrena' however, bids fair to percolate from scientific circles to the wider public — carrying with it a disillusion with all forms of science reportage. It is perhaps not without significance that at this year's meeting of the Polish Academy of Sciences, a determined effort was made to bring forward a resolution calling for an end to press censorship — a motion which was thrown out by an amendment proposed from the chair. **Vera Rich**

Mystery beams affect UK satellite



BRITISH scientists are mystified by signals emanating from regions around British Columbia and the Caspian Sea that are turning off high voltage supplies in the UK research satellite, Ariel 6. After each satellite orbit over the areas, the high voltage of two experiments is switched off while a third supply is completely unaffected. The commands controlling the switching consist of a 148.25MHz carrier with a 5kHz subcarrier carrying the command signal so the interfence has to be highly specific in order to affect two supplies but not the third. Dr Len Culhane Chief Project Scientist in Mullard Space Science Laboratory's X-ray astronomy group has no explanation. "We think the signals are being generated spuriously but we can't figure out how."

Five additional NASA ground control stations have been brought into play to turn the switches on after the satellite passes through the regions. Culhane is hopeful that eventually the satellite can be brought up to 80% of its operational capacity by further interventions.

Two other features of the interference puzzle the experimenters. First the interference occurs only when the Sun is shining on British Columbia or the Caspian. And second the experimenters have discovered that the satellite can be "immunised" against being switched off by beaming pure carrier frequency at it just before it enters the mysterious zones. The satellite orbits are such however that the satellite passes close enough to a neighboring ground station only 30% of the time — thus it cannot be immunised completely. Alan Wells of the Mullard group thinks that the likely cause is a jolt effect — a ground based radio signal combines with electrical noise in the space craft to produce coding signals that activate the equipment switches. The possibility that the interference has been caused by vhf blasting signals coming from a dam construction site has been ruled out as has the possibility that interference is random.

In spite of the mystery the spacecraft is taking useful data. A Bristol University experiment on ultra heavy cosmic ray nuclei ($26<Z<92$) using a gas Cerenkov counter has been unaffected. The two X-ray experiments, one by Leicester University and the other a Mullard-Birmingham University collaboration has been fortunate enough to observe an X-ray burst from the X-ray source 1735-444 which was one of the hoped for observations of the mission. However a solar panel experiment designed by the Royal Aircraft Establishment at Farnborough has been unable to operate.

But short of some unexpected revelation it is likely that the reason for the interference will not be found, leaving the possibility that a space variant of the Bermuda triangle legend may be in the making. **Joe Schwartz**

"As it's a British satellite, it's probably just taking a tea-break!"

UNCSTD success still hangs in the balance

David Dickson reports from New York on final preparations for the UN Conference on Science and Technology for Development

With less than six weeks to go before official proceedings open in Vienna, a cloud of uncertainty still hangs over the chances of any major achievements coming out of the United Nations conference on Science and Technology for Development.

Delegates attending the fifth and final meeting of the conference's preparatory meeting in New York last week managed to reach agreement on a number of proposals that will be put to the conference as part of a 'plan of action' which the conference will be urged to adopt. However there are still major differences in three of the key areas to be discussed — the transfer of technology, and the institutional and financial procedures necessary to implement the decisions of the conference — and the stage has now been set for some hard bargaining over these in Vienna.

In general, the developing countries are seeking ways to improve their bargaining position over acquiring technology from the industrialised countries, to gain additional funds from these countries to build up their scientific and technological efforts, and to make the UN system more responsive to their needs in these areas by increasing their control over the relevant decision-making processes. In contrast, the industrialised countries, quoting domestic, economic, and political problems of their own, are keen to discuss specific areas of scientific and technological assistance, but have so far been digging their heels in over agreeing to any major procedural changes or financial commitments.

Most of the two-week session was spent by delegates in closed drafting meetings discussing, paragraph by paragraph, proposals for a new plan of action. The plan has been compiled by the Group of 77 (to which over 120 developing countries now belong) as an alternative to proposals put forward by the conference secretariat.

Agreement was reached on a number of proposals, mostly on relatively uncontroversial areas dealing with the internal arrangements that developing countries should make in order to increase their scientific and technological capabilities.

There were difficulties, however, whenever a paragraph arose that involved — or seemed to involve — the developed countries making any type of commitment to change existing arrangements. The developing countries have essentially used the proposed plan of action as the occasion to make a detailed statement of principle on what, they feel, should be done by developed countries and the United Nations bodies in the area of science and technology for development. In contrast, the developed countries — with a few notable exceptions, particularly the Nordic countries — claim that such statements imply definite commitments of the type which many of the negotiators said they were unable to make.

The result is that when delegations arrive in Vienna, they will be faced with a series of documents liberally peppered with square brackets containing alternative formulations of key proposals. For example, where the Group of 77 suggests that the plan of action say "developing countries should be able to play a more effective role at the decision-making level in international organisations", the EEC suggests the same paragraph should read "all countries should . . . ". Similarly, where the developing countries are demanding "full access" to western technology, the developed countries want this changed to "freest and fullest possible" access, a qualifier that dilutes the initial intent.

Three areas of disagreement remain. The first is the general area of technology transfer. Here the developing countries, in line with the stance taken in other UN forums, are demanding substantial concessions in their terms of access to the technology of the developed world. Industrialised countries, in contrast, are refusing to make any significant concessions, arguing partly that this is the responsibility of the private sector over which they have no control, and also that the issues are already being dealt with sufficiently elsewhere. The second area of disagreement is over the financial support needed to carry out the conference's recommendations. The Group of 77 argue that this can only be done with a considerable increase in the transfer of funds from the developed countries. They have suggested setting up a new financing system, largely financed by the industrial world, with a provisional target of $2 billion by 1985 and $4 billion by 1990.

The industrialised countries, however, have made clear their reluctance to commit themselves to any increase in such contributions. They are particularly critical of the suggestions that they be required to make "automatic" contributions to such a fund on the basis of, for example, their trade surplus in manufactured goods with the developing world.

Financial issues are also linked to the third area of disagreement, namely what changes should be carried out in the UN system to implement the conference proposals. The developed countries would like to see the strengthening of existing bodies, in particular the UN's economic and social council, to do this, although accepting that the status of science and technology should be raised within general development strategies.

In contrast, the developing countries, distrusting what they consider to be the undue dominance of the industrialised countries in ECOSOC, want a new intergovernmental body to be set up. This might report directly to the General Assembly, with an executive general secretariat possibly established under the recently created UN post of Director-General for Development and International Co-operation.

A critical factor in this debate is likely to be the United Nations Development Programme. Although it has so far done relatively little explicitly concerned with science, UNDP has both wide experience of development issues and a high credibility among third world countries, and it may well be given operational responsibility, with an increase in funds, for decisions made by the intergovernmental committee in line with UNCSTD's final recommendations.

One phenomenon noted by a number of delegates at the meeting was an apparent softening of the US negotiating tactics. According to those who attended the closed drafting sessions, whereas the US had previously been pushing a relatively hard line in negotiations, disputing even relatively small points, they have subsequently slightly relaxed their stance, leaving the hard line more to the EEC countries ("and the British were the toughest of the lot" said one South American delegate).

Some have suggested that this shift in tactics may partly reflect a change of strategy by the transnational companies, eager to maintain their links with third world markets, but coming under increasing pressure from third world governments (particularly after the failures of UNCTAD V in Manila), and being forced to be more conciliatory.

Given the uncertainties that still remain, delegates leaving New York expressed views ranging from "concerned pessimism" to "cautious optimism" about chances of a significant agreement on these issues being made in Vienna. Much will depend on what happens in the negotiations between now and the end of August. The Group of 77 is meeting in Bucharest to discuss its negotiating strategy at the conference and others are meeting elsewhere.

On one point, however, the secretariat had its way. On the first day of the conference, the initial proceedings will include a performance of Beethoven's Fidelio overture. Some had complained that this would be time-wasting; others that, as western music, it might not be appreciated. The secretariat has defended its choice by pointing to the music's radical theme — and after all, you can't go to Vienna without listening to music. □

news in brief

UK government scientists step up strikes: British scientists are calling a further series of half-day strikes and demonstrations in support of their pay claim of 36%-47%. The government has offered increases ranging between 15% and 24%. The Institution of Professional Civil Servants is calling out its 20,000 scientists, 40,000 technicians and 10,000 related staff in a series of Tuesday and Thursday actions that will last until 7 August. Government establishments at Southampton, Leeds, Bath, Reading, Newcastle, Birmingham, Bedford, Cardiff and Glasgow will be involved successively. "This campaign will stop everything in these localities", said an IPCS official. The half-day actions add to the small number of volunteer indefinite strikers who are seriously affecting the country's communications and power supplies. In addition, IPCS has announced withdrawal of "good will" from operations at the Ministry of Defence, Departments of Environment and Industry and the Atomic Energy Authority. Support for further action is strong among union members.

King's College principal says UK universities should be cut: Sir Richard Way, principal of Kings College, London University has called for a reconsideration of the number of universities in the UK. Speaking at the opening of the 150th anniversary exhibition of King's College, Sir Richard gave his support to government economies. "Your government has been elected to try to establish some control over public expenditure and this is an aim which I very strongly support. I don't personally believe that the university system as a whole is necessarily short of money." Sir Richard told *Nature* that university expansion in the last 15 years did not mean that the expansion should be defended. "Just because you have 45 universities doesn't mean that you need 45 universities" he said. "I am an advocate of pruning." But such a measure need not compromise the UK's research capability. "It would be desperately wrong to compromise research", he said.

Benn calls for UN energy organisation: Tony Benn, former Energy Secretary in the Labour Government, has called for the creation of a United Nations Energy Agency to help avoid "confrontational energy policies". Although OPEC has previously resisted this proposal because of their fears of price control, Benn feels that the world is slowly moving in that direction. The important thing is to bring OPEC, the West, the Communist countries (who export oil to the West) and the non-oil producing countries into an arena that can prevent confrontation, he said.

Speaking at the annual conference of the National Union of Mineworkers, Benn also called for a public debate on nuclear power development in the UK. Previous growth of nuclear power has been predicated on overall growth, he said. But with a forecast of negative UK growth and with the events of Harrisburg in mind, big nuclear plants, particularly pressurised water reactors, need full public discussion. "We need absolute satisfaction that expansion is necessary, that expansion must be nuclear and that leaks and waste disposal problems are solved before going ahead."

UK stand on whaling: The UK government will support the proposal for a moratorium on commercial whaling. Mr Alick Buchanan-Smith, Fishing Minister at the Ministry of Agriculture, Fisheries and Food, announced this on Monday at the opening of the 31st annual meeting of the International Whaling Commission. "Resumption of whaling", he said, "should only be reconsidered if evidence of recovery of stocks and improvements in the methods of killing justifies it." He also announced government proposal for immediate discussions with the European Community calling for a Community-wide ban on sperm whale imports. This greatly disappointed environmentalists who had expected the government to announce a ban at the meeting. Czech Conroy, for Friends of the Earth, said although they welcomed the government's support for a moratorium on commercial whaling, they found it "totally illogical and unsatisfactory" that sperm whale imports would continue to be allowed. "The proposed discussions between the government and our partners in the EEC to achieve a community-wide ban on sperm whale imports will permit thousands more whales to be killed." Friends of the Earth, he said, would continue to press the government "hard and fast" to follow up these discussions.

France opens new information centre: A new data centre, with the purpose of providing French scientists with bibliographic information produced by the world's major documentation services, was opened at Valbonne near Nice at the end of last month. The capacity of the computerised system will be 10^{10} bytes which will allow access on-line to about 10 million references.

The Centre was built in the record time of six months at the special request of Giscard d'Estaing, the French President. The authorities had been concerned about the rapid development of data banks in the US, UK and Germany, which according to Pierre Aigrain, Secretary of State for Research, could lead to French "cultural alienation". There was also concern that French research is not properly represented in foreign data banks. The official reason for the creation of the new centre, however, is economic. French scientists have been making about 60,000 inquiries to US data banks each year at a cost of 15 million FF.

— From the staff of La Recherche

Chinese synchrotron construction slows: China's 50 GeV/c alternate gradient proton synchrotron, originally planned for completion by 1982, will not be finished until 1985. the announcement appeared in the Beijing (Peking) People's Daily in an article by Zhao Dongwan, a vice-chair-person of the State Scientific and Technological Commission, who appears to be in charge of the administrative side of particle physics in China. He wrote that work is proceeding on schedule for the experimental centre housing the accelerator, but the target date of 1982 announced at last year's National Science Conference has been put back to 1985 because China's national economy is being adjusted. "This means a higher standard" Zhao emphasised. Zhao also stressed the need to continue the implementation of the principle of self-reliance. The basic approach he wrote would be to send people abroad to study advanced accelerator technology while designing and building the equipment at home. China should not import equipment that she herself could produce.

In the meantime the Sino-American Joint Committee on High Energy Physics held its first meeting in Beijing on 11-12 June. This joint committee is the first of a kind which came into being after the signing of the Scientific and Technological Agreements between China and the US earlier this year. The two-day meeting was jointly chaired by Professor Zhang Wenyu, director of the High Energy Institute under Academia Sinica and by Dr J.E. Leiss, associate director of the Office of Energy Research in Washington.

— From T.B. Tang

Education in Chile in decline: The long term educational policy of the Chilean junta aims to eliminate entirely universal education. In a statement made in March, President Pinochet stated that the government intends to reduce educational opportunities to ensure that no more than a handful of children, whose parents can afford it, go to secondary school. In 1978, less than 70% of all children received an education compared to 92% under the Allende government. The education budget has been reduced from 17% of the total to 13.5%. In addition, the administration of many schools has been given over to business consortia who hire the teachers and plan the curriculum. The consortia receive tax benefits for providing "resources for educational purposes". Operation of all schools from primary to university level is under the final authority of the Commando de Institutos Militares.

France puts science under the microscope

Pierre Aigrain talks about his first year as France's science minister, which has culminated in a blockbusting survey of the whole of French science. **Judy Redfearn** reports

AT THE END of last month, a report entitled "L'état des sciences et des techniques Francaises', was circulated to French scientists, administrators and politicians for their information and comments. A slim document, it is the summary of a study conducted by the Délégation Generale à la Récherche Scientifique et Technique and the Comité Consultatif de la Récherche Scientifique et Technique (*comité des sages)* under the auspices of the science minister, Pierre Aigrain. Two thicker tomes, one for physics and one for life sciences are to be published later. "As far as I know, it is the first time that any country or any government has tried to do a study of this kind", according to Pierre Aigrain.

Previous studies, he says, have compared the level of funding of a particular area of research in France with that of other countries. But "that's not what we have tried to do here". The aim has been to identify the strengths and weaknesses of each branch of research in France: to compare it internationally and assess its relevance to national economic and social objectives. "This is a critical study which is necessarily subjective. I expect that it is going to make us very unpopular". But it was felt necessary as a basis for formulating future science policies. The exercise is to be repeated annually, to begin with, and then at longer intervals as the methodology improves.

Good research, explained M. Aigrain, poses few problems. Even if it is not particularly relevant to national needs, provided that it is not too expensive, it should be supported and encouraged. Problems arise, however, "with sciences in which we are weak. There are those in which we are weak compared to the rest of the world and those in which we are weak but the rest of the world is no better". An example of the latter is human nutrition. France may be in the front row, but "that row is moving much too slowly compared to needs".

The greatest difficulties arise, however, when France lags well behind international competitors in a particular field. Sometimes the best decision will be to forget about those areas. But in some cases, a weakness can have "unfortunate, sometimes ctastrophic consequences", not only on that field but also on neighbouring ones. An example is clinical pharmacology which is important for good pharmaceutical research.

Pierre Aigrain, together with the DGRST and the *comité des sages*, is now faced with incorporating the main findings of the study into the eighth five year plan for 1980-85 and a ten-year research and development strategy, both currently under preparation. France has been running five year plans for science and technology since the end of the war: the idea is to plan fairly precisely in advance what research projects should be done during the next five years. The ten year strategy, however, is more of an attempt to formulate basic guidelines for government R&D "in a ten year perspective".

One problem the ten year strategy will address is that of providing enough jobs. After the expansion of the universities in the 1960s, France, like many industrialised countries, now faces the problem of continuing to provide work for young scientists. With only a modest growth in the real value of the science budget, it has had the choice of either freezing the number of posts available and providing each scientist with a good working budget, or increasing the number of posts and consequently reducing the money available for equipment and research. As the lesser of two evils,it has chosen the latter.

In 1975, the government decided to increase the number of research scientists employed in its laboratories by 3% per annum and to keep the level of the science budget in line with the average rate of government investment. "The rules for the next ten years will be of a similar kind, although more elaborate", says M. Aigrain.

"The training of scientists is a long term problem", he explained. "Not only does it take a long time to train them, it takes even longer to establish good training systems. We feel that although creating new jobs only makes our problem worse, from the point of view of the amount of money each scientist has to work with, it is a less serious problem and more easily reversible than the one we would have if we let the training systems die out".

A good budget could greatly improve the remaining problem. The 1980 budget, for example, is expected to be appreciably more than the one for this year. If it is, then the shortfall in funds per research worker could be remedied in "one or two years". A new training system, however, would take 15 years to establish "if we let the present one die out".

The 3% growth rate has by no means solved the jobs problem. The French universities system is suffering particularly badly from stagnation as a result of the earlier expansion — a situation made worse by the fact that very few scientists, even compared to most other countries, take jobs outside academia. "Our mobility rate is very low. If a greater proportion of scientists employed in government laboratories moved to other sectors, including research in private industry, we could have our cake and eat it: we could increase the means at the disposal of each scientist and at the same time maintain our training system".

Minister of Science, Aigrain: "it's a rather special sort of job."

Mobility, however, is a problem of psychology — not only of scientists but also of prospective employers. "You can't change behaviour by law — at least not in a democractic society. Actions can only be indirect". The indirect actions France is currently taking involve giving advantages to scientists who move into industry and their employers.

It is also trying to revamp an old system whereby scientists can be put on "detached duty" in industry for a few years. "Even this has not been as successful as we would have expected because while the scientists are on detached duty they have not been getting promotion from their government employers. This is something which we are going to try to change."

Moving research scientists into industry, however, not only benefits the universities and government research laboratories; it can also bring valuable expertise and new ideas to industry which badly needs more contacts of this type. "On the whole French science and technology is holding its own", according to M. Aigrain, "but the contacts between it and the people who can apply it are very poor. In my opinion, it is a matter of personal contacts, which are insufficiently developed."

The solution does not lie with creating more government labs for applied research, however. "I've been in industry in charge of R&D in a major company and I know that doing industrial research efficiently implies an industrial environment".

Knowing how best to act to stimulate

greater mobility of scientists or greater cross-fertilisation of ideas with industry, involves judgement of human behaviour and a bit of applied psychology. Psychology, however, is not one of the hard sciences, says Aigrain, who was initially trained as a solid state physicist. But since he became science minister one year ago it has assumed a greater role in his working life.

Aigrain came to the post after a varied career in both science and administration. As a young physicist he was appointed by General de Gaulle in 1958 to the newly created *comité de sages* (CCRST) — de Gaulle had wanted some young blood on the committee — and later through earlier connections as a naval officer, he was appointed head of an advisory committee concerned with defence research.

After a spell with responsibility for higher education and a five year term as head of the DGRST (1968-73), he moved into private industry to become general technical manager of Thomson. "I had planned that the rest of my active life would be spent as general technical manager of an industrial company. I have never been involved in active politics, so it was a very great surprise to me when the Prime Minister, Raymond Barre, asked me to enter the government in April 1978."

Pierre Aigrain is one of a handful of French ministers who have never run for election. Another is André Giraud, the industry minister, under whose department science and technology officially come. The job of the science minister, however, is unique in the French government.

"I operate by delegation from the Prime Minister on inter-ministerial matters. My work mostly involves coordination, strategy, planning and budgeting of civilian R&D in all ministerial departments. This is a rather different job from that of a minister who has to run a department. What I have to do is convince my colleagues or the Prime Minister of what should be done in matters of science and technology. It's a rather special sort of job." The DGRST is directly under his responsibility. "DGRST is really my operating cabinet and my means of action."

Determining the science budget, and how it should be spent, is Pierre Aigrain's major task. France currently spends about 1.8% of its gross national product on R&D. Ten years ago, the figure used to be 2.1%; 20 years ago it was well below 1%. In spite of the decrease in this percentage over the past ten years, the volume of research has increased very slightly because of the modest growth in GNP.

On the whole, M. Aigrain believes that the French government is sympathetic to the needs of science and technology. His main problem with parliament, however, is to explain "why, with the budget we have, we should put money on this and that and not necessarily on some of the ideas which are in the news — which may not be the best, or which anyway, cannot be efficient unless we also maintain a sufficient amount of basic research."

He agrees that parliament could be much better informed. A group of MPs, known as Intergroup, used to meet regularly to discuss science policy issues, but with the pressure of seemingly more urgent commitments, this has lapsed and there is now no equivalent of the UK select committee structure wherebvy MPs can gather the opinion of scientists at the grass roots. Something along these lines would be "very useful", however. Scientists "have a duty to try to explain to politicians what the problems of science are, not in party political, but in science policy terms: down to earth terms".

For one reason or another, France has missed out on many of the debates around science policy issues which have aroused public interest in recent years in other industralised countries. In the case of nuclear energy, Pierre Aigrain thinks that the French people recognise that their country, having very few energy resources of its own, is in a particularly difficult position. "There may be many Frenchmen who don't like nuclear energy", he says, "but there are few who doubt that it is necessary".

In the case of genetic engineering, the French public recognised early on, the confusion surrounding the debate in other countries, where concern had centred on the possibility that "some experimentation could be dangerous for the people doing it or the immediate surroundings" and "the vague fear" that genetic engineering could lead to "ethically unacceptable" experiments. "In France I think it was clear from the start that these were two different problems. The problems of the dangers could obviously be handled provided that scientists took the right precautions. People are, I think rightly satisfied that we can handle this problem because we have been handling a much more difficult one for tens of years," – namely the production of large quantities of vaccine from live virus.

About health and safety generally, and concern over carcinogens and toxic substances, M Aigrain says that there are worries in France, but that "up until now, Frenchmen have been a little more rational and a little less emotional. We in France have a big drawback. We tend to have too much of an analytical mind — we are too rationalistic, too Cartesian. In research this is not necessarily an advantage because, in order to be creative, researchers have to be a lot more pragmatic. But it does have the advantage that even the average Frenchman can realise relatively easily that a debate is created on a non-logical basis". □

What the report says about French science

TEN thousand people, of whom 4,500 are qualified scientists, are employed in fundamental physics research in France. The budget for paying their salaries and buying equipment for their work is about 1.7m FF per year. A further 3,500 researchers are employed in physics for engineering.

The DGRST study found French fundamental physics rather healthy, especially in the fields of high energy physics (where France has a reputation for building bubble chambers), nuclear physics, thermonuclear fusion and solid state physics. (The latter is an example of a fundamental branch of research which has good links with industry.) Gravitation, cosmic rays and molecular physics are weak, however.

In applied physics, says the report, the results of research in optics and fluid mechanics are finding their way into industry, but those in solid mechanics and materials sciences are not. The quality of research, for example, in materials sciences is good, but it is unevenly distributed amongst sub-fields and is too academic to be well tuned to the needs of industry. Chemical research done in universities and government laboratories, however, has close links with the chemical industry, but there is need for even greater collaboration. In quantum chemistry, radiochemistry, nuclear chemistry and catalysis (with the exception of catalysis by enzymes) collaboration is good; but it is poor in electrochemistry and chemical engineering. Much of the research is very dispersed and there is a need for some regrouping.

About 4,500 full-time and 6,000 part-time scientists are employed in life sciences research. Areas of which France is particularly proud include cellular and molecular biology, endocrinology, applied immunology and and reproduction and development. Over the past seven years, the programme in the latter has led to a reduction in perinatal death from 23.4 to 16 per thousand. Bacteriology and human nutrition, however, are very weak and neurobiology is currently being 'rejuvenated'.

In energy research, a field with important social and economic implications, the report says that France is doing well in nuclear energy and solar power. It is going ahead in 1982 with plans to start building light water reactors under licence from Westinghouse and with the construction of its demonstration commercial fast breeder reactor, Superphenix. In renewable energy research, it is putting most of its efforts on solar energy and in the long term, thermonuclear fusion. Research on fossil fuels is strong when it comes to prospecting for off-shore for oil (France is well renowned for off-shore technology because of its efforts in this area) but weak when it comes to coal research.

Will China be tainted by western science?

CHINESE science is treading a careful tightrope between its long-term aspiration of a specifically Chinese-orientated scientific outlook and the short-term expediency of importing western ideas wholesale. Recent statements have indicated that although the ideal is still to the forefront of Chinese scientists' minds, it is perhaps being undermined by the very scientific exchanges essential to the modernisation of Chinese science.

The influx of western ideas into the physical sciences pertains to science itself as well as to its social dimension, which includes the administration, funding and general management of science and technology. In the past few months, some ministers and many scientific groups from China have toured scientific institutions in the west, and a large number of western scientific teams are returning the visits. The first impressions apparent in the media were that the Chinese showed great interest in western practice. An example is that after the visit of the State Scientific and Technological Commission delegation to Japan last December, articles appeared discussing the merits of such institutions as the patent system which were introduced into Japan when it became westernised. In fact, however, the Chinese attitude is a cautious one. Commentaries in the party paper on 19 April and 8 May, for instance, stressed that while China is learning advanced science and technology from abroad, it will on no account blindly import social practices; future science policy will be firmly China-based.

On the other hand, in looking towards the future, the Chinese realise that their present system of science management is not perfect. They freely admit, among other things, that their national research efforts are plagued by wasteful duplications as well as damaging omissions — perhaps surprising in view of their central planning. It seems that the misguided motivation of some scientists, together wiht insufficiently democratic coordination between parallel funding offices, are the major factors. Some institutes have recently adopted the practice that individual contribution is judged mainly by the authorship of papers, but such professionalism can sometimes lead to researchers doing only publishable and prestige-promising work. The Chinese believe that the problem of rationalising the organisation of science and the decision-making processes will be solved by the inventiveness of the masses, rather than by imitating another country, no matter how advanced its science. Thus, many of the systems created and evolved in China during the last twelve years are likely to be kept, forming as they do a useful basis for improvement. During this period the achievements of Chinese science have been satisfactory, when compared to the resources available; last year, according to preliminary statistics, more than 12,000 research projects were successfully completed.

This attitude, that a specifically Chinese science can build on a firm past basis, is reiterated in a report on 10 April in the *Guangming Daily* of a meeting of Beijing University professors. The speakers, among them several leading scientists, asserted that as developments from foreign countries are incorporated into the Chinese social system, Chinese science must retain its original character. To us, its outstanding features include an emphasis on combining both traditional and modern knowledge, on linking laboratory investigations with production in the field or factory, on collective rather than individual efforts and rewards, and on the participation of the masses in both the direction and the conduct of research. It is relevant in this context to note that China continues to devote considerable resources to the popularisation of science: it is setting up four additional specialised studios to cater for the rising demand for science and educational films, a demand at present partly satisfied by dubbing films purchased abroad. In the meeting, some professors also argued that political education should be emphasised in the training of young scientists.

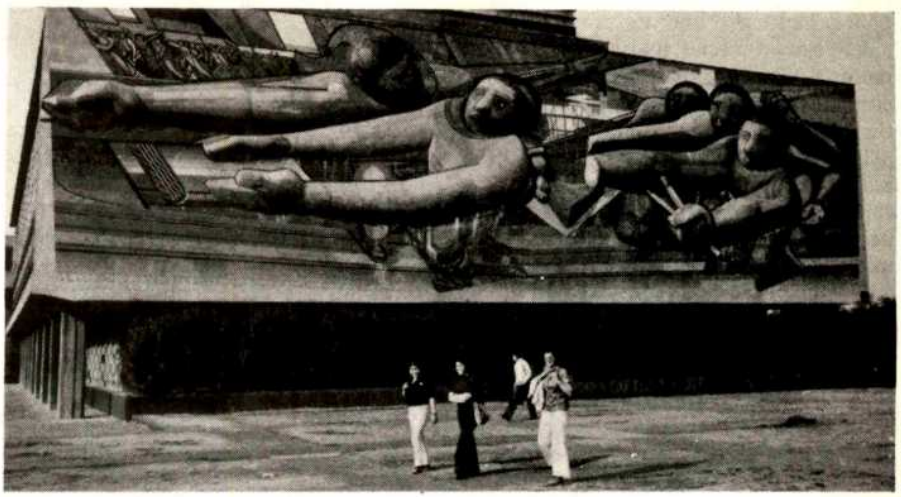
For China, at present, the provision of scientific and technological manpower holds the key to the 'fourth modernisation' (*Nature* 19 April, p. 682). A concrete expression of this situation is that instruments such as electron microscopes — if they were foreign imports — are often under-used due to inadequate experimental skill or lack of maintenance.

According to a 1977 report from the Organisation for Economic Co-operation and Development in Paris, there were then some 335,000 scientists and 725,000 technicians working in China (excluding personnel engaged in medical research). At the National Science Conference convened in March 1978, the goal was set that by 1985 an army of 800,000 scientific workers will be formed, double the present number. Chinese universities took in a total of nearly 400,000 new students last year, and to help its educational targets China announced last August that it also plans to send some 10,000 students to the US, the UK, France, Germany and Japan. This year about 500 are going to the States, 200 to England, and 100 undergraduates have already arrived in France.

Although western visitors may import foreign ideas into China, the real danger to the concept of a long-term Chinese-orientated science lies in the return of these many young people after exposure to western scientific culture (although the flow in the opposite direction may also be interesting). This trend will be exacerbated by closer links between students in China and their counterparts abroad.

At present there is a dynamic balance between the ideal of an indigenous Chinese scientific culture and the influence of established western scientific ideas; only in the next five years, as these influences are absorbed, will the future pattern of the world's largest new scientific force become apparent.

T.B. Tang



The world's first giant panda born by artificial insemination made its debut at Peking Zoo recently. The panda, named Yuan Jing — meaning "First Crystal" — was born last September weighing only 120 grams. Yuan Jing has aroused interest around the world because of renewed hopes for the famous but uncooperative panda pairs at London Zoo and Washington Zoo. All previous attempts to mate the pairs have failed, including flying in other pandas from the Soviet Union and China. China is the only country so far to have bred pandas successfully in captivity. Baby Yuan Jing started to walk at three months, developed the familiar black and white hair at five and was weaned at seven months.

Mexico: slow fight against impossible odds

By John Hutton

Universidad Nacional Autonoma de Mexico: increasing demand for education

MEXICO City is one of the largest and fastest growing cities in the world. The colonial heart, built upon the remains of the Aztec capital, is beginning to atrophy as the periphery expands. The volcanic peaks which crown the valley are often hidden in the smog produced by industry and by the ageing vehicles which edge bumper-to-bumper down the arterial thoroughfares designed for a city of a smaller size.

The provision of services cannot cope with the influx of population. There is a chronic housing shortage and, in many parts, scanty supplies of water and electricity are further burdened by illegal tapping. Yet, every day, thousands of people pour into the city. They come to establish themselves in the ranks of power, to enter business, to seek higher education, to find jobs in the factories or to work as household servants.

Mexico City's population of about 13 million is expected to reach 30 million by the turn of the century, and its current rate of growth, the nation's population should exceed that of the USA in fifty years. While 30% of Mexicans enjoy incomes comparable to those in the developed world, more than 50% know the realities of underdevelopment.

Malnutrition is widespread, as is chronic respiratory and gastro-intestinal disease. Life expectancy is about 65 years but infant mortality is estimated at 66 per thousand live births, more than twice that of Cuba and four to five times that of the USA. More than half the population receive no more than a few years schooling and illiteracy stands at 25%. In recent years, the domestic production of foodstuffs has not sufficed and staples, including corn, have had to be imported.

In confronting these problems Mexico can call upon a stable political system, a diversified economy, the vision of its administrators and, in recent years, its vast reserves of petroleum.

In accordance with the spirit of her constitution, Mexico sees the key to development as lying in investment in education and in the construction of an economy with an indigenous base rather than one which relies on imported technologies. In keeping with these plans, investment in research and scientific education has burgeoned in the past ten years. And there now exist pockets of activity which, though not yet mature, are well on the way to manifesting a style which is both in line with the country's aspirations to knowledge and relevant to its material needs.

The body largely responsible for the implementation of this policy has been the 'Consejo Nacional de Ciencia y Technologia' (CONACYT) which was established in 1971 during the presidency of Luis Echeverria. In 1960 Mexico could boast only 385 qualified investigators which, given its rate of demographic growth and the scientific boom in the West, was little advance upon the 30 or so registered in 1929. By a system of grants and scholarships CONACYT brought that number up to 13,300 by 1978. And in the 1978-1982 period a further 17,000 scholarships will be awarded, most of which will be for postgraduate research within the country.

The pattern of the scholarship distribution reflects the priorities of the planners: 17% to studies on the use of energy resources, 13% to agronomy and forestry, 13% to basic research, 11% to nutrition and health, 9% to social development, 7% to fishing, 7% to construction and transport, and 2% to public administration.

This is a far cry from the climate of the 1950s and early 1960s when the glamour of imported technology held sway. In an era often described as 'anti-science' or 'anti-development', overseas-based corporations were given preference in the construction of manufacturing industries; in the field of agriculture the US-inspired 'green revolution' was promulgated; and even in the petroleum industry, nationalised since 1938, much of the geological data concerning the country's resources lay in foreign hands.

Movement away from this ethos gathered impetus in 1961 when the 'Instituto Mexicano del Petroleo' was set up. Apart from direct benefits to the industry, this initiative helped encourage the return of scientists from overseas. By the same token, it provided ammunition for those who wished to draw attention to the dearth of scientists within the country and the need for an adequate training scheme. Meanwhile, in the universities there was a mounting realisation that the nature of the social system had to be changed, a movement which culminated bloodily in the student riots of 1968.

Cries for reform were heeded by the incoming president. In 1970 Echeverria made the unprecedented move of increasing spending on education from 1.8% to 3.1% of the Gross National Product (GNP). At the primary school level the text books were re-written with an emphasis on authentic growth. Science education was begun at the age of six and broadened to include such sensitive issues as human sexuality, a move which required presidential sanction and which met with fierce opposition from conservative sectors of the press and television. The CONACYT scholarship plan was instigated at this time, and spending on research radically increased, from 0.1% of the GNP in 1970 to 0.6% by 1978; it should reach 1.0% by 1982.

During the 1970-1978 period, a policy of support for basic research has evolved. The rationale has been that work of an applied nature would flow more soundly from a solid foundation of scientific principles, and that experience in basic research is essential to the attainment of a 'critical mass' of research facilities and expertise.

The pursuit of such a policy seems to have paid off, as indicated by the emergence of a new type of scientist: one whose work habits are geared to productivity, one who is open to new ideas rather than dedicated to perpetuating dogma, one who demands the critical participation of his students rather than their unswerving loyalty.

It will take time, however, before the new ventures in science make their full impact upon the economic and social development of the country. The successes attained so far have sometimes been marred by the difficulties of realising the economic potential of a discovery. As Dr Arturo Gomez-Pompa, director of the 'Instituto Nacional de Investigacion sobre Recursos Bioticos', put it: "the economic potential of a chemical with interesting

The author visited Mexico on a Nature *travelling fellowship.*

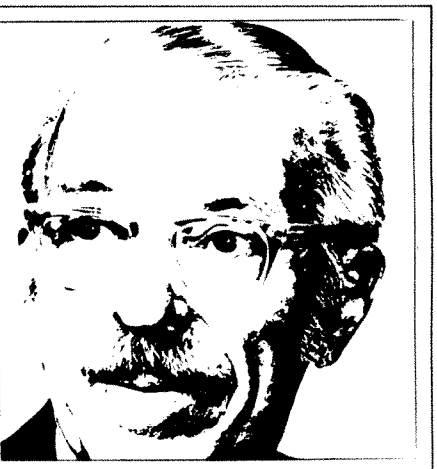
©Macmillan Journals Ltd 1979

pharmaceutical properties, extracted from a native plant species, may be lost when the material falls into the hands of a foreign concern which modifies it, patents it and then markets the new compound".

Several ambitious attempts have been made to grapple with this problem, within the framework of a move towards decentralisation. In Tonanzincla a church in the style of Indian baroque, open fields and eucalyptus trees provide an idyllic setting for the 'Instituto Nacional del Astrophysica, Optica y Electronica'. Known in the village as the 'observatory', this once prestigious centre of astrophysical research is now a base for investigation into optics and electronics. Basic research is undertaken by the fifteen or so staff and by the fifty-odd students who are studying for higher degrees.

Alongside the laboratories a pilot factory has been constructed for the manufacture of microscope lenses. Grants are awarded to enable young people from the village to work on the production line.

At the University of Puebla technical expertise in the construction of micro-circuitry is also being developed for research and teaching purposes, in addition to its contribution to the nation's needs. As at Tonanzincla much of the equipment is manufactured at source.



In the State of Durango, the government has set aside a large tract of land representative of the eco-system of the region. This 'biosphere' is designed not only to preserve the genetic diversity of plant and animal species in the region but to provide a laboratory in which experimentation into more rational forms of land use can be made. This project is being conducted in collaboration with the local farmers of the area.

None of these achievements have been gained easily. The constitutional policy of a six year non-renewable presidency brings with it administrative re-shuffling and consequent re-formulation of plans. The scientist, like anyone else, has little guarantee of continuity in his work. Time must be invested in convincing each new administration of the validity of his ideas, either through the cultivation of friends in power or through the publication of his work in a form amenable to the layman. Good though this may be for the purposes of public debate it consumes much of the energy of the successful man.

The scientist must also face the problems of the nation as a whole. He must be able to cope not only with present-day realities but with the contingencies which emerge as the population increases in numbers, literacy, and as more than ever move towards the city. Can the 'Universidad Nacional Autonoma de Mexico', for example, with 150,000 students already, accommodate the increasing demand for higher education without sacrificing teaching standards? Many see it as the race against time.

The scientist, it is hoped, will be instrumental in finding alternatives to mitigate the flood of people reaching the city, people who, each in their vague search for opportunities, constitute a major flight from reality when considered within the nation as a whole. The heroes of Mexican folklore are not Cortes and his men but Quauhtemoc, Father Hidalgo and Emiliano Zapata, men who dared confront the established order against impossible odds. The resourcefulness of the Mexican scientist in achieving what he has in the last ten years shows that such a spirit is still alive. Will it suffice for the coming era? □

All at sea

Thomas H. Jukes

THE muscular American was ahead of me at the cashier's desk in the hotel at Delhi on 3 June. He was arguing forcefully about charges on his bill for more than the actual number of local telephone calls that he said he had made. This auditing impressed me as being unusually precise, but perhaps, I thought, he is a professional accountant. The hotel won a computerized victory, because the local calls were metered to each room.

A few minutes later, I stood beside him in the front entrance to leave for the airport, and I noticed that his luggage was tagged "Agency for International Development". Spontaneously, I spoke to him; I said that I was interested in the public health work of AID, especially in malaria. He said that his was a different field, that of disaster relief. He invited me to ride to the airport, in his officially-provided car, where we would take the same flight, I to Bangalore, but he to an earlier stop, Hyderabad. He had to organize relief for victims of the 11 May cyclone that had devastated a large area in Andhra Pradesh.

I asked him what he had done lately, and he said he had recently been to Yugoslavia to help the survivors of an earthquake. He then launched a discussion of rehabilitation, how, for example, it was better that an Indian farmer receive a live replacement for a dead bullock rather than a gift of food. A variant, I thought, of the old adage about helping a starving man to catch fish.

George Beauchamp was my companion's name, and obviously he was used to taking charge. He deftly piloted me through the churning crowds that pack Indian airports and through the check-points to the departure area. We boarded the air-bus and went to our separate seat assignments after bidding each other goodbye.

As I sat in the plane, I suddenly realized what George Beauchamp must really be like. The surface that he had shown to me was that of a brisk, efficient and business-like public employee, arguing about his bill, and carefully attending to other details of the day. Impulsively, I got out of my seat, and went to find him. "George", I said, "I wish you all future success in your great work for humanity".

He thanked me, and then poured out his indignation at the current treatment of Vietnamese refugees, adrift on a hopeless sea, rejected at all attempts to land. He said that a few years ago he had assured people in Vietnam, in answer to their doubts, that the President of the United States would not let them down. "And now," I replied, "the Americans have forgotten the poem by Emma Lazarus". In answer, he passed me the book he was reading: It was the historical account of the ship that carried doomed and despairing refugees from Hitler from port to port, and finally back to extermination in the gas-chambers of Germany. George pointed to a verse on the front page; there were the wellknown lines I had just quoted to him:

"Give me your tired, your poor,
Your huddled masses, yearning to breathe free,
The wretched refuse of your teeming shore
Send these, the homeless, tempest-tossed to me."

But who will light, once again, the lamp beside the golden door for the despairing waifs from Vietnam? It has been predicted that one of each two will die by drowning. There is a ray of practical idealism in the darkness: a Hong Kong official has pointed out that it may be possible to turn the Vietnamese refugees "into productive labour to support our economic growth. But we must obtain a commitment from other nations to absorb the human wave...".

Will America respond? Numerous among those who make decisions for her to-day are the upwardly-mobile descendants of the "huddled masses" whom Emma Lazarus apostrophized. Have they forgotten the obligations of their heritage? □

news and views

Peptides in profusion

from John S. Kelly

IN the coming year at least nine major international meetings are being devoted to the peptides present within neural tissue. The first * was a massive affair: for three days, an audience of at least 700 from all over Europe and North America listened to 28 invited speakers. Almost half the speakers devoted their attention to methodology and described how they had used their own particular skills to investigate one or more of these peptides. The others had clearly been instructed to concentrate on one peptide studied with a great variety of techniques, with only one of which they were acknowledged to be expert. By and large these speakers had been selected from the viewpoint that peptides form a new class of neuroactive substances to which certain generalities apply. For instance, peptides may fall into defined groups, each being derived by cleavage from a large precursor molecule. There also seemed to be support for the idea that peptides released from nerve terminals will in general not only mimic the actions of more conventional transmitters such as amino acids, acetylcholine and catecholamines, but that any new unexplained results are suggestive evidence that peptides may mediate their actions on the postsynaptic cell in novel, unconventional ways.

Since much of the work presented has already been published and will in any event be brought together in the proceedings, I shall draw attention here to some of the novel work mentioned only at the meeting and which I feel may prove to constitute the highlights of 1979.

Identification

In the methods section R. Elde (University of Minnesota, Minneapolis) drew attention to difficulties that have delayed the identification of peptide-containing elements at the electron microscopic level. Although he did not discuss methods based on the use of horseradish peroxidase to identify nerve terminals containing immunoreactivity, it is clear that this type of work is still hampered by the compromises needed to preserve the antigenicity of the peptide-containing tissue. Frequently the concentrations of aldehyde fixatives that are tolerated are too low to ensure the integrity of tissue ultrastructure. It therefore seems that although the reaction product in the horseradish peroxidase method is easy to identify at the electron microscopic level, the thin frozen sections which appear ideal for light microscopy are rarely adequate for ultrastructural studies. However, even in these studies, where the reaction product is in the terminals and in apparent association with synaptic vesicles or the presynaptic membrane, this may simply reflect the sites with which aldehydes react most readily. To overcome some of these difficulties Coulter and Elde (*J. Histochem. Cytochem.* in the press) have developed a method based on ultrathin serial sections cut from epoxy-resin-embedded material and the preparation of alternate sections for conventional immunofluorescence and electron microscopy. Although the resolution of the material is highly dependent on the thickness of the sections, single areas of fluorescence 0.2 μm in diameter can be recognised on photomicrographs enlarged to 8,500 times magnification and then identified on the corresponding electron micrographs. Many of the small fluorescent areas can be identified as synaptic vesicles. Coulter and Elde have yet to explore the possibility that post-embedding staining of serial sections will facilitate the localisation of a range of different peptides in adjacent or even the same ultrastructural element.

LHRH release explains enigma

In his review of the neurophysiological status of peptides, J. L. Barker (National Institute of Neurological and Communicative Disease and Stroke) drew attention to the findings of Jans and Kuffler *Proc. natn. Acad. Sci. U.S.A.* **76,** 1501; 1979), which suggested that the release of luteinising-hormone releasing hormone (LHRH) from nerve endings in the frog sympathetic ganglion might explain the enigma of the non-cholinergic, non-aminergic 'late slow e.p.s.p.' first described by Nishi and Koketsu *J. Neurophysiol.* **31,** 109; 1968). This late slow e.p.s.p. lasts for 5 min and is found in both the large B cells and the small C cells. Although substance P, neurotensin, bombesin, somatostatin, thyrotropin-releasing hormone and angiotensin I and II concentrations up to 0.1 mM had no effect, LHRH produced a slow depolarisation of the ganglion incubated in 1 μM dihydro-B-erythroidine and 0.1 μM atropine. The effect was reversible and the depolarisation evoked by 20 μM amounts occluded the nerve-evoked 'late slow response'. Similar depolarisations were evoked by smaller amounts (0.01 μM) of the more potent LHRH analogues (D-Ala^6,) LHRH and ethylamide (D-Trp^6, Pro^9) LHRH. The effect of these analogues was not blocked by the removal of Ca^{2+} from and the addition of Mg^{2+} to the media in concentrations that blocked synaptic transmission through the ganglia. Unpublished work shows both the peptide and nerve-evoked responses to be blocked by LHRH antagonists.

The presence of an LHRH-like substance in the lumbar chain of sympathetic ganglia has also been confirmed by radioimmunoassay using the highly specific antisera developed by Nett and colleagues (*J. clin. endocr. Metab.* **36,** 880; 1973).

Degeneration studies show the LHRH-like material to be confined to the spinal nerves that contain the axons which initiate the late slow e.p.s.p. . LHRH-like material is also present in perfusates of the ganglia made with isotonic KCl and the release seems to be calcium dependent. This discovery of LHRH-mediated potentials in the frog sympathetic ganglion draws attention to the possible role of peptides in transmission in the peripheral nervous system. Substance P and enkephalins are now well established as potent transmitters in the guinea pig myenteric plexus and there is still a number of non-cholinergic, non-adrenergic synaptic potentials to be investigated.

Cholecystokinin

Both J.W. Phillis (College of Medicine, Saskatchewan) and S.H. Snyder (Johns Hopkins University School of Medicine, Baltimore) drew attention to their work which shows fragments of cholecystokinin to have potent actions in the frog spinal cord (Phillis & Kirkpatrick *Can J. Physiol. Pharmac.* in the press) and to be located in specific sites throughout the central nervous system (Innis, Correa, Uhl, Schneider & Snyder *Proc. natn. Acad. Sci. U.S.A.* **76,** 521; 1979). Earlier, Rehfeld and his associates (Larsson & Rehfeld *Brain Res.* **165,** 201; 1979) showed the biologically active octapeptide of cholecystokinin to be located throughout

*A symposium on The Role of Peptides in Neural Function was held on 7–9 May at the National Institutes of Health, Bethesda, Maryland. It was sponsored by the Intramural Program of the National Institute of Neurological and Communicative Disorders and Stroke, and organised by J. L. Barker and T. G. Smith, who will edit the proceedings which will be published by Dekker.

J. S. Kelly is a senior member of the scientific staff of the MRC Neurochemical Pharmacology Unit, Cambridge, appointed Professor of Pharmacology at St. George's Hospital Medical School, London from 1 July 1979.

© Macmillan Journals Ltd 1979

the central nervous system. Within the spinal cord its localisation in the substantia gelatinosa is reminiscent of the distribution of substance P in fibres thought to be involved in nocioception. Furthermore, they have demonstrated similar immunoreactivity throughout the autonomic nerves and ganglia of the gut and have a considerable amount of biochemical evidence to suggest that the neurotransmitter released from these nerves is the terminal tetrapeptide common to cholecystokinin and gastrin (Trp-Met-Asp-Phe-NH_2). On the isolated perfused porcine pancreas, Rehfeld and colleagues have shown the tetrapeptide to be a highly potent and specific releaser of insulin, glucagon, somatostatin and pancreatic polypeptide and suggest that the tetrapeptide may be the neurotransmitter of the nerves which innervate the pancreatic islet cells. Dodd and Kelly *(Proc. Physiol. Soc.;* 1979) have confirmed and extended Phillis's suggestion, that the action of cholecystokinin on central neurones is excitatory, by showing that both the octapeptide and tetrapeptide fragments of cholecystokinin excite rat hippocampal neurones.

Retinal peptides

In his review of somatostatin as a neuroactive peptide, J.B. Martin (Harvard Medical School, Boston), drew attention to his work with Rorstad and Brownstein (*Proc. natn. Acad. Sci. U.S.A.* in the press), in which they demonstrate the presence of radioimmunoassayable and bioassayable somatostatin-like material in acid extracts of the retina by using the release of growth hormone from dispersed rat anterior pituitary cells in culture as their assay. Gel-filtration chromatography confirmed that 96% of the material from the retina could be eluted as a single peak identified by the addition of synthetic somatostatin to the system. Increased levels of somatostatin were found in the retina of rats with hereditary degeneration of the photoreceptor cells and in rats in which transection of the optic nerve one year earlier had led not only to complete atrophy of the optic nerves but also to degeneration of the ganglion cells. The somatostatin therefore seems to originate within the retina. This work is complementary to that of Marshak and colleages (Marshak, Yamada, Basinger, Walsh & Stell *Invest. Ophthalmol. vis. Sci., ARVO Abstr. No.25,85; 1979),* who have used similar techniques to demonstrate the presence of somatostatin-like immunoreactivity in extracts of the frog, rat and goldfish retina. They have extended this work on 10 μm cryostatic sections of the goldfish retina by using a conventional immunofluorescence method to show immunoreactivity in two types of amacrine cells and one type of ganglion cell. The processes of the cells ramify in the most distal and most proximal sublaminae of the inner plexiform layer.

A more extensive examination of the localisation of distinctive populations of various peptide-containing amacrine cells in the retina by Brecha, Karten and Laverack (*Proc. natn. Acad. Sci. U.S.A.* in the press) was not, however, mentioned at the meeting. Brecha *et al.* have shown enkephalin-like, substance P-like and neurotensin-like immunoreactivity in the avian retina to be localised in separate subpopulations of amacrine cells with processes that arborise in quite different regions of the inner plexiform layer. The distribution of amacrine cells containing enkephalin-like material is quite regular, with the greatest density in the central region where they are spaced at approximately 40-μm intervals. Enkephalin-like reactivity is also a feature of the amacrine cells of the turtle. Subpopulations of amacrine cells containing substance P-like reactivity are found in the retina of frogs, toads, rats and rabbits.

The presence but not the location of a Met-enkephalin-like material in the avian retina was earlier demonstrated by Humbert, Pradellos, Gros and Dray (*Neurosci. Lett.* **12**, 259; 1979) using highly specific radioimmunoassays in conjunction with high pressure liquid chromatography and gel filtration. Earlier, other workers reported the presence of thyrotropin-releasing hormone-like immunoreactivity in the rat retina (Schaffer *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 579; 1977) and showed the levels of this material to differ in the light and dark. One hopes that these new studies which show subpopulations of amacrine cells to contain at least five different peptides will go some way to elucidating the function of the 15 different types of amacrine cell which Cajal identified in the retina.

The discovery of a possible LHRH pathway in frog sympathetic ganglia, cholecystokinin pathways in the nerves to the islet cells of the pancreas and possibly the spinal cord and the presence of various peptides in the amacrine cells of the retina surely must lead to the conclusion that the peptides in the brain behave no differently from the other substances already thought to be established as neurotransmitters in the central nervous system. □

Atmospheric arsenic

from Peter Brimblecombe

ARSENIC is toxic. This much at least seems to have been known for a long time. Its environmental chemistry is intriguing, because not only does it occur in various oxidation states, but it is converted to volatile compounds by methylation in reducing sediments in much the same way as mercury. The toxicity and mobility of arsenic have made it the subject of many studies in specific ecosystems, but Walsh, Duce and Fasching have discussed the global cycle of the element in a recent issue of the *Journal of Geophysical Research* (**84**, 1710, 1719; 1979). Their two papers on tropospheric arsenic reflect an increased concern that anthropogenic emissions are significantly altering the distribution of trace elements in the environment.

Man's influence on the levels of airborne arsenic has been a matter of concern since the seventeenth century when John Evelyn wrote hopefully in his diary that the charring of London's coal would remove its 'arsenic malignity'. Salmon and his group at Harwell in a more recent study (*Sci. Total Env.* **9**, 161; 1978) have also implicated coal smoke in the elevation of the arsenic concentrations in the air over rural England. They have examined the long term trends in atmospheric trace elements at Chilton in Oxfordshire, through the use of airborne dust samples collected on filters between 1954 and 1974. The arsenic levels commenced at about 8 ng m^{-3} in the late 1950s and declined to slightly less than 5 ng m^{-3} by the early 1970s. These closely follow the concentrations of smoke in the atmosphere, both in the gradual decrease, and the seasonal pattern of high levels in winter and low values in the summer.

There are good reasons for such a correlation. Arsenic is present in coal at levels of about 25 p.p.m. and almost all of this is released during combustion. Of the toxic elements lead, thallium, cadmium and selenium, only lead is found at levels as high as that of arsenic in fly ash. Like these other low boiling point elements, arsenic concentrates preferentially on the smaller sized particles by vapour transport within the furnace. Goldberg has extended this notion to ambient temperatures, arguing that the relatively high amounts of these elements in the atmosphere might well be explained by evaporation from rocks (*Geochem. J.* **12**, 75; 1978) although in the absence of amplification mechanisms this contribution is probably insignificant.

The concentration of arsenic in rural air over England appears to be a few ng m^{-3}, while concentrations determined in remote areas are somewhat lower. (Table 1). The enrichment factors relative to crustal elements range between 23 and 1,940 with a geometric mean of 313. This is largely due to the fact that the arsenic is found associated with sub-micron particles in which the crustal reference

Peter Brimblecombe is in the School of Environmental Sciences, University of East Anglia.

elements are depleted. The association with the small particle fraction hints at a vapour phase origin.

Walsh and his colleagues were at pains to distinguish between particulate and vapour phase arsenic (that is, < 0.05 μm). With the exception of some unusual events vapour phase arsenic accounted for only a few per cent of the atmospheric concentrations. This is to be expected as compounds with vapour pressures less than 10^{-11} atm are predominantly associated with particulates; the aerobically stable arsenic trioxide has a vapour pressure of only 6×10^{-12} atm. although they note that the ratio of particulate to vapour phase was inversely related to air temperature. In spite of the low concentrations of arsenic in the vapour phase it is important to remember that such low concentrations may reflect a species with a relatively short lifetime, but one which could be of considerable importance in distributing arsenic among the smallest aerosol particles.

The estimation of emission rates on a global scale is difficult because even where measurements are available the particle size is usually unknown. Natural sources are often even more difficult to evaluate because of the extremely low levels of arsenic involved. The largest natural source would appear to be volcanic (Fig. 1), but it is obvious that this could be subject to wide variations. Wind blown dust and particles from forest fires may both make contributions to atmospheric arsenic. The sea is an emitter and here volatilisation of the small amounts of naturally occurring methyl arsenic compounds may be significant. Biological sources account for about 3%, but even subtle changes in the assumptions about the release of particulates from plants and the methylation of arsenic compounds by bacteria could significantly change the importance of this contribution.

The construction of a global budget for arsenic emphasises the relatively large anthropogenic inputs to the troposphere. The principal use of arsenic is in the manufacture of agrochemicals; arsenic compounds have had a long history of use as insecticides, but during the past 20 years there has been a change from the use of inorganic to organic arsenicals, which can be applied at a much lower rate. There has also been a marked reduction in its use in insecticides, so that it has become largely restricted to herbicidal compounds. Good evidence for these changes are to be seen in the consumption of arsenic in the United States which halved between 1950 and 1970.

The largest man made contribution to the atmosphere arises from releases incurred in the manufacture of metals, as arsenic is frequently associated with ores. The largest emissions occur in the production of copper. Combustion of fuels is an important source, but coal is really the only fuel of significance, with the incineration of waste making an important contribution. The input from agricultural sources and processes such as cotton ginning is of about the same magnitude as the combustion source. the importance of these anthropogenic sources and the low emission rates from the oceans means that higher levels of arsenic are to be expected in the air over the northern hemisphere. The rates of input seem in reasonable agreement with the measured rates of removal. The tropospheric residence time determined from these rates and the atmospheric arsenic burden suggest a residence time of about 9 days, which is about that which would be expected for a tropospheric aerosol. □

Anomalous H-2 antigens on tumour cells

from Kirsten Fischer Lindahl

FOUR years ago the idea was discussed (*News and Views* **254**, 653; **256**, 7; 1975) that some tumour-specific transplantation antigens (TSTA) were anomalous forms of the major histocompatibility antigens (H-2 in the mouse) found on normal cells of the individual in which the tumour arose. According to this view, the anomalous H-2 antigens would function as fire-alarms, signalling the transformation of a cell to the immune surveillance system.

A recent meeting* offered an overview of the evidence accumulated since then for the presence of anomalous H-2 antigens on tumour cells. The meeting confirmed published evidence that many tumours lose antigens: a heterozygous lymphoma cell line, LDHB, does so spontaneously at a very high rate in culture (B. Holtkamp, University of Cologne). On the other hand, tumours may gain H-2-like antigens. Some mouse tumour cells express H-2-like antigens which in normal spleen cells from the same mouse strain are detectable only in lysates and even then in lower amounts than in the tumour cells. This is the case for the DBA/2 lymphoma, SL2 (P. Robinson, Deutsche Krebsforschungszentrum, Heidelberg) and a retinal cell sarcoma (B. Bonavida (University of California, Los Angeles).

A spontaneous AKR ($H\text{-}2^k$) leukaemia, K36, apparently loses expression of antigens controlled by the $H\text{-}2K^k$ locus, as detected serologically or by T killer cells specific for the $H\text{-}2K^k$ locus. Furthermore, K36 appeared to express two different allelic products of the H-2D locus: the expected $H\text{-}2D^k$ antigen and new $H\text{-}2D^d$-like specificities. W. Schmidt (London Hospital Medical College) showed preliminary peptide maps of the $H\text{-}2D^d$-like antigen precipitated from the K36 tumour cells. These maps were very complex, presumably because of coprecipitated viral antigens; but they seemed to contain all the peaks found in a peptide map of $H\text{-}2D^d$ from normal cells.

The most persuasive evidence for anomalous specificities on tumour cells came from F. Garrido (Facultad de Medicina, Cordoba) and V. Schirrmacher (Deutsche Krebsforschungszentrum, Heidelberg) who have studied MCG4, a methylcholanthrene-induced BALB/c ($H\text{-}2^d$) tumour which has been converted to growth as ascites. The expected $H\text{-}2^d$ antigens were expressed only weakly on the tumour cells. Normal BALB/c mice

*A meeting on 'H-2 Antigens: Genetic Control and Expression on Normal, Tumour and Virally Infected Cells' was held at the London Hospital Medical College on 30 April-3 May. The meeting was sponsored by the European Molecular Biology Organisation and the Cancer Research Campaign of Great Britain.

© Macmillan Journals Ltd 1979

responded to the tumour cells with formation of cytotoxic T cells and of antibodies; the latter reacted with cells of almost all mouse strains (except H-2^d strains). Although the MCG4 cells did not express the private serological specificities of H-2^k, they did react with four different monoclonal BALB/c anti-H-$2K^k$ antibodies. Furthermore T killer cells which specifically attacked MCG4 cells also recognised H-$2K^k$ and H-$2D^k$. MCG4 may also carry some H-2^b-like specificities.

Susceptibility of the tumour cells to BALB/c killer cells raised against foreign H-2 antigens does not prove the presence of a particular gene product, because such killer cells are known to be very cross-reactive (more evidence on this point was presented by C. Neauport-Sautes, IRSC, Villejuif). More dramatic was the demonstration that Sendai virus-infected MCG4 tumour cells, but not virus-infected BALB/c lymphoblasts are susceptible to H-$2K^k$-restricted T killer cells from B10.A(4R) mice specific for Sendai virus. Because H-2 restricted killer cells are generally extremely specific, this was taken as evidence that MCG4 expressed the restriction specificity of H-$2K^k$. It must, however, be noted that two cases were presented at the meeting where precisely H-$2K^k$ restricted T killer cells could recognise other restriction elements: Elizabeth Simpson (Clinical Research Centre, Harrow), showed that male-specific killers also reacted with H-$2D^k$ male target cells, and W. Haas (Basel Institute for Immunology) has shown that even cloned killer cells specific for the hapten SP, killed hapten-coupled cells carrying H-$2D^k$, H-$2D^s$ or H-2^r antigens.

Are the new H-2-like specificities transplantation antigens? This seems to be the case for MCG4 which grows better in (BALB/c × H-2^k)F_1 mice than in BALB/c, the strain of origin. Immunisation of BALB/c mice with BALB.K (H-2^k) cells increases their resistance to C-1, another BALB/c tumour found by G. Parmiani and G. Invernizzi (Istituto Nazionale per lo Studio e la Cura dei Tumori, Milan) to express H-$2K^k$ serological specificities. That this tumour was rejected equally efficiently by several (BALB/c × H-2^k)F_1 hybrid mice and by BALB/c may mean that the tumour cells have other TSTA in addition to the H-$2K^k$-like ones. H-2-like TSTA is one possible explanation why M. Bortin (Mount Sinai Medical Center, Milwaukee) could induce resistance in AKR mice to syngeneic leukaemia by immunisation with pooled allogeneic cells, carrying many different foreign H-2 antigens. On the other hand, E. Lennox, (MRC Laboratory of Molecular biology, Cambridge) could biochemically separate the TSTA of a couple of methylcholanthrene-induced tumours from their H-2 antigens by their different affinities for lectins.

In spite of the many reports of new H-2-like antigens on tumour cells, other laboratories study tumours without finding such evidence, and the devil was not short of advocates at the meeting. C-1 is the only tumour so far which has been shown to have the same isoenzyme markers as the presumed strain of origin. But neither this test, nor an analysis of frozen samples of the very mouse from which the tumour was taken would exclude a mix-up with another cell line from an H-2 congenic strain during the many passages in mice or in culture.

Special caution is needed in the interpretation of serological data. Are the antigens detected on tumour cells with anti-H-2 sera also structurally H-2-like, and are the antigens detected by syngeneic antitumour sera on normal mouse cells from other strains H-2-like, not only in strain distribution, but also in tissue distribution and ontogeny? P. Ivanyi (Central Laboratory of the Netherlands Blood Transfusion Service, Amsterdam) presented a cautionary example of an anti-H-2^b serum raised in a virus-free B10.A(H-2^a) line against C57BL/10 cells from a line carrying a milk-transmitted virus. Although these antibodies were completely removed by absorption with virus-free C57BL/10 cells, and thus were H-2^b specific, they also reacted with syngeneic B10.A cells from a line carrying the same virus. This antigen, which was dependent on the milk-transmitted virus, did not appear on spleen cells until day 17 after birth.

In no case has it yet been demonstrated that the new H-2-like specificities are actually encoded by chromosome 17 (as are the known H-2 specificities), but assuming this is so, how do they arise? It has been proposed that "the serologically detected allelic differences [of H-2] are actually the products of different, closely linked genes, and the genetic polymorphism is for the control of whichever of the genes is expressed" (Bodmer *Transplant. Proc.* **5**, 1471; 1973). The day now seems close when this hypothesis will be tested directly by isolation of the genes of the H-2 complex and sequencing of the DNA. According to this model, new H-2-like specificities on tumour cells could arise by derepression of the corresponding genes. The current argument against derepression (and incidentally against a mix-up of cell lines) is that the anomalous antigens had only some, not all, of the specificities of known H-2 haplotypes: an H-2^d tumour might cross-react with H-2^k at the T cell level but still lack the private serological specificities of H-2^k.

Mutation seems a likely cause of new specificities. In normal mice mutations can occur in H-2K and H-2D fairly frequently (4×10^{-5} per locus per gamete). Such mutants have been detected by their ability to cause skin graft rejection. Studies *in vitro* on cytotoxic T cell reactions between mutant and wild type cells (K. Melief, Netherlands Cancer Institute, Amsterdam) showed that such mutations give rise to multiple new specificities, some of which cross-react with known foreign H-2 antigens (Nabholz *et al. Immunogenetics*, **1**, 457; 1975). J. Martin (National Cancer Institute, Bethesda) showed that a transplacentally-induced lung tumour from a C3HfeB/HeN mouse — this strain apparently carries an H-$2K^k$ mutation — expresses wild type H-$2K^k$ antigens, as if it were a revertant, and grows progressively in normal C3H/HeN mice.

Considering the strong reactions elicited by mutant cells, the report by S. Nathenson (Albert Einstein College of Medicine, New York) on the amino acid sequence analysis of eight H-$2K^b$ mutants was indeed surprising. Seven of these had only a single amino acid substitution, and one had two, five residues apart. Furthermore, the changes were all conservative, such as methionine to leucine. Nathenson presented a model in which the H-2K molecule can be likened to a bow knot, the N-terminal end sticking out from the cell surface, the C-terminal end traversing the cell membrane, and two domains held by cystine bridges forming the loops. All the mutations were clustered around the two cysteines of the first domains, suggesting that this is the site of prime importance for T-cell recognition (some of the mutations even lead to changed restriction specificity for virus-specific killer cells). It is not known whether the many amino acid differences between alleles at the N-terminal end play a part serologically.

The reason for the strong T cell reactivity to H-2 mutants may be that T cells during their development are selected for their ability to see minor alterations of self. Presumably somatic mutants that express altered H-2 antigens arise all the time and are normally eliminated by the immune system. It seems structurally almost unavoidable that altered self H-2 antigens would share specificity with one or more foreign H-2 antigens, and priming against such altered self determinants might account for the high frequency of alloreactive T cells in a normal mouse. □

Glueballs without gullibility

from Probir Roy

A glueball is a newly proposed form of neutral, unstable, quarkless hadronic matter and as such is currently engaging the attention of high energy particle physicists. Hadrons, the strongly interacting elementary particles, are assumed to be composed of pointlike (that is structureless) permanently confined constituents, the quarks. Apart from its spin of half, and fractional charges $\frac{2}{3}$ and $-\frac{1}{3}$

0028-0836/79/280106-03$01.00

© Macmillan Journals Ltd 1979

in units of the proton charge, each quark carries three kinds of a quantum number called colour. Colour is necessary to satisfy the antisymmetrical Fermi–Dirac statistics property of quarks in describing baryons as three-quark composites, the three quarks being in a colour-antisymmetrical state. Colour is also carried in eight different kinds by massless boson quanta (of spin one) called gluons. These are responsible for keeping the quarks 'glued' together in a hadron and are themselves also confined. One special property of colour forces mediated by gluons is the self-coupling of three gluons carrying different colours. As a result, the colour forces become weaker and weaker at shorter and shorter distances. This phenomenon is poetically described as 'asymptotic freedom' and seems to have been observed experimentally (see *News and Views* **277**, 349; 1979). These forces are believed to become stronger at greater distances. The literary acronym for this behaviour is 'infrared slavery' and this is what is supposed to be responsible for colour confinement. According to this view all coloured objects (such as quarks and gluons) should be confined and only colourless hadrons should be observable.

Given the self-coupling of gluons, one can expect to see as real, unstable particles of zero or integral spin, colourless composites made out of gluons alone. These are the hypothetical (at present) glueballs. A glueball may be visualised as a composite of two or three gluons, in analogy to the quark–antiquark picture of a meson or the three-quark picture of a baryon. Several glueballs are likely to exist at different masses. It has been argued (*Nucl. Phys.* **B 130**, 328; 1977) that, owing to the asymptotic freedom of the colour forces, the decay of the lowest mass glueball into the usual hadrons ought to be somewhat inhibited. Consequently, it is expected to be more stable than a typical meson of the same mass. It should have a lifetime of the order of 10^{-21} rather than of the order of 10^{-23} as is usual for mesons. Higher mass glueballs will of course be generally more unstable.

The existence of glueballs was first proposed by Fritzsch and Gell-Mann in 1972. However, they remained an idle curiosity until an intriguing suggestion by Freund and Nambu (*Phys. Rev. Lett.* **34**, 1645; 1975) linked them to an important feature of high energy hadron–hadron collisions. The total cross-section for such collisions depends very weakly on the energy – a behaviour which had for many years defied any real understanding in terms of the otherwise successful Regge picture of exchanges of Regge trajectories on which hadrons lie. Freund and Nambu could provide a credible explanation if the dominant exchanges are those of new Regge trajectories on which real glueballs lie. They required glueballs to exist with spins two, one and zero with masses around 1.5 GeV.

The very existence of glueballs – let alone their masses – is still a matter of considerable theoretical controversy. It was proved by Coleman (*Comm. Math. Phys.* **55**, 113; 1977) that, if the colour forces are described by the laws of classical physics, glueballs cannot exist. In a classical world a glueball would show up as a concentrated colourless gluon-made packet of finite energy which does not spread. Coleman has shown however that all classical packet-like solutions of this theory radiate away their energy very fast. Of course, the nonexistence of classical glueballs says nothing about the existence of quantum glueballs. However, it suggests that a glueball would be a purely quantum occurrence. The question of the existence of a glueball in a quantum field theory is a difficult one but has nonetheless received some attention. Arguments have been given (though not universally accepted) for the existence of such objects in a quantum theory of colour forces in lower dimensions, but none has yet been found for the $(3+1)$ dimensional space-time in which we live.

Instead of pursuing such a general approach, model-builders have considered the glueball question in specific dynamical models. The bag model, which has been developed particularly by the MIT group, is one such scheme. In this, each hadron is considered as a bag in which quarks and gluons are kept confined by chosen boundary conditions. The bag generates volume pressure and/or surface tension to produce confinement. Gluon wavefunctions have been treated by analogy to the transverse electric and magnetic modes of electromagnetic fields confined within a spherical cavity. This approach leads to the prediction of glueballs with spins zero and two and with masses slightly less than 1 GeV.

Another set of models has been pursued by lattice theorists, led by Wilson. They quantise space-time and consider the theory of colour forces on a four-dimensional Euclidean (that is, $x_1x_2x_3x_4 = it$) lattice with nearly vanishing lattice spacings. Quarks and antiquarks, instead of being continuous fields, are attached to lattice sites and gluons identified with the links between such sites. A quarkless glueball then is a closed box of links with no loose ends. Such objects have been shown to exist with spins zero, one and two and their masses calculated by Padé approximant methods to be around 1.5 GeV.

Glueballs have been looked for experimentally although they are generally very difficult to produce in hadronic collisions. The gluons by and large play a passive role in these reactions. However, they do play a pivotal part in the decay of heavy quark–antiquark bound states ('quarkonia') produced by electron-positron annihilation at high energies: for

Incest re-assessed

IN his advisory article on incest (*News and Views* **279**, 192; 1979), May reinforces his theoretical calculations on the deleterious effects of parent–offspring and brother–sister matings by reference to a Czechoslovakian study reported by E.O. Wilson. As presented, the study provides overwhelming evidence to support May's hypothesis; however a closer examination of the original data must raise a number of doubts as to the validity of the control group employed.

In her study (*Hum. Hered.* **21**, 108; 1971) Seemanova reported that the mean and the modal maternal ages of the non-incestuous control group at childbirth were 24.9 and 21 years while those of the father–daughter matings were 18.9 and 16 years and the brother–sister matings were 19.9 and 14 years. Since the Czech data referred to births from 1933 to 1970, the low modal ages of the mothers in the two incestuous groupings are particularly significant when viewed against the secular decline in the age of menarche during that period (Tanner *Growth at Adolescence* Blackwell, Oxford, 1962) and the high incidence of chromosomal anomalies and congenital malformations associated with pregnancies close to menarche (Carr *Adv. Hum. Genet.* **2**,201; 1971).

A second area of doubt concerns the imbalance between the biological fitness of the parents in the incestuous and the non-incestuous matings. Of the 141 incestuous mothers, 20 were mentally retarded (of whom two additionally were deaf-mutes, two had congenital syphilis and two were epileptics), a further two were deaf-mutes and three were schizophrenic. Among the 46 control mothers, a subgroup of the incestuous mothers, only two were mentally subnormal (one additionally being a deaf-mute) and two others were deaf-mutes. Similarly, of the 138 fathers in the incestuous matings 8 were mentally subnormal, 13 were chronic alcoholics, two had syphilis and four had committed suicide. In the non-incestuous grouping of 52 fathers, none were mentally subnormal, there were two chronic alcoholics and one case of polydactyly.

When considered in conjunction with the specific adverse social factors accompanying incestuous pregnancies, the conclusions on incest drawn on the basis of this particular study appear rather less convincing.

example, the J/ψ at 3.1 GeV and the upsilon at 9.4 GeV. In these bound states the heavy quark–antiquark pair can decay hadronically only by annihilating into three gluons in much the same way that positronium disintegrates into three photons. The gluons of course have to evolve into colourless hadrons later. The glueball may lurk among such hadrons. One interesting decay mode is when J/ψ goes into an energetic photon plus hadrons. Here the heavy quark–antiquark pair in the J/ψ annihilate into two gluons and a photon. The two gluons could resonate into a glueball in which case the photon will be highly monochromatic. Experiments done by the PLUTO group at the German storage ring DORIS have yielded good quality data for precisely this situation. They rule out the existence of any glueball up to a mass of 1.2 GeV, thereby demolishing the lighter than 1 GeV glueball of the MIT bag model.

Turning to the much heavier upsilon, the three gluons from its decay are expected to generate jet-like hadronic fragments. Normal electron-positron annihilation into hadrons by way of a quark–antiquark pair) above 6 GeV produces two symmetrical jets opposite each other. This jet structure survives the final 'colour-washing' that creates only colourless hadrons out of the quark and the antiquark. As each of the gluons from upsilon decay will on average carry an energy of nearly 3 GeV, gluon jets can be expected there. The three gluons should emerge symmetrically with 120° angles between one another, and there is some preliminary evidence for such events from PLUTO (*CERN Courier* **19**, 108; 1979). Another interesting possible configuration is one in which an energetic gluon dashes off to one side leaving two less energetic collinear ones opposite. This will lead to two jets opposite each other that are asymmetrical. According to a recent suggestion (Roy & Walsh *Phys. Lett.* **78B**, 62; 1978), the energetic gluon can now easily induce the creation of a gluon pair from the vacuum and capture one of its members to form a glueball. The latter should show up as a prominent, not very unstable resonance in one arm of the two jets and should disappear off the upsilon mass. Quantitative estimates, albeit hand-waving, have been made and look extremely favourable for the production and detection of glueballs in this manner, if they exist at all. □

Polymers for blood replacement

from Paul Calvert

SYNTHETIC blood volume expanders are sometimes used in cases of extensive bleeding or burns where much plasma has been lost, or in cases of shock, where contraction of the capillaries increases blood pressure so that water is lost to the tissues, the blood thickens and circulation ceases. Restoration of normal volume can be achieved by natural plasma, solutions of plasma proteins or by solutions of polymers such as dextran. Where blood or plasma are readily available the main reason for using a synthetic expander is to avoid the risk of hepatitis. On the other hand, in countries where blood supplies and storage and separation facilities are more limited, synthetic substitutes should be more important. So, recently published Chinese work on a volume expander derived from corn starch is of interest as an application of science to the needs of a developing country.

Blood has such diverse functions that it is difficult to imagine a completely satisfactory substitute. The role of a volume expander is simply to maintain the correct water balance between blood and the tissues and to allow continued transport of nutrients and gases. The water balance is determined by the osmotic pressure between blood and tissues, and the hydrostatic pressure difference. Lost volume can be restored by addition of an isotonic electrolyte solution such as Ringer's but this does not give the correct osmotic pressure balance as the electrolytes pass readily across membranes into the tissues. It is necessary also to restore the colloidal osmotic (oncotic) pressure normally provided by serum albumin which cannot cross the membrane and so balances the osmotic pressure of the macromolecular cell contents. In practice it does not seem to be agreed whether polymeric (or 'colloidal') solutions work better than salt solutions but they are certainly better in principle (see Pennell, in *Bibl. Haemat.* **29**, 883; 1968).

Solutions of a range of water-soluble polymers have been tried as volume expanders. The chief requirements are that the polymer is of sufficiently high molecular weight to prevent its loss through the kidneys, that it resists degradation and causes no harmful reactions. Dextran is chiefly used but hydroxyethyl starch has had successful clinical trials and polyvinyl pyrrolidone has been tested (Ricketts, *Brit. J. Anaesth.* **45**,958; 1973). Dextran has been used for about 30 years and its side effects are well studied (Gruber & Messmer, *Prog. Surg.* **15**, 49; 1977); Grönwall *et al.*, *Bibl. Haemat.* **29**, 874; 1968). High molecular weight dextrans cause clumping of red cells (rouleaux formation) though, interestingly from the colloid science viewpoint, molecules of low molecular weight lower even the natural degree of clumping. Reduced clumping leads to lower blood viscosity, promotes blood flow and exchange of nutrients with tissues and so is beneficial in shock cases. High molecular weight dextran has anticoagulant activity and it can be used for this purpose after surgery. Low molecular weight dextran is antigenic but there is no evidence for this with clinically-used dextran, although allergic reactions occasionally occur. Various dextrans in the molecular weight range of 40,000—110,000 are used depending on the balance of effect desired.

The Chinese work is from the Institute of Organic Chemistry in Shanghai, one of the three big polymer research groups in China. They describe the production of sodium carboxymethyl amylose by carboxymethylation of amylose from corn starch (*Acta Chimica Sinica* 36, 49 (1978). The molecular weight of the product was characterised by ultracentrifugation, solution viscometry, fractional precipitation and osmotic pressure. Using ^{14}C-labelled carboxymethylation followed by hydrolysis and paper chromatography the reaction was shown to occur primarily on the 2-oxygen. The degradation rate of the polymer in blood decreases with increasing carboxymethylation. A 5% solution of the polymer (molecular weight 60,000, 0.4 carboxyl methyl groups per saccharide) in 0.9% saline is now being tested in animals. It maintains blood volume for 6 h, is 90% lost in 24 h and is said to lack the immunological reactions of dextran. A possible snag, however, is that similar charged polymers are reported to enhance clumping (see Rickets *op.cit.*)

This work is interesting in the Chinese context for a number of reasons. It is a piece of careful, thorough polymer science. It describes the development of a new material from an available resource to replace the complex fermentation process needed for dextran. The work is original, whereas much of polymer science in China has been devoted to reproducing Western materials from patents. Also the work was done between 1961 and 1964 and has waited 15 years to be published. It shows that a relatively modest project can produce something adapted to local needs.

Most Western interest in this area seems to be in the more dramatic problem of an artificial blood substitute capable of carrying oxygen, particularly for organ storage. Geyer (*Drug Design* **VII** (ed. Ariens) Academic Press, 1976), has reviewed these with particular regard to emulsions of perfluorochemicals. With these he was able to replace completely the blood of rats so that they survived in 100% oxygen for 10 days until their red cells regenerated and they could be returned to air. Interestingly, these bloodless rats could also survive in 10% carbon monoxide. Cell-free haemoglobin solutions have also been used for blood replacement but they are degraded and must be continually transfused. There is obviously potential here for an oxygen-chelating polymer but a suitable molecule does not yet seem to be available □

review article

Hormonal regulation of peptide receptors and target cell responses

K. J. Catt, J. P. Harwood, G. Aguilera & M. L. Dufau

Endocrinology and Reproduction Research Branch, National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland 20205

Regulation of plasma membrane receptors for peptide hormones by the prevailing ligand concentration often causes altered target cell function. Receptor number is determined by hormone-induced changes in membrane conformation, irreversible ligand binding, and processing of ligand–receptor complexes during hormone action.

THE ability of target cells to respond to changes in ambient ligand concentration by regulating the number and/or affinity of their surface receptors is now so widely documented in hormone-regulated tissues that the absence of receptor regulation is now considered an unusual finding. Self-regulation of membrane receptors, originally observed with surface antigens, has been demonstrated in cells exposed to ligands including neurotransmitters, peptides, protein and glycoprotein hormones, and surface-modulating factors such as lectins and immunoglobulins[1]. Desensitisation of cellular responses by hormonal ligands has been observed in certain target cells, and in some cases has been correlated with loss of receptor sites—'down-regulation'. The mechanism of receptor regulation by homologous ligands probably depends on the ability of peptide hormone receptors to behave as mobile entities within the plasma membrane. The mobility of hormone receptors is evident during their interactions with membrane effector proteins such as adenylate cyclase, and in ligand-induced patching and capping of receptors[2]. Investigations of the fate of receptors during ligand-induced regulation have drawn attention to the ability of peptide hormones to enter their target cells, in contrast to the previous view that internalisation was a minor or negligible aspect of protein hormone action[3].

The effects of hormone stimulation on target cells include a complex series of events that not only evoke the characteristic cellular response, but also regulate the components of the activation pathway and modify the response to subsequent hormone stimulation. This article reviews recent work on the regulation of hormone receptors, with emphasis on the mechanisms and consequences of receptor regulation and desensitisation in target cells for insulin, catecholamines, angiotensin II and gonadotropins.

General aspects of receptor regulation

The concept of intrinsic membrane proteins diffusing laterally within the lipid bilayer[4] led to the notion that the mobility of receptors within the membrane was responsible for features of peptide hormone action such as the activation of common membrane responses by multiple independent ligands[5], desensitisation, negative cooperativity, and the dependence of receptor affinity on the presence of membrane effector systems[6]. One prediction of the hypothesis of mobile receptors is that the receptors should be physically independent of adenylate cyclase in systems where the response is effected via adenylate cyclase. That prediction is borne out by the resolution of the two activities in detergent-solubilised membranes from cells bearing receptors for glucagon[7], luteinising hormone (LH)[8], or catecholamines[9], by the coupling of receptors from one cell type with the heterologous adenylate cyclase of another cell type when the two are fused[10,11], and by the functional transfer of solubilised ovarian LH receptors to isolated adrenal cells[12]. This evidence suggests that there is a universal mechanism of coupling between receptors and adenylate cyclase but characterisation of solubilised receptors[13–17] has not yet revealed the molecular basis of the supposed coupling.

Edelman[2] has suggested that cell growth, movement and recognition are coordinated by a supramolecular complex of cell-surface receptors and submembranous fibrillar structures, by which changes (surface modulation) in receptor conformation, mobility and distribution lead to changes in the associated cytoplasmic components. These structural interactions are probably responsible for the aggregation (clustering, patching and capping) of receptors that is induced by cross-linking agents such as divalent antibodies and multivalent lectins.

The clustering of receptors into surface aggregates is an important prelude to internalisation of hormone–receptor complexes, as discussed below but may also be important in the acute phase of hormone action. Thus, bivalent antibodies to the insulin receptor can both bind to receptors and exert insulin-like actions in isolated adipocytes[18]. In contrast, monovalent Fab' antibody fragments, although binding to the receptor, do not evoke a biological response. Addition of anti-$F(ab')_2$ antiserum cross-linked the Fab' receptor complexes and restored the insulin-like action of the antibody; also, anti-insulin antibodies enhanced the biological activity of low concentrations of insulin. These effects were independent of microfilaments and microtubules, and indicated that receptor cross-linking or aggregation is important in the insulin-like effects of anti-receptor antibodies and perhaps in the actions of insulin itself. This proposal is consistent with findings that insulin receptors are mobile[19] and can form clusters[20] in the cell membrane, and with the ability of lectins[21] to exert insulin-like effects.

Many peptide hormone receptors are regulated by the homologous hormone, and sometimes by other hormones. Increased hormone concentrations usually cause a decrease in the respective receptors, as demonstrated originally by Roth and co-workers for the insulin receptor of liver[22,23] and cultured lymphocytes[24]. Such down-regulation of insulin receptors occurs in human obesity[25] and in genetic or induced obesity in rodents[26], and probably reflects the action of excess circulating

insulin to decrease insulin receptors. Such receptor loss seems to be a general consequence of the raised blood insulin levels associated with insulin-resistant states. The converse effect, of increased insulin receptors in states of reduced insulin secretion, has been observed in the liver of diabetic hamsters and rats[27,28]. Other receptors down-regulated by the homologous hormones include those for growth hormone, thyrotropin-releasing hormone, catecholamines, gonadotropins and glucagon[29-33]. Certain peptide receptors, such as those for prolactin[34] and angiotensin II[35], may increase in number after exposure to elevated hormone concentrations, but the more common response is loss of receptors from the cell surface. Some receptors, notably those for insulin, may exhibit negative cooperativity on exposure to increased ligand concentrations. This represents an additional form of receptor regulation, in which partial occupancy leads to decreased affinity of the residual sites, with acute reduction of target cell sensitivity in the presence of increased insulin concentrations[36]. Hormone-induced receptor loss has sometimes been found to be dependent on protein synthesis[30,36] and sometimes not[29,31], but the return of peptide receptors seems to require new protein formation[29]. The details of the processes leading to receptor depletion and replenishment are still not clear.

An important factor in receptor regulation is the incompletely reversible nature of the complex formed after the initial phase of hormone binding to the receptor. Analysis of hormone–receptor interactions has traditionally involved methods based on the assumption that the complex is reversible, but kinetic studies have frequently shown the hormone–receptor complex to have an initial rapid phase of dissociation, followed by a prolonged phase of slow and incomplete reversal[37]. This suggests that the initial interaction with hormone leads to a conformational change in the receptor that results in tighter binding of the ligand. One view is that the higher-affinity binding state is brought about by interaction of occupied receptors with adenylate cyclase[38], but similar changes are evident in receptors considered not to operate through adenylate cyclase, such as insulin[39] and angiotensin II[40]. In any case, prolonged occupancy by undissociated ligand is always a potential cause of functional receptor loss, and should be evaluated during studies of receptor regulation. For this purpose, uptake and release of labelled ligand and direct assay of occupied and free sites should be performed, since multiple washing steps and unchanged basal adenylate activity do not exclude residual occupancy by the agonist ligand. As well as causing apparent receptor loss by masking free binding sites, continued occupancy by ligand favours the probability that hormone–receptor complexes will be degraded or otherwise processed and destroyed. This could involve occlusion within the cell membrane or shedding from the cell surface, but accumulating evidence favours a process of endocytosis and subsequent lysosomal breakdown of the internalised hormone–receptor complexes.

Effects of receptor regulation on cell responses

Implicit in the interpretation of receptor regulation has been the expectation that end-organ responsiveness will be altered by changes in receptor concentration. If no other changes occurred, a reduction in membrane receptors would be expected to decrease target-cell sensitivity in tissues containing abundant 'spare' receptors, and to decrease the magnitude of the target-cell response when receptor concentration became the limiting factor in the ability to elicit a hormonal response. The general function of receptor regulation as a mechanism to decrease target-cell sensitivity in the face of high hormone concentrations could have certain biological advantages. An obvious example is blood glucose homeostasis, in which decreased insulin receptors and reduced sensitivity of peripheral tissues to insulin would blunt the effect of hyperinsulinaemia on circulating glucose concentration. Receptor regulation could also minimise or buffer the cardiovascular responses to excessive levels of angiotensin II and catecholamines. This could account for the marked resistance to angiotensin II that occurs in many clinical states of increased renin secretion. However, the biological function of receptor regulation is less evident for other stimulators, such as growth hormone and gonadotropins, which exert more long-term biological effects on their target cells.

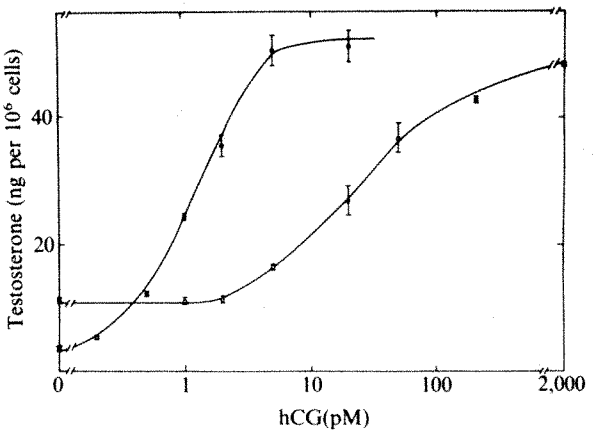

Fig. 1 Decreased sensitivity of testosterone responses of desensitised Leydig cells to gonadotropin stimulation *in vitro*. Cells were prepared from testes of adult male cats treated 48 h earlier with 10 μg hCG by subcutaneous injection (O), or from untreated controls (●). The loss of LH receptors causes a marked increase in the ED_{50} for hCG-stimulated testosterone production.

The effects of receptor regulation on cellular responses to hormones have been studied in several tissues, particularly target cells in which hormone action is mediated by the adenylate cyclase–protein kinase system. Intact cells are particularly useful for such studies, because hormone binding and cyclic AMP production can be correlated with the ultimate cell response[41]. Also, the cyclic AMP produced during hormonal stimulation of isolated cells frequently accumulates in the medium, providing a sensitive index of receptor activation. An important distinction to be made in the study of such hormone-treated tissues is the difference between acute desensitisation (usually of adenylate cyclase) without receptor loss, and the development of true receptor loss, which is a delayed and more slowly reversible consequence of hormone–receptor interaction.

Analysis of the level at which regulation of surface receptors causes altered metabolic responses depends on the ability to measure changes in the hormone-activated pathway that is triggered by receptor binding. For several peptide hormones, such as insulin, growth hormone and prolactin, the immediate mechanism of action on target cells is still unknown. Thus, although insulin indirectly modulates several membrane enzymes, including adenylate cyclase, phosphodiesterase and ATP-ase, the relationship of these effects to its actions on membrane transport systems and anabolic responses remains unclear[42]. Where early events in hormone action have not been identified, the effect of receptor regulation on cell responses can be examined by measuring changes in transport systems and biosynthetic processes. This approach has been used to analyse the effects of insulin receptor regulation in adipocytes or hepatocytes, on glucose or amino acid transport and lipid synthesis[43,44].

The consequences of receptor regulation on target cell function have been extensively studied in steroidogenic cells of the testis and ovary, which respond to trophic hormones with specific steroid secretion via an adenylate cyclase-dependent mechanism. The Leydig cell of the testis and the luteal cell of the ovary possess high-affinity LH receptors that are readily measured with ^{125}I-labelled human chorionic gonadotropin (hCG) and are coupled to steroidogenesis through the adenylate cyclase–cyclic AMP–protein kinase pathway[41,45]. In these cells it is possible to analyse several levels of response, from receptor

occupancy through cyclic AMP production and kinase activation, to stimulation of pregnenolone production and subsequent biosynthetic steps leading to progesterone and testosterone production. Analysis of these processes in enzyme-dispersed cells during hormone stimulation permits evaluation of the changes induced by gonadotropin levels similar to those regulating cell responses *in vivo*. When cells are prepared after desensitising doses of gonadotropin, marked changes in LH receptor content and metabolic responses to hormone stimulation are evident *in vitro*. As described below, such desensitised cells provide evidence for several consequences of receptor regulation induced by hormone treatment in the intact target tissue.

Regulation of β-adrenergic receptors and adenylate cyclase

The actions of catecholamines on receptors and adenylate cyclase have been analysed in avian and amphibian erythrocytes, and in cultured cells bearing β-adrenergic receptors. The ultimate cellular actions of catecholamines in most of these test systems are not yet known, although an association with ion transport has been described in the avian erythrocyte[46].

Measurement of β-adrenergic receptors has been performed by binding assays with labelled antagonists, either ^{125}I-hydroxybenzylpindolol[47] or ^{3}H-dihydroalprenolol (DHA)[48]. In frog erythrocytes, binding studies with DHA have shown available β-adrenergic receptors and adenylate cyclase responses to be reduced by previous exposure to catecholamines[31,48]. In contrast, the β-receptors in turkey erythrocytes do not exhibit altered binding properties on exposure to adrenergic stimuli (G. D. Aurbach, personal communication). The desensitising action of catecholamines in frog cells can be blocked or reversed by the β-adrenergic antagonist propranolol, which does not itself cause desensitisation. These findings indicate that desensitisation or tolerance to catecholamines is caused by a reduction in the number of functional β-adrenergic receptors. It is likely that chronic occupancy by agonist rather than an active process of receptor loss is responsible for the decreased receptor number, as the ligand-induced changes in receptor number and adenylate cyclase were not altered by treatment with cycloheximide to inhibit protein synthesis[49]. Desensitisation was also observed in erythrocyte membranes exposed to β-adrenergic agonists *in vitro*, but was not produced by antagonists such as propranolol, and could be reversed by guanyl nucleotides[50]. These findings suggest that receptor binding of agonist is followed by coupling of the complex to adenylate cyclase, a process accompanied by conformational changes that initially activate the enzyme and subsequently produce the refractory state known as desensitisation. A requirement for such coupling would account for the inability of antagonists to induce desensitisation, and of guanyl nucleotides to reverse desensitisation by enhancing dissociation of the receptor-bound agonist.

Subsequent studies on the interaction of erythrocyte receptors with a labelled β-adrenergic agonist, ^{3}H-hydroxybenzylisoprenaline (HBI), revealed that dissociation of bound agonist is much slower than that of antagonists such as ^{3}H-DHA, and is significantly accelerated by guanyl nucleotides[51]. The persistence of agonist binding could be responsible for desensitisation of β-adrenergic receptors in cell membranes exposed to agonists *in vitro*, and for the apparent loss of receptors measured with labelled antagonists. Formation of the high-affinity complex between β-receptor agonists and adenylate cyclase-coupled receptors is dependent on magnesium, which increases receptor binding affinity for agonists but not for antagonists[52]. This finding, and the absence of a magnesium effect in solubilised receptors, implies that coupling of receptors to adenylate cyclase is involved in the formation of the high-affinity agonist binding state. Confirmation of this comes from the finding that mutant lymphoma cells deficient in adenylate cyclase did not lose receptors on exposure to isoprenaline[53]. In contrast, wild-type cells and mutants deficient in protein kinase, showed loss of β-receptors and adenylate cyclase responses after incubation with isoprenaline, although the kinase mutants lacked the induction of phosphodiesterase seen in normal cells. Thus, activation of adenylate cyclase, but not changes in protein kinase and phosphodiesterase, appears to mediate the decrease in β-receptors and cyclic AMP responses of cells exposed to catecholamines. However, solubilised turkey erythrocyte membranes showed increased affinity for agonists, but not for antagonists[54], so that the formation of a high-affinity agonist binding complex may not depend only on coupling to adenylate cyclase.

Recently, comparison of agonist and antagonist binding assays has shown discrepancies in receptor numbers measured after β-adrenergic desensitisation of frog erythrocytes with isoprenaline in *vitro*[55]. Whereas the loss of available sites measured with the labelled agonist ^{3}H-HBI was correlated with loss of adenylate cyclase responses, binding of the labelled antagonist ^{3}H-DHA was significantly less impaired. In a related study, desensitisation of frog cells by exposure to the radiolabelled agonist led to a loss of antagonist binding sites that exceeded the measured occupancy by residual agonist[56]. These findings raise the possibility that prolonged high-affinity binding of agonist does not entirely account for the loss of β-adrenergic receptors measured by binding studies with labelled alprenolol. Whether this indicates that antagonist sites are regulated independently of agonist sites has yet to be determined. However, it is clear that occupancy of β-adrenergic receptors by agonist ligands is of higher affinity than anticipated from antagonist binding studies, and that *in vitro* desensitisation of adenylate cyclase is probably associated with sustained receptor occupancy.

A physiological role for regulation of β-adrenergic receptors was suggested by the observation that sympathetic control of *N*-acetyltransferase and melatonin synthesis in the rat pineal gland was modulated by marked changes in β-adrenergic receptor number and adenylate cyclase responsiveness during the diurnal light–dark cycle[57]. Pineal glands of light-exposed rats contain more β-receptors and adenylate cyclase than glands from animals kept in the dark, and treatment with isoprenaline causes marked loss of both receptors and enzyme responsiveness to β-agonists. These changes seem to be involved in the varying sensitivity of the pineal gland during light–dark cycles, by modulating the capacity to form cyclic AMP in response to β-adrenergic stimulation. The desensitisation of pineal receptors by catecholamine, as in the frog erythrocyte[48], was not affected by cycloheximide, again suggesting that inactivation and reactivation, rather than receptor turnover, were responsible for the changing receptor concentrations. Modulation of β-adrenergic receptor binding of agonist ligands has also been noted in the myocardium, where guanyl nucleotides reduce binding affinity for agonist but not antagonist ligands[58]. In this tissue, muscarinic cholinergic agents antagonised the GTP-induced reduction in β-receptor affinity for isoprenaline, and attenuated the combined effect of GTP and isoprenaline on myocardial adenylate cyclase. These findings suggest that cholinergic agonists can act through the muscarinic receptors to regulate both β-receptors and adenylate cyclase by modulating the effects of GTP. This action is consistent with the known ability of the cholinergic system to attenuate the cyclic AMP-mediated effects of sympathetic stimulation.

Regulation of gonadotropin receptors and gonadal steroidogenesis

In the Leydig cell of the testis and the luteal cell of the ovary. LH binds to plasma membrane receptors with high specificity and affinity ($K_d = 0.1$ nM). Hormone binding is followed by activation of adenylate cyclase and increased formation of cyclic AMP, which stimulates production of testosterone in Leydig cells and progesterone in luteal cells[59]. Administration of ovine LH or hCG to rats is followed by prolonged loss of LH receptors in gonadal homogenates[60] and membrane preparations[61], as well as in purified Leydig[62] and luteal cells[63]. The decrease of receptor number is both time- and dose-dependent[60–64], and is

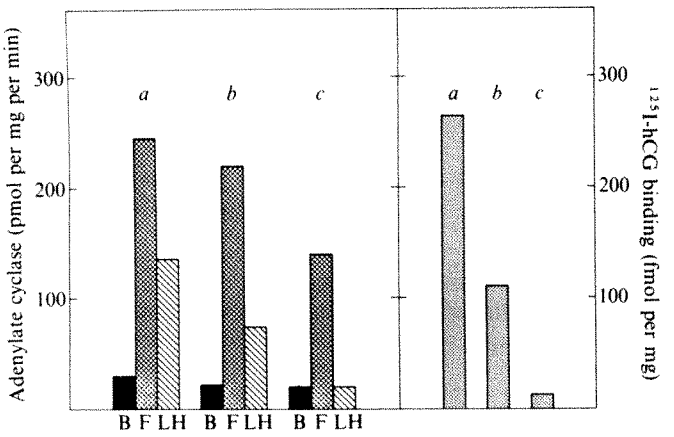

Fig. 2 Concomitant loss of LH receptors (right) and of adenylate cyclase responses to LH (left) in ovarian homogenates from rats treated 24 h earlier with 0.1 μg (*b*) and 20 μg (*c*) of hCG. The control levels of binding and adenylate cyclase (*a*) are shown at the left of each panel. For adenylate cyclase activity, basal (B), fluoride-stimulated (F) and gonadotropin-stimulated (LH) values are shown.

accompanied by prominent changes in the cyclic AMP and steroid responses of the desensitised cells[63,65]. The expected effect on Leydig cell sensitivity to gonadotropins after receptor loss (an increase in the ED_{50} for steroid production) is observed after subcutaneous treatment with hCG, as shown in Fig. 1. However, more marked receptor loss, particularly after intravenous treatment with hCG, is accompanied by a decreased maximum steroid response to subsequent hormone stimulation.

Of particular significance in studies of receptor regulation is the demonstration that the initial loss of LH binding capacity is due to occupancy of LH receptor sites by the desensitising dose of the hormone used to treat the animal[61,65]. This has been shown by administration of ^{125}I-hCG, and directly by elution and radioimmunoassay of receptor-bound hCG after treatment with the unlabelled hormone. The initial occupancy stage, which lasts for up to 24 h, is followed by prolonged loss of LH receptors which is maximum after 1 to 2 d and lasts for up to 8 d in both testis[65] and ovary[66]. After treatment with a low dose of hCG (200 ng), maximum receptor loss of about 60% is evident at 4 d. At this time, the decrease in binding cannot be due to occupancy, and represents depletion of LH receptors from the plasma membrane. The extent of true receptor loss is much greater than the initial occupancy by administered hormone[61,65], as also noted after growth hormone binding to cultured lymphocytes[29]. These findings suggest that the initial occupancy induces an active or cooperative process in the cell membrane that augments the degree of receptor loss. In both testis and ovary, the period of net receptor loss is followed by return of the receptor number to normal over the next 6 to 10 d. The reappearance of gonadotropin receptors probably depends on synthesis of new receptor protein rather than recycling or reactivation of the lost receptor sites.

Receptor regulation in the testis and ovary has also been demonstrated following elevation of endogenous LH levels by administration of gonadotropin-releasing hormone (GnRH or LHRH) and its analogues. These studies also revealed marked and reversible loss of prolactin receptors, and regression of testis function[67–69]. Administration of GnRH to pregnant rats caused a fall in progesterone secretion and termination of pregnancy[70], probably due to functional luteolysis following loss of ovarian receptors for prolactin and LH, and desensitisation of the corpus luteum of pregnancy[71]. In addition, a direct effect of GnRH on the ovary may contribute to these regressive changes.

The disappearance of functional LH receptors, whether due to initial occupancy or subsequent receptor loss, is accompanied by decreased ability of LH to stimulate adenylate cyclase activity and cyclic AMP formation in the ovary[61] and testis[65]. At the time of true receptor loss, the receptor number correlates with the degree of adenylate cyclase stimulation by LH in ovarian particles (Fig. 2). Subsequently, the recovery of receptors is accompanied by restoration of LH-stimulation of adenylate cyclase. Modulation of receptor number and adenylate cyclase stimulation has been shown with low doses of hCG, equivalent to the LH levels that occur during the normal reproductive cycle in the rat. Changes in adenylate cyclase responsiveness to LH after both induced and spontaneous ovulation[72,73] suggest that receptor regulation and its consequences play a part in the regulation of ovarian function. Apart from their relevance to receptor regulation, these studies provide evidence that the binding sites measured with ^{125}I-hCG represent the functional LH receptors that are coupled to adenylate cyclase and the steroid activation mechanism.

The loss of adenylate cyclase responsiveness to gonadotropins during receptor occupancy shows that the gonadal enzyme, like that of the frog erythrocyte, becomes refractory after the initial hormone–receptor interaction. At this time, free LH receptors are still present but cannot undergo functional coupling to the catalytic unit of the enzyme. Transient loss of the fluoride effect on adenylate cyclase also occurs during desensitisation by hCG, with recovery in 24 to 36 h[74], corresponding closely with the occupancy phase of the LH receptors. Adrenaline can also stimulate adenylate cyclase in the ovarian luteal cell, and during hCG-induced desensitisation, when no loss of β-adrenergic receptors could be detected, there was decreased enzyme response to adrenaline[75]. These findings suggest that hormone interaction with the LH receptor is followed by a transient refractory state in which the system cannot be stimulated by occupancy of free LH receptors or β-adrenergic receptors, or by fluoride. This refractory state is reversed within 24 h, as shown by the return of the fluoride and adrenaline responses. In contrast, the loss of LH receptors results in a prolonged loss of receptor-mediated LH activation of adenylate cyclase for several days.

Changes in Leydig and luteal cell LH receptors and adenylate cyclase activation have marked effects on the responses of the intact cell to gonadotropins[62,63,76]. The production of cyclic AMP in desensitised cells is generally well correlated with changes in receptor number in both cell types, and steroid production is also reduced in proportion to receptor loss. In the ovary, treatment with 2 μg of hCG, enough to produce > 90% reduction in the luteal LH receptors, caused almost complete loss of cyclic AMP and progesterone responses in isolated cells stimulated with gonadotropin *in vitro*. A lower dose of hCG (100 ng) caused a 50% fall in the receptor number and produced a similar decrease in both cell responses. In the Leydig cells of the testis, there was again a close correlation between decreased receptor number and loss of the steroid response to hormone stimulation. However, loss of steroid production was not fully accounted for by loss of LH receptors and the consequent failure of cyclic AMP generation, because addition of dibutyryl cyclic AMP or cholera toxin to over-ride the block in cyclic AMP synthesis failed to stimulate steroid production[62]. In the ovary, the loss of steroid response to hCG in partially desensitised cells was also seen with cholera toxin and dibutyryl cyclic AMP, and in fully desensitised cells these two stimuli had no effect on progesterone production[63].

The nature of the additional block beyond the level of cyclic AMP formation was characterised in the Leydig cells from hCG-treated rats. Depending on the desensitising dose of hCG, decreased conversion of steroid precursors to androgens was evident at specific points in the biosynthetic pathway[77]. Although high doses of hCG caused a decrease in the formation of pregnenolone from cholesterol, lower doses of hCG did not impair the side-chain cleavage step while still causing a marked fall in androgen production. Detailed analysis of the testosterone biosynthetic pathway indicated that the 17, 20 desmolase step becomes rate-limiting in the desensitised state, with accumulation of 17-hydroxylated precursors. Also, reductions in 3β-hydroxysteroid dehydrogenase and 17-hydroxylase activi-

ties were suggested by the increased levels of pregnenolone and progesterone formed in desensitised cells. The mechanism by which gonadotropin treatment causes these reductions in enzyme activity has not been elucidated, but may depend on local inhibitory feedback by oestrogen produced during the initial stimulation by the desensitising dose of hCG. It is also likely that maintenance of the steroid biosynthetic pathway requires the 'trophic' influence of LH, and that receptor loss impairs this long-term action of gonadotropins as well as their acute effect on steroid biosynthesis and secretion.

Regulation of angiotensin II receptors and adrenal function

The renin–angiotensin system plays a major part in the control of aldosterone secretion during changes in electrolyte intake and sodium balance. This action is exerted through the binding of angiotensin II to specific receptors in the adrenal zona glomerulosa cells, with stimulation of aldosterone production via a non-cyclic AMP-dependent mechanism. In addition to this acute action on steroid secretion, the renin–angiotensin system exerts an important trophic action on the glomerulosa zone, as seen in prolonged sodium deficiency. The adrenal angiotensin II receptors are predominantly in the glomerulosa layer, and exhibit high-affinity binding of agonist and antagonist derivatives of angiotensin II, with association constants in proportion to their biological activities.

Angiotensin II receptors are regulated by the prevailing concentration of the peptide ligand[35], and also by changes in electrolyte intake[78]. The latter action is at least partly exerted through changes in blood angiotensin II concentration. Decreased sodium intake and increased potassium intake, which both markedly elevate aldosterone secretion, also cause increased angiotensin II receptor content in the glomerulosa cell[78]. Conversely, high sodium or low potassium intake, which both reduce aldosterone secretion, cause a decrease in adrenal receptors for angiotensin II. The sodium-induced changes are largely attributable to the altered renin secretion and angiotensin II concentrations that accompany variations in sodium intake. Thus, blood angiotensin II levels are increased in sodium deficiency and decreased in sodium loading, and both adrenal angiotensin II receptors and aldosterone secretion are commensurately altered by changing sodium intake. Changing potassium intake has the opposite action to sodium on angiotensin II levels, but the same effect on glomerulosa cell receptors and aldosterone production, by an independent direct effect of potassium on the zona glomerulosa.

During sodium deficiency, the adrenal becomes more sensitive to angiotensin II, whereas vascular smooth muscle becomes less sensitive and pressor responses to the octapeptide are blunted. These changes partly depend on altered receptor properties, as even short periods (36 h) of sodium deficiency caused increased binding of angiotensin II by the rat adrenal *in vivo* and *in vitro*, whereas sodium loading had the opposite effect[79]. Enhancement of binding by sodium restriction was due to a rapid increase in receptor affinity, followed within a few days by increased receptor content. Conversely, sodium loading resulted in a fall in the number of angiotensin II binding sites per adrenal glomerulosa cell. In each case, the aldosterone responses of isolated glomerulosa cells were commensurate with the changes in angiotensin receptors. Thus, cells exhibited increased sensitivity to angiotensin II when receptor affinity was raised, increased maximum aldosterone secretion when receptor content became elevated, and decreased responses when receptor content was diminished. These changes in receptors and steroidogenic activity of the glomerulosa cells contribute to the regulation of sensitivity and maximum responsiveness of the adrenal to angiotensin II during altered sodium balance. The presence of a converse effect in smooth muscle receptors during low sodium intake was consistent with the reduced sensitivity of vascular smooth muscle to angiotensin II during sodium deficiency. The contrasting effects of low sodium intake on adrenal and uterine smooth muscle receptors are shown in Fig. 3, the reciprocal changes in receptors being parallel to the altered sensitivity of each tissue to angiotensin II.

The trophic actions of angiotensin II in the glomerulosa cell include effects on angiotensin II receptors and enzymes in the steroid biosynthetic pathway, as well as on glomerulosa cell differentiation. Infusion of angiotensin II enhances adrenal sensitivity to the peptide in man and rat, and increases the angiotensin II receptor content of the rat adrenal, with an accompanying rise in aldosterone secretory capacity[35]. Although injection of large doses of angiotensin II can decrease the adrenal and uterine receptors in nephrectomised rats[80,81], treatment of intact rats with smaller amounts of angiotensin II has the converse effect, increasing angiotensin II receptors and aldosterone responses in the adrenal glomerulosa cell[35].

The ability of angiotensin II to cause positive regulation of its own receptor sites in the adrenal suggests that most or all of the effects of sodium deficiency on aldosterone secretion could be mediated by changes in angiotensin II secretion and adrenal sensitivity to angiotensin. This controversial concept has recently been supported by the results of direct assay of adrenal receptors and glomerulosa cell responses[79]. Further evidence has been provided by the use of an inhibitor of converting enzyme to prevent angiotensin II formation during sodium restriction, which would normally cause increased adrenal receptors and aldosterone production[82]. Blockade of angiotensin II generation during sodium restriction completely abolished the increased receptor binding and aldosterone responses that occur in sodium deficiency, indicating the importance of angiotensin II in mediating the adrenal response to altered sodium balance. This finding emphasises the central role of the renin–angiotensin system in the regulation of aldosterone secretion during short-term physiological changes in sodium intake.

Fate of the hormone–receptor complex

Most studies of peptide hormone action have concentrated on the acute responses that follow the binding of hormone to its cell-surface receptor. Much less is known about the equally important long-term actions on cell growth and differentiation, or about the termination of hormonal stimuli. These events may be related to the fate of the hormone–receptor complex. As noted above, there is evidence that the initial interaction is followed by formation of a higher-affinity binding state that causes the complex to remain associated for prolonged periods. That, together with increasing evidence for the presence of hormones and binding sites within target cells, has led to the

Table 1 Formation and degradation of the hormone–receptor (H–R) complex

Formation and actions of the H–R complex

A H–R becomes coupled to ACy or other effectors to form H–R–ACy
B H–R–ACy initiates acute response to hormone
C H–R–ACy complex becomes refractory (desensitisation)
D H–R becomes uncoupled from ACy

Fate of H–R complex

A H released, R re-utilised with turnover independent of occupancy (traditional)

or

B H–R released from cell surface (shedding)

or

C H–R internalised
1. Loss of occupied surface receptors (down-regulation)
2. Concomitant endocytosis of adjacent unoccupied receptors
3. Lysosomal degradation of H, possibly of H–R
4. Mediates intracellular trophic action

D H metabolised or inactivated, R remains in inactive (non-binding) form

The most clearly demonstrated mechanism of receptor regulation is by internalisation of the H–R complex. The other pathways could operate in specific tissues and their relative contributions probably vary with the functional state of the cell. ACy, adenylate cyclase.

view that internalisation is a frequent consequence of hormone–receptor interaction. Interest in this process was stimulated by demonstration of the uptake and turnover of cholinergic receptors[83] and low-density lipoprotein–receptor complexes[84]. Subsequently, increasing emphasis has been placed on the importance of internalisation in the processing of hormone–receptor complexes in endocrine target tissues. The mechanism of the internalisation process for peptide hormones probably has many features in common with the processes of surface modulation in lymphocytes[2] and the coated pit system responsible for uptake of macromolecules such as LDL[85]. The basis of the increase in target cell receptors induced by peptides such as angiotensin II and prolactin requires further study but is likely to be related initially to changes in membrane conformation and later to increased receptor synthesis.

Several studies have implicated cytoplasmic contractile elements in receptor mobility and regulation. In lymphoid cells, ligand–receptor interaction is followed by patch formation, aggregation into a few larger patches or a single cap, and finally by internalisation or shedding of the cross-linked receptors. Examination of surface receptor capping by fluorescence staining of the receptor-bound ligand and intracellular actin or myosin showed that patching of surface antigens in splenic T lymphocytes (and lectin receptors in HeLa cells) was accompanied by collection of actin or myosin beneath the aggregated receptors[86]. In the presence of sodium azide, the ligands induced a patchy redistribution of receptors and a concomitant rearrangement of membrane-associated actin on the cytoplasmic surface of the cell membrane. In the absence of azide, the patched receptors became capped, with accumulation of the underlying actin and myosin beneath the cap. These observations, and previous findings on Ig receptor capping in B lymphocytes[87], led to the proposal that a general mechanism of capping depends on the collection together of patches by actin and myosin, analogous to the sliding filament mechanism of muscle contraction[86]. This mechanism also provides a plausible link between capping and subsequent endocytosis, by the concerted action of actin and myosin to initiate invagination of the capped region of the cell membrane. Cellular contractile elements have been also implicated during capping of lectin receptors in cultured ovarian granulosa cells[88], in which microfilaments were active in the redistribution of surface receptors during capping, and microtubules had an orientating effect on the direction of flow of receptor complexes.

Although receptor patching and capping commonly occur in cells exposed to multivalent ligands such as immunoglobulins and lectins, the progression from patching to capping may not apply when receptors are occupied by univalent ligands such as hormones and transmitters. However, the processes leading to aggregation and internalisation of multivalent ligands may be relevant to the turnover and fate of peptide hormone receptors, particularly during receptor regulation in response to increased concentration of hormonal ligands. In recent studies, described below, redistribution of receptors for hormones and other univalent ligands has been found to precede internalisation of receptor aggregates and subsequent degradation of the complexes.

The association of hormonal internalisation with ligand-induced receptor loss was clearly documented for epidermal growth factor (EGF) in human fibroblasts[89]. The cell-bound mitogen was rapidly degraded in a manner consistent with internalisation and lysosomal breakdown, and surface receptors for EGF simultaneously disappeared from the cells. Loss of EGF receptors after peptide binding was also demonstrated by affinity labelling, which showed that rapid proteolytic processing of receptor–hormone complexes accompanied the decrease in membrane receptor sites[90]. Also, both receptor processing and DNA synthesis were stimulated half-maximally when 10% of the receptors were occupied by the mitogen. However, in cultured ovarian cells the luteinisation of granulosa cells was associated with increased EGF receptors and retention of the ability to internalise bound EGF, but with loss of responsiveness to the mitogenic action of EGF[91]. At least in these cells, there was no correlation between mitogenic activity and the capacity for EGF binding and internalisation.

Direct visualisation of the internalisation of fluorescent analogues of EGF and insulin has been achieved by image intensification during fluoresence microscopy[92]. The hormone–receptor complexes were initially distributed uniformly on the cell membrane, then rapidly became aggregated into patches that were internalised to form endocytic vesicles within the cytoplasm. These events could explain both the negative cooperativity of insulin receptors and the down-regulation of receptors and hormone degradation by target cells. Binding and internalisation of EGF has also been observed by conventional fluorescence microscopy in epithelioid carcinoma cells with 25 to 30 times more EGF receptors than in fibroblasts[93]. The bound EGF was again rapidly internalised as fluorescent endocytic vesicles, which later formed a prominent perinuclear ring. Although patch formation did not occur in the epithelioid cells, the occurrence of micro-clusters of receptors was demonstrated by electron microscopy after binding of ferritin-EGF to the cell surface (S. Cohen, personal communication).

These observations on internalisation of EGF are probably applicable to other peptide ligands, although the probability of differences between *in vitro* and *in vivo* regulation should be noted, as should the degree of variability in the rate and extent of receptor processing in various cell types. This is illustrated by the fate of receptor-bound insulin after uptake by adipocytes, lymphocytes and hepatocytes. The specific binding of ^{125}I-insulin to adipocytes became less reversible with time, as if compartmentalised and less accessible to dissociating agents[94]. Also, the bound tracer was rapidly converted to iodotyrosyl fragments, suggesting that internalisation and processing is responsible for the degradation of much of the insulin bound to receptor sites. In contrast to the cultured lymphocyte, where translocation was minor, insulin bound to hepatocytes was progressively internalised and underwent lysosomal degradation[95]. This process must have occurred by endocytosis of the hormone–receptor complex, and would explain ligand-induced receptor loss. However, down-regulation of insulin receptors is also prominent in cultured lymphocytes, where the intracellular translocation of hormone is small in relation to the final degree of receptor loss. Given the time required for insulin-induced receptor loss in cultured lymphocytes, the rate of internalisation could be adequate to account for the receptor loss observed after several hours in the cultured cells.

Further evidence for hormone internalisation was provided by studies on the uptake and metabolism of gonadotropins in cells of the testis and ovary. The presence of gonadotropin binding sites in the cytoplasm of ovarian cells has been demon-

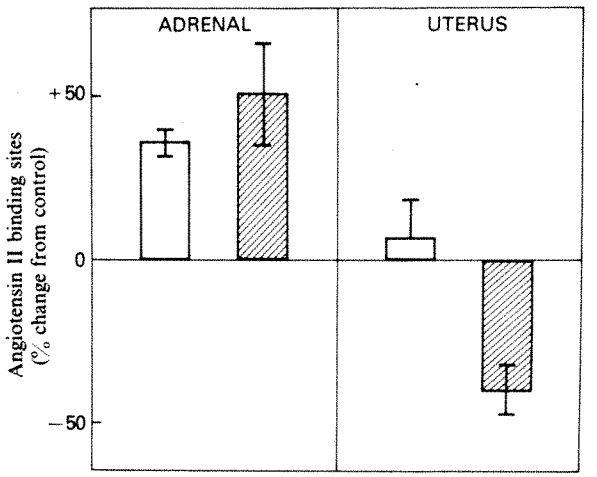

Fig. 3 The reciprocal effects of low sodium intake on angiotensin II receptors of adrenal glomerulosa cells and uterine smooth muscle. Open column, 36-h low sodium: cross-hatched column, 7-d low sodium.

strated by immunocytochemistry and autoradiography. After *in vivo* treatment with hCG, localisation of the hormone was demonstrated in membrane, cytoplasmic and perinuclear sites, much of the hormone being within the cytoplasm[3]. More direct evidence has come from studies of the ovine corpus luteum, where significant amounts of ^{125}I-hCG were taken up within endocytic vesicles and incorporated into dense bodies, presumably lysosomes[96]. Lysosomal degradation of gonadotropins occurs in Leydig tumour cells, in which the binding and metabolism of ^{125}I-hCG was not affected by agents which alter microfilaments and microtubules[97]. In these cells, steroidogenesis is not dependent on hormone degradation, consistent with the rapidity with which binding to receptors is followed by the acute metabolic effects of the hormone. The loss of gonadotropin receptors induced by hCG in the ovary is accompanied by progressive internalisation of receptor-bound ^{125}I-hCG, and at least a proportion of the translocated radioactivity can be identified as the hormone–receptor complex after solubilisation and density gradient centrifugation[98]. Such findings have indicated that internalisation is a common sequel to hormone–receptor interaction, and is likely to be responsible for the down-regulation of surface receptors that frequently follows exposure to elevated concentrations of the homologous hormone.

Conclusions

The effects of receptor regulation on target cell function are both marked and widespread in peptide-modulated endocrine tissues. The initial phase of receptor occupancy and target cell activation is frequently followed by a period of diminished responsiveness that accompanies the presence of residual hormone on receptor sites. This corresponds to the short-term phenomenon described variously as desensitisation, tachyphylaxis or refractoriness, and is sometimes caused by temporary inactivation of adenylate cyclase. In the case of non-cyclic AMP-mediated hormones, other membrane effector systems are presumably inactivated during receptor occupancy. A general scheme of the sequence of events following hormone–receptor interaction is shown in Table 1, which presents the known and hypothetical events that follow the initial event of activation by binding of the homologous hormone to the specific membrane receptors.

In certain tissues, such as the amphibian erythrocyte, refractoriness may depend largely on such transient inactivation of receptors and adenylate cyclase, with subsequent reactivation of these membrane systems when the agonist–receptor complex dissociates. In other cells, depending on the affinity with which the ligand is bound and the rate and extent of receptor and membrane turnover, occupancy is followed by a true loss of receptor sites due to processing and internalisation of the hormone–receptor complex. The degree to which different ligands are able to decrease or increase their specific receptors must also depend on the relative rates of receptor processing and resynthesis in the respective target cells. Thus, minor loss of receptors may not be evident if the rate of receptor synthesis or activation is markedly increased by the initial hormonal stimulus, a mechanism that could account for the increased receptor number in certain cells exposed to high hormone levels. In the more general case, where marked loss of receptor sites follows hormone binding, it is likely that peptide hormone receptors are not necessarily vacated and re-utilised, but may be occupied only once and then degraded or processed.

The fate of processed hormone–receptor complexes, and perhaps some of the adjacent free receptors, probably depends on internalisation and lysosomal degradation. The initial event involves incorporation of both hormone and receptors into endocytic vesicles probably through a coated pit mechanism, with subsequent rapid metabolism of the hormone. Whether recycling of membrane components occurs during receptor regeneration is unclear, but this seems unlikely given the prolonged time needed for recovery of receptors in most tissues. The biological role of hormone–receptor internalisation and degradation remains uncertain, other than as a mechanism for terminating hormone action initiated by tightly bound ligands. These processes may also protect target cells from prolonged or excessive stimulation, and could exert long-term effects on target cell growth and differentiation.

The Tieschitz, H3, chondritic meteorite apparently formed as part of a parent-body by the accretion of both molten and solid materials with a mean temperature of 800 ± 100 °C, followed by slow cooling to lower temperatures. Our data argue against the currently accepted model of equilibration with a cooling gas of solar composition.

KNOWLEDGE of the conditions of planetary formation in the Solar System is largely obtained from meteorite studies. Of particular interest are the unequilibrated chondrites, rare meteorites in which disequilibrium mineral assemblages have survived because they were unaffected by the period of thermal metamorphism which produced crystallisation in most chondrites. Tieschitz fell in Czechoslovakia in 1878. It belongs to the high iron, H, group of chondrites, has prominent chondrules many of which contain glass, and its olivines and pyroxenes have wide ranges of composition. Tieschitz is, therefore, an unequilibrated chondrite *par excellence*[1,2]. All chondrites contain small amounts of the volatile metals Tl, Bi and In, whose presence is explained either by the accretion of various proportions of high temperature and low temperature fractions, followed by closed system metamorphism[3–5], or else by total accretion at low temperature followed by open system metamorphism[6,7]. In either case, models are based on the condensation of volatiles from a gas of solar composition. Recently, Ikrammudin *et al.*[8] heated aliquots of powdered Tieschitz for a week at different temperatures and under a low pressure of hydrogen. Ten elements were determined in each aliquot and elemental loss from unheated material was calculated for each temperature. It was concluded that, in the experimental conditions, open system metamorphism of Tieschitz starting material could not account for trace elemental abundances in more metamorphosed chondrites.

We have carried out some 600 analyses of Tieschitz silicate minerals, glasses or fine-grained intergrowths, sulphide and metal. One of us (J.R.A.) has used high-voltage electron microscopy to study textures and identify minerals in the fine-grained matrix. Mobility during accretion of nepheline-normative liquids allows us to use data from experimental petrology to constrain accretion temperatures. Finally, we discuss the implication that, because of the presence of troilite, the Tieschitz assemblage was not in equilibrium with a gas of solar composition[9,10].

Results

The meteorite comprises millimetre fragments and spherical chondrules of silicate, all of which have opaque rims, together with smaller, near spherical bodies of metal or metal plus troilite. Outside the opaque rims, between fragments and chondrules, there may be a channel of variable width filled by transparent material; this has been termed by Christophe-Michel-Levy[11] "white matrix", in contrast to the "black matrix" of the opaque rims. A few of the fragments clearly represent pieces broken from solid, chemically fractionated, pre-existing rock. For example, one fragment is composed of a granular intergrowth of pigeonite, olivine (Fo_{86}), and crystalline plagioclase (An_{78-68}); this rock is a norite. However, other angular fragments have minerals of variable composition set in devitrifying glass and were apparently broken from solid chondrules or pre-existing rock.

Most chondrules exhibit quench textures. Olivine and/or pyroxene crystals are associated either with clear glass or with fine-grained turbid material which is interpreted as devitrified glass. Some chondrules contain blobs of metal or sulphide or both. Most olivines and pyroxenes are zoned. In all cases zoning is normal, olivines tending towards iron enrichment in rims and pyroxenes tending towards iron and/or calcium enrichment. In

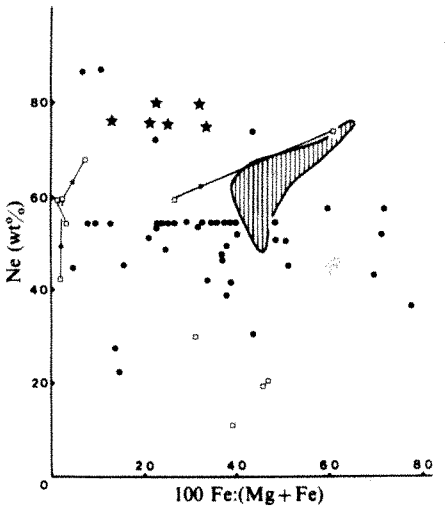

Fig. 1 'Nepheline' (wt %) versus 100 Fe:(Fe+Mg) (atomic), in Tieschitz glasses and fine-grained matrices. 'Nepheline' is the figure obtained from casting the bulk analysis in the SiO_2, nepheline, kalsilite residual system (see Fig. 2). Shaded area represents the white matrix. ●, Chondrule glasses and matrices. ★, Lilac glass from dumb-bell-shaped chondrule. □, Inclusions in olivine; tie lines link those from the same host crystal. A row of solid circles has normative feldspar close to albite, which projects at 54% Ne.

composition, olivine cores in 30 chondrules or rock fragments range from pure forsterite to Fo_{60}. Seven isolated olivines from the matrix between chondrules are either Fo_{80} or about Fo_{60}; in addition one matrix olivine is Fo_{90}.

Glasses or turbid mesostasis in 30 chondrules or chondrule fragments were analysed. Compositions vary from chondrule to chondrule, and, to some extent, within chondrules. The atomic 100 Fe: (Fe + Mg) ratio ranges from 4 to 80 (Fig. 1) and the lime content (wt) from about 1% to over 14%. Analyses were performed using an energy dispersive system on an electron microprobe. Usually, the energy spectrum was integrated over 80 s on a single point, but in some cases a defocused beam was used and in others the spectrum was integrated for four 20-s counts each on a different spot. There was no evidence of loss of alkalis, and glasses apparently did not decompose under electron bombardment; totals were always between 96 and 102%. Figure 2 shows the analyses cast in the silica–nepheline ($NaAlSiO_4$)–kalsilite ($KAlSiO_4$) ternary diagram (wt), after assigning SiO_2 to the various normative mafic and calcium-bearing minerals. All interstitial materials within chondrules plot close to, or on, the SiO_2-nepheline join, because of their lack of K_2O. However, in some chondrules, phenocrysts of olivine contain inclusions, some of which have over 1.5% K_2O. In one pair of inclusions and one triplet, each from a single olivine, a decrease in K_2O is accompanied by an increase in the iron-to-magnesium ratio. This negative correlation of the K_2O and the iron-to-magnesium ratio is contrary to the normal consequences of igneous fractionation. Hence we believe that, in some chondrules, loss of potassium by volatilisation took place. Early, potassium-rich liquids were preserved by their complete enclosure in olivine. On the ternary plot, about half of the chondrule matrices project at the albite composition; in this respect many Tieschitz chondrules resemble those of Bjurböle[12].

A small proportion of the chondrules have non-spherical shapes which were determined, after accretion, by the impingement of adjacent objects on them. At least some of these mis-shapen chondrules were undoubtedly still partially molten during aggregation. One encountered in the present study is roughly dumb-bell-shaped (Fig. 3) and has skeletal crystals of olivine set in turbid, lilac-coloured glass. The olivines are close to pure forsterite, but the glass shows some iron enrichment; this latter is highly nepheline-normative and contains up to about 0.5 wt % K_2O; analyses gave totals from 98 to 102%. Texturally it seems evident that this material was plastic when incorporated into the meteorite parent. Subsequent compaction by other, more solid objects caused it to adjust by flow to fit the irregular space available. A second mis-shapen chondrule (Fig. 4) is micro-crystalline. It too, was clearly plastic or molten when accreted. Subsequent deformation caused the dark rim to rupture as part of the contents squeezed out. The micro-crystalline material is potassium-poor, with variable undersaturation in silica. The 100 Fe:(Fe+Mg) atomic ratio also varies from 45 to 70. Some decomposition occurred under the electron beam and totals were rather low, with a maximum of 97.5; we suspect that the fine-grained material may be slightly hydrated, as the surface is highly polished.

White matrix occupies some narrow, interstitial areas outside the dark rims of chondrules and clasts[11]. In thin section, between crossed polars, it consists of a fine-grained intergrowth of crystals of low birefringence; electron diffraction indicates that nepheline is common and some plagioclase is present. Only broken grains were found in the electron microscope study, but some large (>10 μm) fragile nepheline fragments were probably generated close to their present location. A polished surface in reflected light confirms that white matrix is composed of angular to rounded fragments, the largest observed being close to 20 μm across. The bulk compositions of compact white matrix (Fig. 2) indicate the same nepheline plus plagioclase mineralogy. Textural evidence (Fig. 5) shows that cohesive masses of this white matrix were mobile during the accretion of the chondrite. Analysis totals for white matrix are low (80–97%; compare ref. 11), because it does not become highly polished (due to its fractured nature?), and decomposes in the electron beam. Nevertheless, compared with chondrules, our data (analyses of 25 locations) establish a striking consistency of composition, throughout a 2.5-cm^2 thin section (Figs 1, 2). White matrix usually has 8–10% Na_2O, about 2% CaO and 100 Fe:(Fe+Mg) of 40–60.

Discussion

It seems that some constituents of Tieschitz were molten or plastic after aggregation. Experimental petrology may be used to constrain the conditions in which flow could have taken place. We can then outline some of the consequences imposed by these conditions for the cooling history of the meteorite.

There are two temperature minima on the silica–nepheline join, separated by the albite ($NaAlSi_3O_8$) composition (Fig. 2). On cooling, liquids with compositions between albite and silica crystallise one or other phase, depending on initial liquid composition. This drives the composition of the residual liquid towards the minimum at which both phases crystallise together at 1,062 °C (for the dry system) until completely solidified[13]. For

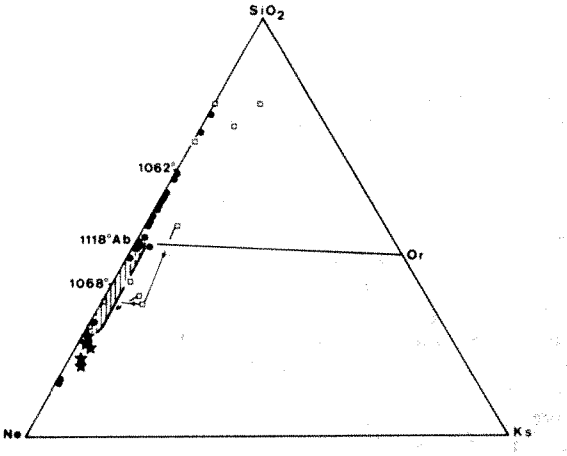

Fig. 2 Residual system SiO_2-nepheline ($NaAlSiO_4$)–kalsilite ($KAlSiO_4$) (wt). Symbols as in Fig. 1. The melting point of albite, and minima on the SiO_2–nepheline join are in °C.

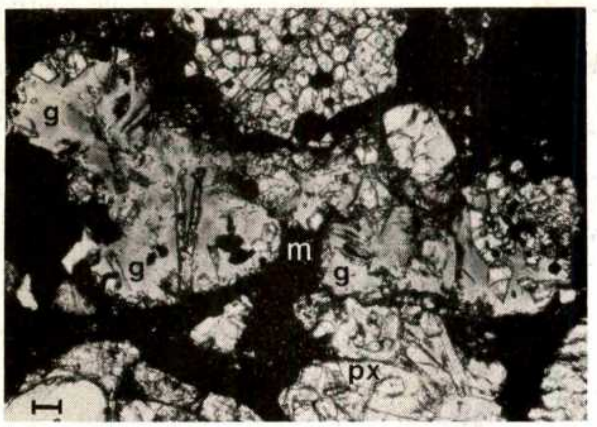

Fig. 3 Dumb-bell-shaped chondrule. m, Metal grain in dark matrix; g, lilac-coloured glass, partly turbid; px, porphyritic pyroxene chondrule. Although some brittle fracturing occurred above and to the right of 'm', the two long, fragile olivine crystals between 'g' and 'm' (lower left of centre) are undeformed and grew *in situ* from the melt after the shape of the chondrule had been determined. Scale bar, 0.05 mm.

liquids with composition between albite and nepheline, crystallisation of one of these phases drives the liquid towards a minimum at 1,068 °C. Because white matrix compositions straddle this second minimum, they probably represent solidified, fractionated liquids. Between the two minima is a thermal barrier which cannot be crossed by a crystallising liquid at low pressure. We interpret the white matrix as being representative of different liquids which tended towards the 1,068 °C minimum by crystal-liquid fractionation. On the other hand, many chondrule liquids are oversaturated with silica and so tended to fractionate towards the 1,062 °C minimum. But these liquids are more viscous than the undersaturated ones and hence were not mobile during accretion.

We envisage that white matrix liquids were available in small quantity distributed among the aggregating mass of chondrules, clasts, metal, sulphide and mineral fragments. These liquids show a genetic relationship with nepheline-normative chondrules. Initially, white matrix must have been sufficiently mobile for it to have flowed for distances of a few mm along interchondrule channels up to 50 μm wide. The question then arises in what conditions could the white matrix have been mobile? One measured composition (SiO_2 56.2% (wt); TiO_2 0.50; Al_2O_3 18.3; FeO 4.75; MgO 3.32; CaO 3.86; Na_2O 8.9; K_2O 0.40; sum 96.23), with 1 wt % H_2O, has a calculated minimum viscosity of 10^4 P at 900 °C (H. Pinkerton and L. Wilson, personal communication, and refs 14, 15). Water is present in Tieschitz[1]; 1% water in white matrix lowers the viscosity by a factor of 2–5, and slightly lowers the liquidius temperature. The calculated viscosity is comparable to that of rhyolite liquids during eruption; their viscosities are so high that it is surprisng that they can be erupted at all. A liquid of 10^4 P requires a pressure gradient of about 50 kbar cm^{-1} to cause it to flow for 5 mm along a channel 25–50 μm wide. The pressure required is greatly in excess of the measured compressive strengths of meteorites[16], hence injection of white matrix as a liquid at 900 °C or less, is impossible. The calculated yield strength of liquid white matrix at 900 °C is 10^8 c.g.s. units[15]. Emplacement as a solidifying liquid, by comminution, requires a pressure gradient of 20 kbar cm^{-1} which is still unacceptably high. Crystallisation would exacerbate the situation. The Tieschitz meteorite is, in fact, noted for the absence of significant deformation effects[11]. We must therefore assume that white matrix was emplaced in a fluid state which requires a temperature above 900 °C. Now, a 100-μm thick film of silicate liquid, in a vacuum, would solidify from 1,100 °C in microseconds. So, if Tieschitz accreted mainly as chondrules, clasts and metal at 170 °C (~455 K, for the two-component model championed by Anders and co-workers[17]), interspersed with a few per cent of molten chondrules and white matrix liquid, the melts would have solidified immediately.

Our only solution to this problem seems to be that hot, liquid, white matrix and plastic chondrules were accreted with chondrules, clasts, metal and sulphide at a cooler, though still high, ambient temperature. We now try to constrain this temperature. Chondrules show the effects of rapid quenching and we observe gross compositional heterogeneities between olivine and pyroxene crystals. The main, low-calcium pyroxene is the twinned monoclinic variety. There is also pigeonite exsolved on a very fine scale (~10 nm) in crystals with a higher lime content. All these features indicate rapid cooling to around 800 °C, or less. In addition, low-calcium pyroxenes with a variety of iron contents have remained unattacked by engulfing white matrix which, being nepheline-normative, must have been strongly out of equilibrium with this pyroxene. Either the chondrules and debris came together at about 800 °C, with residual alkaline liquids at higher temperature and still crystallising matrix olivine (Fo_{60-80}), or accretion took place with all the components at temperatures above 800 °C, during rapid cooling. In either case we propose that the effective accretion temperature was 800 °C, this being the highest temperature that can plausibly be invoked for the end of rapid cooling of the mafic silicates.

An upper limit to the accretion temperature is fixed at 988 °C by the minimum in the Fe–FeS system[18]. The addition of nickel lowers the minimum, but precise data are not available. If the ambient temperature during accretion of Tieschitz had exceeded 900 °C, then metal plus sulphide should have been mobilised[19], and squeezed between the chondrules. As this is not observed, we can set the maximum temperature during accretion at 900 °C. Because the Fe–FeS eutectic temperature is well below the solidus on the nepheline–albite join, we can eliminate metamorphic reheating as a cause of white matrix mobility. Had the Tieschitz assemblage aggregated cold, subsequent heating would have caused the flow of metal plus sulphide liquids when the eutectic was reached at above 900 °C. A further increase of over 100 °C would have been required to produce melting in the white matrix. We have observed no textural evidence of metamorphism except for compaction in some chondritic clasts. In them the same unequilibrated silicates occur as in the meteorite as a whole. A lower limit to the accretion temperature may be established as follows: metal in Tieschitz occurs in a number of textural associations. Nickel distribution in the metal grains was measured using a con-

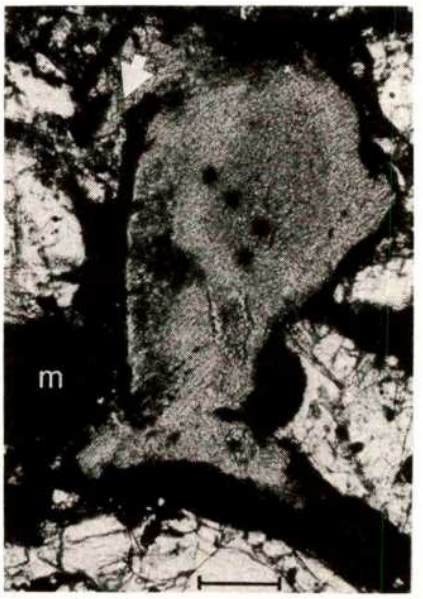

Fig. 4 Mis-shapen chondrule. m, Metal. Compression from left and right caused the dark matrix surrounding the chondrule to rupture, forcing the contents out (see arrow). The four dark spots are 'probe' burns. Scale bar, 0.05 mm.

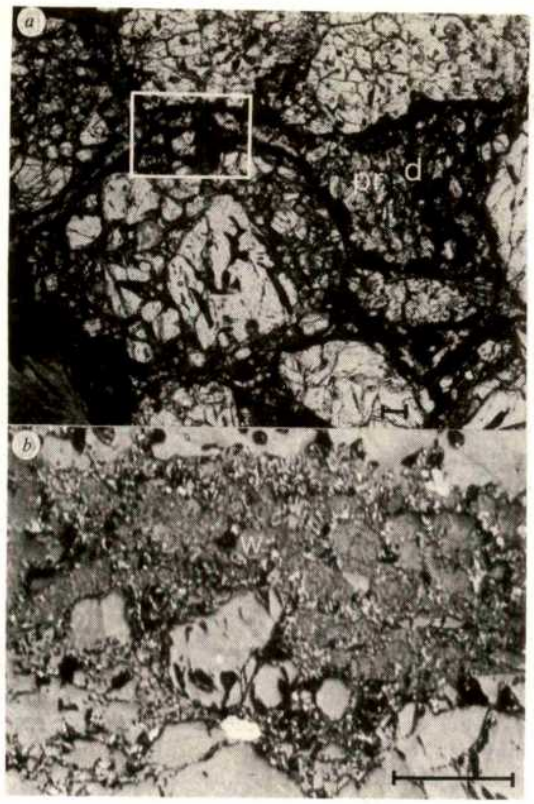

Fig. 5 White matrix: *a*, transmitted light; *b*, reflected light. The field of *b* is the rectangular outline in *a*. In the top left of *a* white matrix fills channels between three chondrules outlined by dark matrix. To the right, one channel with white matrix runs into a pyroxene-rich area pr, which is delimited on the right by dark matrix *d*. *b* Illustrates the block-like nature of white matrix, one piece of which is marked (w). Metal is brilliant white. Vermicular, light lines are cracks outlined by adhering carbon coat which was cleaned from most of the surface. Scale bars, 0.05 mm.

ventional, wavelength-dispersive microprobe technique. Both kamacite and taenite grains show a relationship between size and central nickel content, indicating that all metal cooled through about 500 °C *in situ*, thus confirming the conclusion of Wood[20]. The cooling cycle must have begun near 700 °C, the temperature at which bulk Tieschitz metal (11.8% Ni, ref. 21) would enter the $(\alpha+\gamma)$ field, if the effect of undercooling is neglected. Thus the lower limit to accretion temperature is fixed at 700 °C. We can therefore conclude that Tieschitz effectively accreted at (800 ± 100) °C.

Christophe-Michel-Levy argued that white matrix represents part of the contents of chondrules which had been leached out and redeposited by a fluid phase[11]. However, it seems impossible to mobilise preferentially a silica undersaturated component, white matrix, without attacking low-calcium pyroxene. (For example, in the terrestrial, aqueous environment low-calcium pyroxene tends to be very unstable.) Moreover, the presence of water could not have been responsible for the deformation of the chondrule in Fig. 4, because the effect of water in reducing the viscosity of the chondrule liquid would have been much less than the effect of falling temperature in increasing it.

Accretion of an unequilibrated ordinary chondrite at 800 °C has several implications. This temperature is higher than that of the reaction of H_2S gas with metal to form troilite plus hydrogen from a gas of solar composition[9,10]. We must then assume that any gas in equilibrium with the accreting components of Tieschitz was depleted in hydrogen relative to a gas of solar composition[10]. Obviously, this can be overcome by *ad hoc* assumptions such as rapid formation of chondrules and metal plus sulphide during, for example, an impact event—but this must be a non-equilibrium reaction. In contrast, the story in the Tieschitz metal supports equilibration and slow cooling over temperatures around 500 °C, which is still above the temperature at which troilite can form by reaction from a gas of solar composition. Following Herndon and Suess[10], our findings indicate that the Tieschitz assemblage was probably associated with a gas depleted in hydrogen by a factor of 100 or more relative to solar composition.

These implications may be taken further. In the two-component model, or variations of it, the temperature of accretion of chondrites has been defined by the estimated temperature at which a low temperature, volatile-rich component ceased to equilibrate with a cooling gas of solar composition. Larimer's estimate for Tieschitz is ≤445 K (170 °C)[17], it depends, among other things, on gas composition. A temperature of 170 °C may be reconciled with our estimate of 800 °C for the accretion temperature if it is assumed that the highly porous Tieschitz[11,22] continued to equilibrate with gas during slow cooling. During this stage of the meteorite's history the partition of Ni between kamacite and taenite occurred. In addition the meteorite received its complement of the volatile metals Tl, Bi, In and Pb by condensation from the coexisting gas. Such a mechanism has been suggested for the L3 chondrite, Khohar, on the basis of Bi distribution between metal grains[23]. Where did the volatile metals go? They probably condensed into any suitable substrate, such as dark matrix around chondrules and clasts. Dark rims (=matrix) to chondrules and clasts were, in some instances at least, picked up when chondrules were liquid. We cannot, therefore, assume that the volatiles are present in the dark rim material, or that a low temperature carrier of volatiles existed and was available during accretion of solids. There is some evidence that in ordinary chondrites Pb is not highly concentrated in the sulphide[23,24], as would be expected for equilibrium condensation from a gas with free access to sulphide grains. Furthermore, the existence of troilite in a high temperature mineral assemblage indicates that thermodynamic modelling of condensation must be extended to embrace non-solar compositions of gas. Also, a purely hydrogen atmosphere[8] is probably inappropriate for experimental heating of chondrites.

Finally, the presence of dark rims around norite clasts indicates that at least one period of fractionation preceded the accretion of Tieschitz. Perhaps ordinary chondrites are not really primitive objects, or maybe depletion in hydrogen occurred due to kinetic effects in the atmosphere of a growing planet which had received material from the break-up of an already differentiated body. This argument has already been put forward[25].

J.R.A. thanks Dr M. H. Loretto of the University of Birmingham for the use of the high voltage electron microscope. We thank Drs H. Pinkerton and L. Wilson for calculations and discussion, and the NERC for support.

Morphology and intracortical projections of functionally characterised neurones in the cat visual cortex

Charles D. Gilbert & Torsten N. Wiesel

Department of Neurobiology, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02115

The neuronal structure and connectivity underlying receptive field organisation of cells in the cat visual cortex have been investigated. Intracellular recordings were made using a micropipette filled with a histochemical marker, which was injected into the cells after their receptive fields had been characterised. This allowed visualisation of the dendritic and axonal arborisations of functionally identified neurones

CONSIDERABLE insight into the stages of visual information processing has been obtained from analysis of single cell responses to patterned light stimulation. This approach revealed that cells in the visual cortex respond optimally to specific stimuli, such as line segments of given orientation and length[1,2], and that neurones differ in their specificity. Cortical neurones also show great morphological diversity[3-7], suggesting that there may be a correlation between the function of a cell and its structure. Another feature of cortical organisation is that cells are segregated into layers, and in each layer the cells have distinct size, shape and packing density. This lamination has long been thought to be important in cortical function[8-10]. The layers differ further in the receptive field properties of the cells within them[2,11-13], in the inputs that they receive[14-17] and in the sites to which their cells project[18-22]. This information was derived from extracellular recording and anotomical tracing, but now intracellular marking techniques, first used in the visual cortex by Kelly and Van Essen[23], can extend these findings by showing the detailed intracortical wiring of cells with known response properties.

In this study we have been able to trace the intracortical projections of functionally identified neurones in different layers by intracellular injection of the enzyme horseradish peroxidase (HRP)[24,25]. Comparison of the receptive field properties of marked cells with those of cells in the layers to which they project provides evidence for the manner in which receptive fields are constructed.

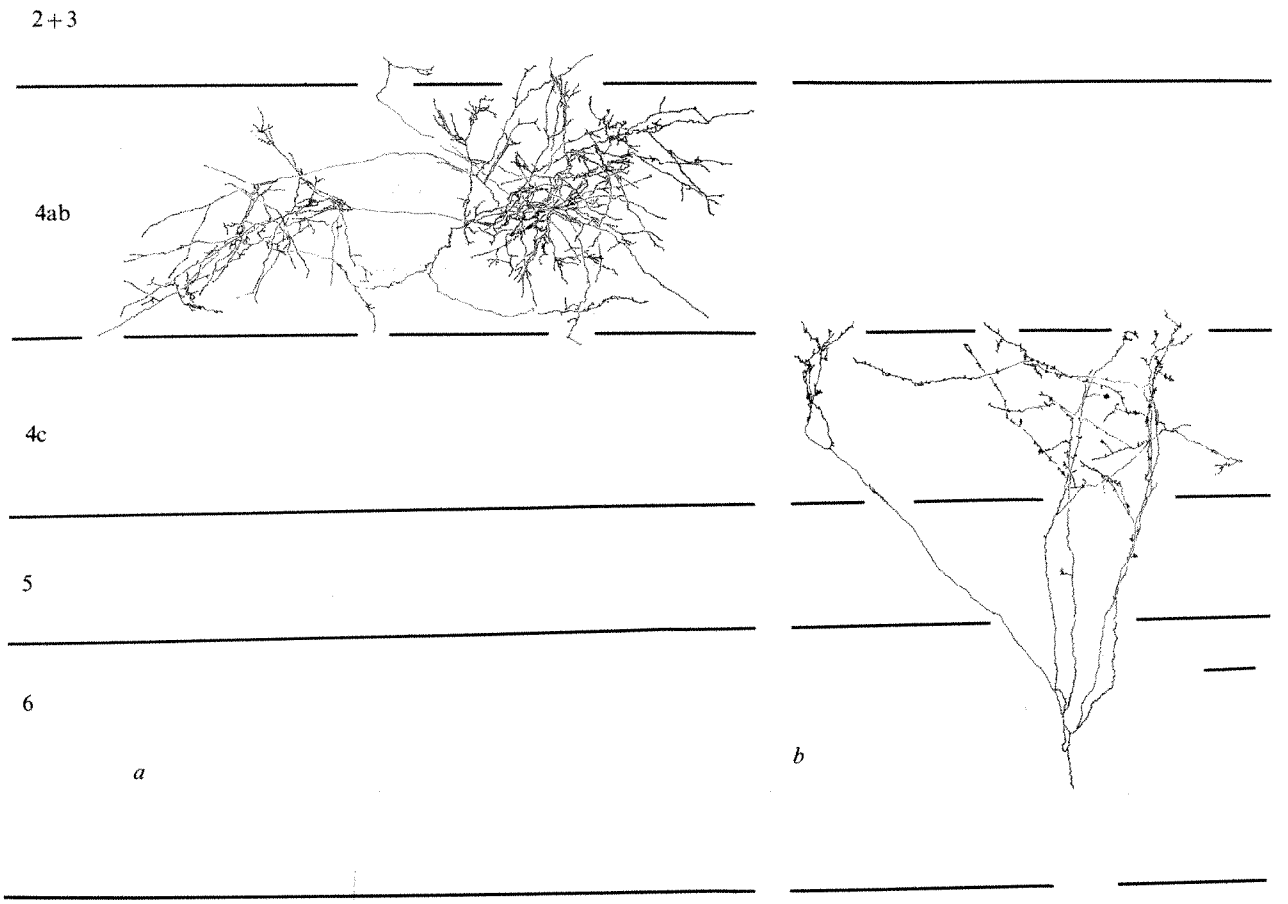

Fig. 1 Two afferents from the lateral geniculate nucleus, injected within the cortex. Was an off-centre Y-cell (centre size 1.5°, located 5° from the area centralis), and ramified entirely within layer 4ab. Was an off-centre X-cell (centre size 1°, located 3° from the area centralis), which ramified entirely within layer 4c. Scale bar, 100 μm.

Functional characterisation and labelling of visual cortical neurones

Recordings were made in cats maintained on sodium thiopental anaesthesia, paralysed with succinylcholine and artificially respirated. The animals' electrocardiogram, electroencephalogram, temperature and expired CO_2 concentration were monitored. A small hole was drilled in the skull above the visual cortex, and the dura and pia were opened. Half-micrometre bevelled-tip electrodes were filled with a solution of 4% HRP (Boehringer–Mannheim, grade I) in 0.2 M KAc, *p*H 7.6. After penetration of the brain surface with the electrode, the hole in the skull was filled with agar to reduce pulsations. The electrodes were advanced through the brain with a stepping microdrive (Transvertex) until a cell or process was penetrated, as indicated by a sudden change in the resting potential, the appearance of large action potentials and often synaptic activity. The receptive field properties of the cells were determined using either a hand-held projector or an optical bench.

The cells were injected with HRP either by pulses of pressure ranging from 0.5 to 5 atm or by pulses of positive current ranging from 1 to 2 nA in a 4 ms-on/4 ms-off duty cycle. At the end of the experiment each animal was perfused with a short buffer rinse followed by a long perfusion with 2% glutaraldehyde in the same buffer. After the brain was blocked, 150-μm coronal sections were cut on a Vibratome (Oxford Instruments), and then treated with a combination of the diaminobutyric acid reaction at acid *p*H[26] and cobalt intensification[27]. The injected cells were reconstructed from serial sections by using a microscope equipped with a drawing tube. Subsequently, the sections were counterstained with cresyl violet, and the laminar position of cells and their processes were determined using the criteria of Otsuka and Hassler[28]. Table 1 lists the cells in each layer that we have injected to date.

Cortical afferents

Different morphological and physiological classes of retinal ganglion and geniculate cells are known to exist[29–32]. Chief among these are the X- and Y-cells. These are defined by the linearity of spatial summation within their receptive fields[29], and also have been found to differ in their firing properties and axon conduction velocities[30,33,34]. The dorsal geniculate laminae, which contain a mixture of X- and Y-cells[35], project to layers 4 and 6 in the visual cortex[16,17].

In this study we were able to penetrate and inject individual axons coming from the lateral geniculate nucleus either before or after they enter the cortex. We used the criteria of spatial summation to classify X- and Y-afferents[29,36]. A reconstruction of each type is shown in Fig. 1. The Y-afferent (Fig. 1*a*) had off-centre/on-surround organisation, showed nonlinear summation, had a relatively large field centre (1.5°) and gave a transient response to a stationary flashing spot of light. It ended in layer 4ab in a rich arbor distributed in two patches separated by a terminal-free gap. The patches presumably correspond to ocular dominance columns driven by one eye, and the intervening gap to the column driven by the opposite eye[15,37] Some of the injected Y-afferents also sent collaterals to the upper half of layer 6.

In contrast to the afferents showing nonlinear summation, the X-afferent arborised entirely within layer 4c (Fig. 1*b*). No afferents were found to arborise in both sublayers of layer 4. This demonstrates, in agreement with Ferster and Levay[38], that the dorsal geniculate layers, which contain a mixture of at least two principal cell types, keep the input from the two types segregated on their arrival in the cortex.

Layer 4 cells

Cells in layer 4 lie in the terminal field of the geniculate afferents, and consequently represent the first level of processing in the cortex. Extracellular recordings show that the overwhelming majority of the cells in layer 4 have simple receptive fields[1,11,23], as defined by Hubel and T.N.W.[37]. In addition to their specificity for stimulus orientation, simple cells can show a reduction in response to slits longer than the receptive field[11,39,40]. This property, known as end-inhibition, makes cells optimally responsive to orientated lines of a defined length. Figure 2*a* shows an example of a simple cell in layer 4ab. It was a spiny stellate cell; the axon branched several times soon after leaving the soma, with a number of collaterals innervating in layer 4ab and then giving off a rich terminal arborisation in layer 2+3. The axon proceeded out of the cortex into the white matter, sending a few collaterals into the lower layers in its downward course. This general projection pattern was seen for all injected 4ab spiny cells and has also been observed with Golgi stains[3–6]. The horizontal extent of the axonal arborisation was much larger than that of the dendritic arborisation. This divergence could produce a further mixing in the input from the two eyes onto layer 2+3 cells, and could account for the higher proportion of binocularly driven cells found in that layer than in layer 4 (refs 1, 11).

Only two cells have been injected in layer 4c, one a small spiny stellate cell and the other a smooth stellate cell (Fig. 2*b*). They had very similar receptive field properties; both had simple receptive fields with on-centres, which were much smaller than those of the layer 4ab simple cells. The smooth stellate cell's axon ramified extensively throughout layer 4. The axon of the spiny stellate cell gave off many collaterals, some remaining within layer 4c and others extending to layer 4ab. Although the cell's axon was restricted to layer 4 (which is consistent with Golgi findings[5]), the existence of complex cells with very small receptive fields in layer 2+3 (refs 1, 11) leads us to expect that there should be other layer 4c cells with projections to that layer.

Layer 2+3 cells

The predominant intracortical projection from layer 4 seems to be to layer 2+3, which then represents the second level of cortical processing. Layer 2+3 almost exclusively contains complex cells[1,11]. They are orientation selective, but differ from simple cells in having uniform receptive fields not divisible into separate on- and off-subregions and in responding continuously as a slit of light is moved across their fields[1,11,41]. Like simple cells, they can be directional and end-inhibited. For complex cells, specificity for orientation and length is maintained, but compared with simple cells they have gained some freedom in the precise position of the stimulus along the movement axis[1].

A complex cell with a small receptive field (1°×1°), showing no end-inhibition, is shown in Fig. 3. It was a pyramidal cell located in the upper part of layer 2+3. The basal dendrites ramified close to the soma and the apical dendrite extended into the lower part of layer 1. Its axon branched richly in its layer of origin, both in a region adjacent to the cell's dendritic field and in a region rather more distant, perhaps to a column of cells with the same orientation preference. The axon collaterals also extended into layer 1. The descending axon projected extensively within layer 5; this was a common feature of pyramidal cells in this layer, in agreement with degeneration[42–44] and Golgi[4,5,45] studies. The axon proceeded out of the cortex, presumably to innervate another cortical area or areas[21].

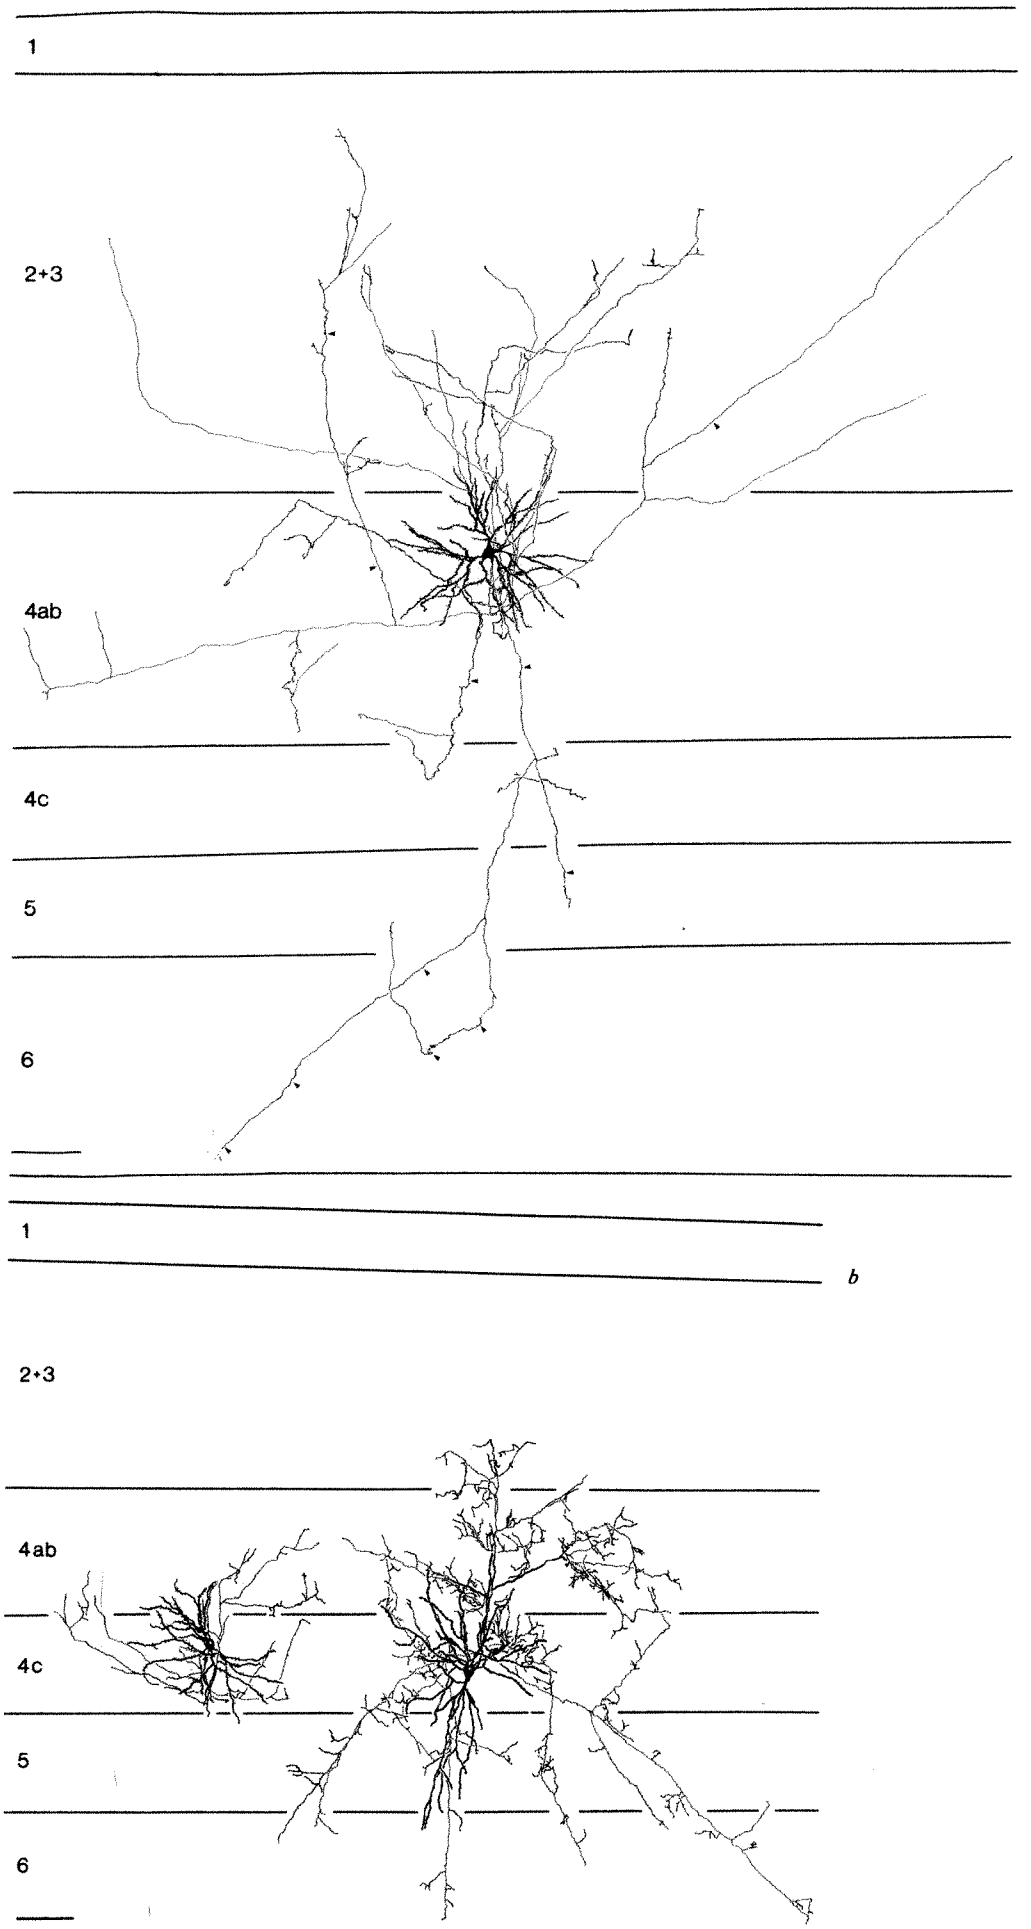

Fig. 2 *a*, A spiny stellate cell in layer 4ab having a simple receptive field with an on-centre and off-flanks, and showing no end-inhibition. The field size was $3° \times 4°$, and it was located 10° from the area centralis. The arrows indicate the positions of nodes of Ranvier. *b*, A spiny stellate cell (left) and a smooth stellate cell (right) in layer 4c. Both had simple receptive fields with on-centre and off-flanks, the spiny stellate cell showing no end-inhibition and the smooth stellate cell showing 50% end-inhibition. The size of the central on-portion of the field for both cells was $1° \times \frac{1}{2}°$, and both were located 2° from the area centralis. Because the plane of section was not perpendicular to the layers, this reconstruction makes it seem as if several sets of collaterals of the smooth stellate cell extend into layers 5 and 6, whereas in fact they remain within 4c. Scale bar, 100 μm.

Layer 5 cells

Cells in layer 5 have complex receptive fields like those in layer 2+3, but differ most notably in their large field sizes. Previous studies[11,20] have shown that within layer 5 two cell types can be distinguished: one that shows summation for increased slit length (the standard complex cell) and one that responds optimally to a small moving slit of light placed anywhere within its relatively large field, showing no summation for increased slit length (the special complex cell). Consequently, the special complex cell maintains specificity for orientation, length and direction of stimulus movement, but gains some freedom in the precise position of the stimulus along the orientation axis. Like simple and standard complex cells, the special complex cell can exhibit end-inhibition[11].

Figure 4 shows a standard complex cell in layer 5. A surprising finding was that the cell's axon sent an extensive projection to layer 6, passing 6–8 mm down the medial bank, still remaining within area 17. The cell's receptive field was $2\frac{3}{4}° \times 1\frac{3}{4}°$, and its axon spanned an area of cortex representing up to 15° of visual field. Thus, it reaches areas that deal with parts of the field of view far outside the cell's receptive field. This projection has not been seen with Golgi stains, possibly because the axon becomes myelinated soon after leaving the cell body, and would therefore not impregnate with the Golgi technique. The distribution of the axonal field as viewed from the cortical surface was long and narrow. One might expect that the overall axis of distribution of the axon would be related to the orientation axis of the cell's receptive field. The axonal distribution and orientation of this cell were consistent with this view. The apical dendrite extended up into layer 1, branching repeatedly there, and several of its processes passed just underneath the pia. The cell had a dense dendritic arbor near its cell body, with a number of processes leaving the base of the apical dendrite at the layer 4/5 border, and a set of basal dendrites extending down into the upper part of layer 6.

We have also injected special complex cells in layer 5. Their axons seemed not to project as richly to layer 6 as those of the standard complex cells, and set a large trunk out of the cortex, presumably to innervate the superior colliculus[20,21].

Layer 6 cells

Layer 6 is of special interest as it receives a direct projection from the lateral geniculate nucleus[11] and contains a mixture of simple and complex cells[1,11,23]. Its cells have unique receptive field properties, often requiring long slits for activation and showing summation with slit length up to very large values (16°)[11]. Figure 5 shows an example of a layer 6 simple cell. The basal dendrite of the cell branched in the upper part of the layer; this is interesting as the collaterals of geniculate axons in layer 6 end in the upper part of the layer (see ref. 38 and also above). Its axon projected mainly to layer 4ab, in the vicinity of its apical dendrite, which branched extensively and ended in 4ab. Other cells, both pyramidal and smooth stellate, had axonal fields that lay almost exclusively within layer 6.

Although the simple cells of layer 6 were restricted to the upper half of the layer, we found complex cells throughout the layer. The apical dendrites of these cells branched at different levels within the cortex, which is reminiscent of the pattern observed in the monkey by Lund and Boothe[45]. Like the cell in Fig. 5, they often sent collaterals primarily to layer 4, and these were restricted to either 4ab or 4c. The injected smooth stellate cell had a complex receptive field.

Intracortical pathways and receptive field construction

Although we have not yet injected all the morphological cell types found in the cortex[4], some patterns of projection have

Fig. 3 A pyramidal cell in the upper part of layer 2+3, with a complex receptive field showing no end-inhibition. The field size was 1°×1°, and it was located 4° from the area centralis. Scale bar, 100 μm.

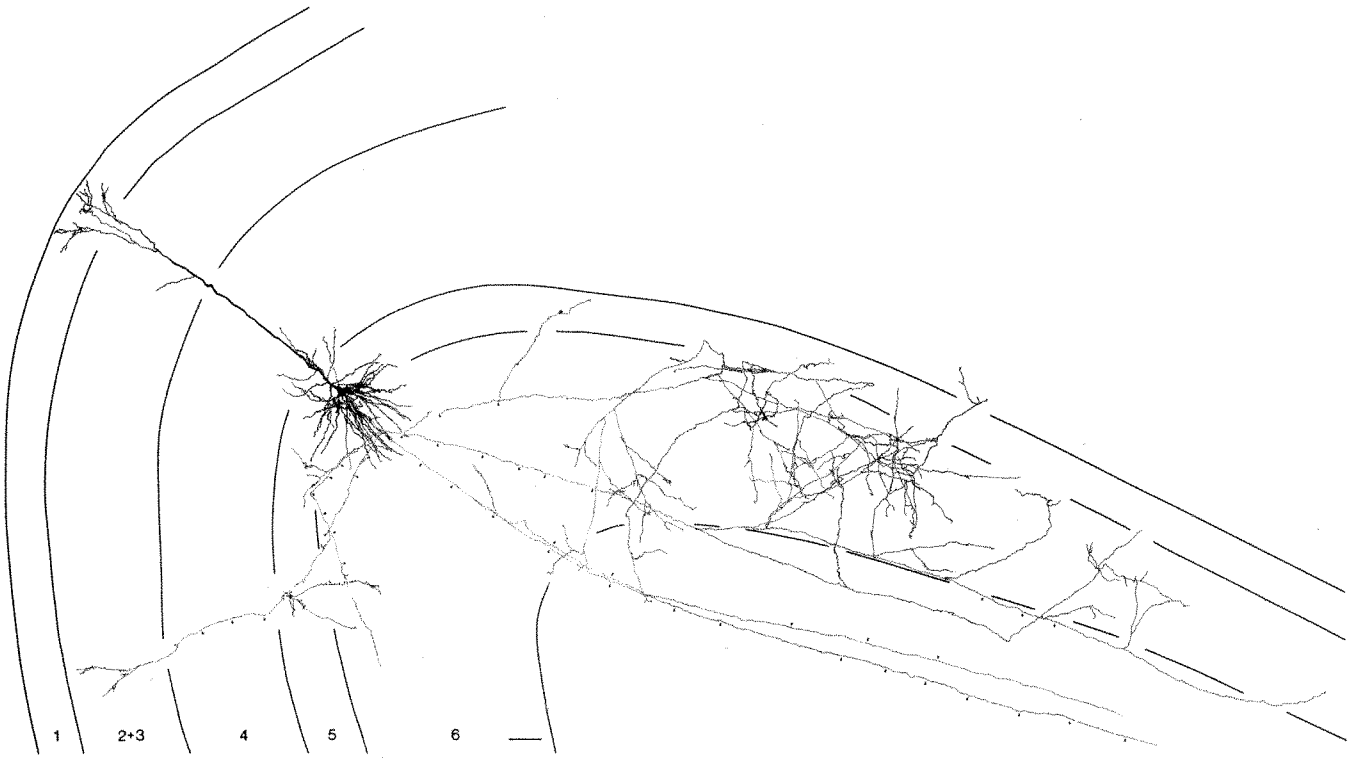

Fig. 4 A pyramidal cell in layer 5, with a standard complex receptive field showing no end-inhibition. The field size was $2\frac{3}{4}° \times 1\frac{3}{4}°$, and it was located on the area centralis. The branches of the apical dendrite within layer 1 all run quite close to the pia, but this is not apparent due to the plane of the section relative to the cortical layers. Scale bar, 100 μm.

emerged from our present catalogue of injected cells. The predominant stages of information processing in the cortex seem to be as follows: the major geniculate input to the cortex arrives in layer 4, with the X-input and the Y-input arriving separately in layers 4c and 4ab. Both inputs also project to the upper half of layer 6. From layer 4 the sequence of processing continues to the upper layers, from the upper layers to layer 5, and from layer 5 to layer 6. Layer 6 then sends output back into layer 4. The cortex is tapped for output to other regions at several stages: cortical areas from layer 2 + 3, superior colliculus from layer 5, and lateral geniculate nucleus from layer 6. Also, the spread seen in the horizontal axonal projections (Fig. 4) extends far beyond that expected from previous studies using the Golgi technique[3–6].

This pattern enabled us to form hypotheses as to the manner in which receptive fields are constructed within the cortex. As originally suggested by Hubel and T.N.W.[46], simple receptive fields are constructed from the fields of lateral geniculate neurones, as simple cells are the predominant class in layer 4, the major geniculate afferent zone. The correspondence between simple receptive field type and geniculate input is also seen for the cells that lie in the upper part of layer 6. Although they share the same general receptive field type, cells in layer 4c have smaller fields than those in 4ab. This difference is consistent with the two features of the geniculate input to layer 4—the X-afferents have smaller receptive fields than the Y-afferents, and the 4ab afferents have a much wider terminal arborisation than the 4c afferents[38]. Although the receptive fields of the injected 4c cells were quite similar, spiny cells are thought to be excitatory and smooth cells inhibitory. These presumptions are based on both their synaptic morphology and transmitter neurochemistry[47–49].

The superficial layer complex cells receive their input from the layer 4 simple cells. As cells in layer 4ab project to layer 2 + 3, and as, except for the bottom of layer 3, the geniculate does not project to this layer, it is likely that the receptive fields of cells in the upper layers are generated primarily by input from layer 4.

The layer 5 complex cells may form their fields from the concatenation of the fields of the superficial complex cells, as suggested by the extensive projection from the layer 2 + 3 cells into layer 5. The lateral spread of this projection can account for the increase in receptive field size from the superficial layers to layer 5. Because their apical dendrites pass through geniculate afferent zones, the layer 5 complex cells may also receive geniculate input. Evidence from serial electron microscopic reconstructions suggests, however, that they do not[50]. We do not know what are the differences in the inputs to standard and special complex cells which account for their differences in receptive field properties.

The substantial horizontal traverse of the layer 5 axon in layer 6 is an intriguing feature, as the layer 6 cells have very long receptive fields, showing summation for increased slit length up to very large values, some reaching 16° or more[11]. We have seen no other inputs to layer 6 or intrinsic connections within layer 6 that can account for this receptive field property; the input to layer 6 from the lateral geniculate nucleus is, if anything, more restricted than the geniculate input to layer 4 (refs 17, 38). Also, none of the cells within layer 6 that we have injected thus far have axons that ramify within the layer over nearly as large an area as do the axons from the layer 5 cells. This hypothesis requires us to account for elongation in both simple and complex fields in layer 6 despite the fact that the input from layer 5 is exclusively complex. The simple fields may be produced by an interaction between the geniculate input to the upper half of layer 6 and the input from layer 5.

The rich projection from layer 6 to layer 4 suggests that some properties manifested by layer 4 cells may not depend solely on convergence of geniculate input onto layer 4 cells or on connections made by those cells within the layer. It could be that, due to their intimate involvement with layer 4 through dendritic arborisation and axonal projection, the layer 6 cells have a role in producing orientation specificity, preference for direction of stimulus movement and/or end-inhibition.

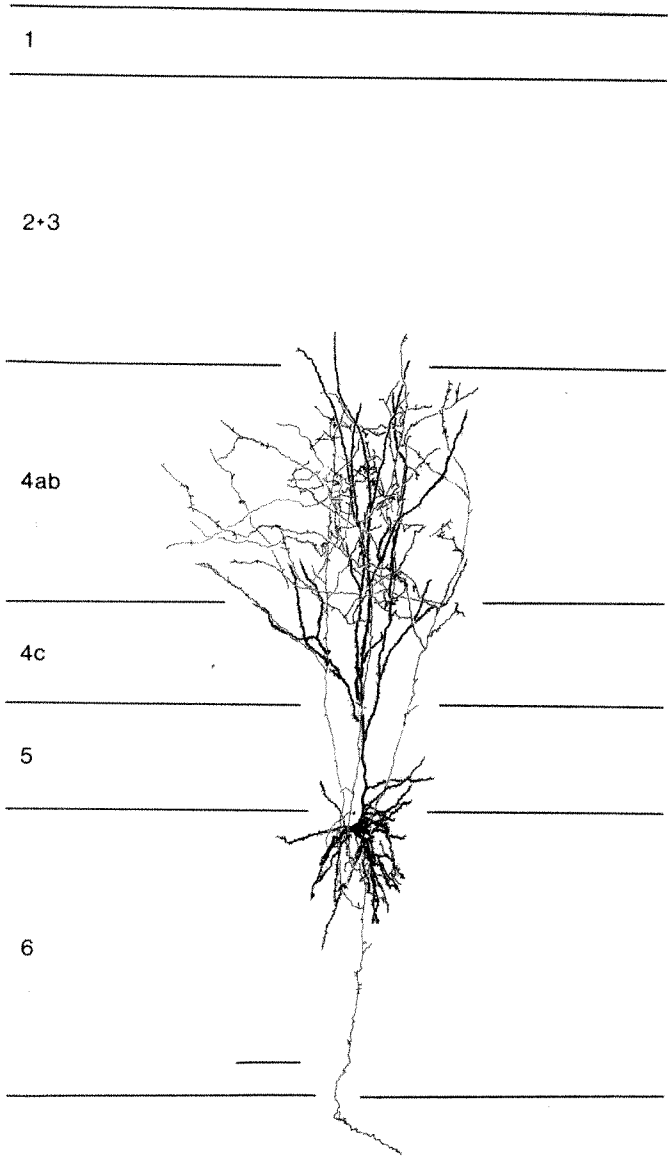

Fig. 5 A pyramidal cell in layer 6, with a simple receptive field showing the lack of end-inhibition characteristic of cells in this layer. The field size was $1\frac{1}{2}° \times 2°$, centred 4° from the area centralis. It did not show obvious summation to long slits and may represent a population of layer 6 cells with shorter fields. Scale bar, 100 μm.

Dendritic morphology and receptive field construction

Several issues are raised in considering correlations between morphology and function. As seen from our injections in layer 5, for example, large neurones have large receptive fields. This is presumably due to their large dendritic fields, which enable the cells to collect input over a wide area. Another determining factor in receptive field size is the extent of axonal ramification of the inputs to a given cell. This is seen for the layer 6 cells; although their dendritic fields are relatively small, they receive input from layer 5 over a very large area, due to the wide spread of the layer 5 cell axons. The layer 5 fields may derive their large area from both mechanisms: they have very wide dendritic arbors, and the layer 2+3 cells have widely arborising axons in layer 5.

A correlation between simple receptive field type and stellate morphology was found by Kelly and Van Essen[23], but, as they indicated, this was not a strict correlation. We have injected simple cells in layer 5a and 6 that were clearly pyramidal in morphology and one complex cell in layer 6 that was stellate. Thus, the simple/complex receptive field classification seems not to be the pertinent feature in relating functional properties to the stellate/pyramidal categories. The determinant factor as to whether a pyramidal cell is simple or complex seems to be the position of its basal dendrites relative to the geniculate input. The function of apical dendrites remains unknown; they may ramify at different levels within the cortex, but so far this does not seem to correlate with any receptive field differences. It is possible that, as seen for some cells in layer 6, the role of the apical dendrite is to participate in the formation of recurrent loops within the cortex.

In addition to the dichotomy between stellate and pyramidal cells, there is, even for a given layer, considerable variability within each of these morphological classes. At this early stage in our study we do not know how this diversity is reflected in the receptive field and/or firing properties of cells. There are, on the other hand, certain receptive field features, such as orientation specificity and preference for direction of stimulus movement, which may correspond to particular aspects of dendritic arborisation. Another functional difference between cells is their inhibitory or excitatory postsynaptic effects, which depend on the transmitters they use. As mentioned above, this may be reflected in morphological differences and not in differences in receptive field properties. Pharmacological evidence suggests that inhibition is important in enhancing certain receptive field features, such as orientation specificity[51]. The relationship between function and dendritic morphology remains a challenge. We expect that further analysis of and additions to our catalogue of injected cells will reveal clues to this relationship.

We thank Drs David Ferster, Eric Frank, David Hubel, Simon LeVay and Semir Zeki for their comments on the manuscript, Lynn August, Julia Held, Karl Reich and Jane Soukup for technical assistance, Cathy Cross for photography, and Daniel T'so for help with electronics.

The 78.4-day period of Cygnus XR-1

CYGNUS XR-1/HDE226868 is a multiple star system in which the secondary is the best astronomical candidate for a black hole. The existence of a third body in the system could affect the mass derived for the secondary from the analysis of spectroscopic radial velocity curves[1]. Hence, the presence of a periodicity in the system other than that of the 5.6-d binary orbit has a major bearing on the identification of the secondary with a black hole, especially if such a periodicity can be related to the orbital period of a third body. The existence of a 78.4 (or 39.2)-d periodicity in the optical and low-energy X-ray wavelength region of the emission from this system has been reported by Kemp *et al.*[2,3]. The existence of a 39.2-d modulation in the optical and low-energy X-ray luminosities has been questioned by Walker *et al.*[4]. We report here a search for a 78.4-d modulation in the high-energy X-ray flux observed with OSO 8 and in the U-band optical polarisation previously observed[5], with negative results. We suggest, however, that if such modulation does exist, it is more likely to be related to the rotation of the free modes of oscillation of the primary than to the existence of a third body in the system.

Analysis of the power spectrum of the U-band polarisation of HDE226868 on 225 nights between 1974 and 1977 led to the original detection by Kemp *et al.*[2] of a 39.2-d modulation in the magnitude of polarisation with peak-to-peak amplitude of 0.25% (or 0.0054 mag). A modulation with a 78.4-d period was detected by Kemp *et al.*[3] in the power spectrum analysis of the U-band photometry of the system taken during 43 nights in 1974 and 84 nights in 1977. The peak-to-peak modulation was approximately 0.015 mag. A reanalysis of the UV filter polarimetry at the 78.4-d period produced a double-peaked modulation; the 0.0054 mag modulation in the polarisation was equivalent to a peak-to-peak amplitude of approximately 8% of the mean polarisation. In a similar analysis of the power spectrum of the X-ray flux in the energy range 3–6 keV from Cyg XR-1 observed between October 1974 and December 1977 with the all-sky monitor on Ariel 5, Kemp *et al.*[3] detected a 78.4-d modulation with peak-to-peak amplitude of approximately 15% of the mean flux. The modulation seems to be in phase with the U-band photometric modulation. This periodic modulation was detected only when the X-ray source was in an intensity 'low state'.

Cyg XR-1 was observed with the high energy X-ray spectrometer[6] on OSO 8 during periods of 10–20 d in each of the years between 1975 and 1977 (ref. 7). The source exhibited a transition from the intensity low state to the intensity high state during the observation in 1975 (ref. 8). Consequently, only the data obtained in 1976 and 1977, when the source was continuously in a low state, were analysed for a 78.4-d modulation. The counting rates from the source between 23 and 153 keV, binned in intervals of one-tenth the 5.5995-d binary period, were folded modulo the 78.4-d period with epoch of zero phase as given by Kemp *et al.*[3] (Fig. 1*a*). The weighted mean counting rate over intervals of 0.1 in phase are shown in Fig. 1*b* for direct comparison with the 3 to 6 keV X-ray data of Kemp *et al.* (Fig. 1*c*). The modulation observed by Kemp *et al.* at lower energies is not immediately apparent in our data. The variations evident in Fig. 1*b* have a peak-to-peak range of 19% of the mean flux between 23 and 153 keV. If any 78.4 (or 39.2)-d modulation exists in the high-energy X-ray flux from Cyg XR-1, it must be at an amplitude significantly lower than this. Because of the irregular spacing of the data and the fact that all observing runs were short compared with the 78.4-d period, no more stringent limits could be placed on the existence of a 78.4-d modulation by the use of power spectrum analysis.

Observations of the polarisation of HDE226868 in the U-band were obtained over 23 nights in 1973, 1974 and 1975 (ref. 5). The individual observations were intended to investigate short time-scale phenomena: each U-band polarisation measurement was completed in 10 min. The observations were folded modulo the 78.4-d period with the same epoch of zero

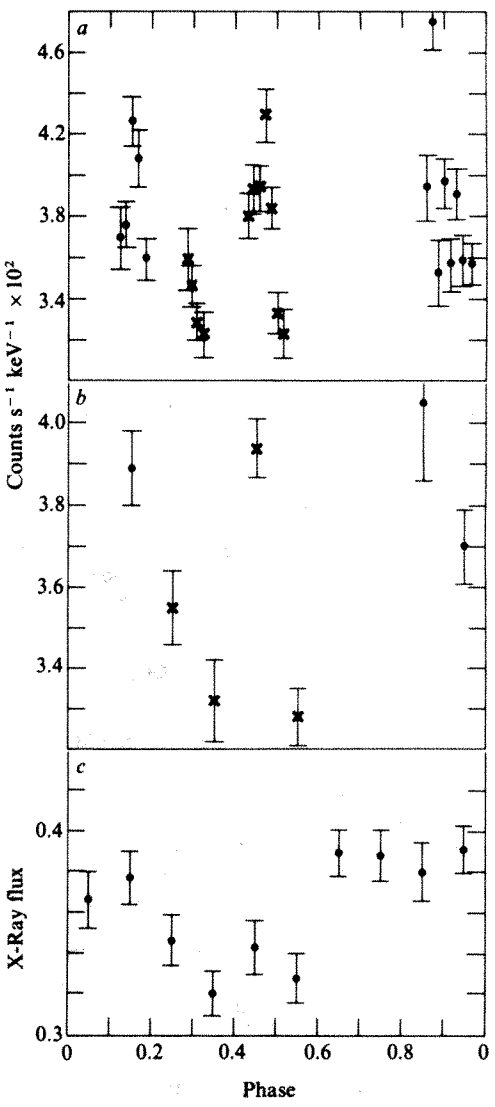

Fig. 1 X-ray counting rates observed from Cyg XR-1 plotted modulo the 78.4-d period of Kemp *et al.*[3]. (*a*), Individual observations of the 23–153 keV counting rates taken in 1976 (×) and 1977 (●). (*b*), Weighted mean counting rate of the observations in (*a*) over intervals of 0.1 in phase. (*c*), The 3–6 keV flux observed by Kemp *et al.*[3].

phase as above. The weighted mean polarisation in intervals of 0.1 in phase shows variability with a peak-to-peak amplitude of 34% of the mean polarisation. Variations typically of this magnitude have been ascribed[5] to Rayleigh scattering of light from intercomponent gas streams known to exist in the system. A χ^2 test shows that the data points are equally consistent with a random distribution about either a non-varying polarisation or the type of curve fitted to their data by Kemp *et al.*[3]. The data do place an upper limit on the existence, during our observations, of any variability of the type seen by Kemp *et al.*, but only at an amplitude four times that seen by them. Once again, the irregular spacing and greatly varying statistical weights of the individual observations preclude using a power spectrum analysis to set more stringent limits on any periodic modulation.

Kemp *et al.*[3] propose a physical interpretation of a 78.4-d period in terms of either a ternary system, the precession of an accretion disk, or some kind of pulsation. They discuss the three-body possibility, although they point out that their analysis of spectroscopic radial velocity observations of the visible primary limits any third body in the system with a 78.4-d period to a mass of less than $(0.8 \pm 0.6)\ M_\odot$. We believe that a more likely interpretation of a 78.4-d periodicity in the system, if confirmed, is related to the fundamental rotation properties of the free modes of oscillation of the primary. In the Wolff and Kondo model[9,10] of X-ray binary systems, for example, the non-degenerate star pulsates in a broad array of gravitational modes (g-modes), global in scale and lacking spherical symmetry. Under slow rotation and sufficient non-linear coupling, the g-modes can combine to form a much smaller set of non-linear modes departing from azimuthal symmetry. As the main antinodes of these non-linear modes rotate past each other, the oscillatory power density at these locations is temporarily enhanced. The occurrence of transitions between intensity states of the X-ray source is ascribed by Dolan *et al.*[7] to sudden changes in the amount of mass transferred whenever the main antinodes are aligned with the sub-secondary point on the surface of the primary. In this picture, the 78.4-d period would be the time between effective alignments of certain g-modes.

As noted by Kemp *et al.*[3], excess mass transfer between the binary components modulated with a 78.4 d period could explain all the modulation they see in the X-ray and UV emission. The continued existence of this period over 3 years implies that it may be maintained by some forcing function. If the 78.4-d period is an exact integral multiple of the 5.6-d orbital period of the secondary[2,3], tidal forces occurring every periastron passage of the secondary in its eccentric orbit ($e = 0.06$) could provide such a forcing function (see ref. 11). Further observations are necessary to determine whether the 78.4-d modulation can be confirmed, and whether it can be related to the rotation properties of the primary's free modes of oscillation.

Simultaneous effects of CO_2 and chlorofluoromethanes on stratospheric ozone

THE amount of ozone in the stratosphere is determined by a dynamic balance between processes from three disciplines: photochemical kinetics, radiative transfer and dynamical meteorology. These processes are interactively coupled, principally through the temperature of the air molecules; because of the low pressure and solar UV light a chain reaction is possible by which the composition of the stratosphere, and particularly its ozone content, may be affected by comparatively small quantities of trace species. Calculations have indicated that oxides of nitrogen from high-flying aircraft and nuclear weapons, nitrous oxide from artificial fertilisers and various chlorine-containing derivatives of methane and ethane (mainly CF_2Cl_2, $CFCl_3$, CCl_4 and CH_3CCl_3) could be large enough to act in this way. Reductions in ozone column density could lead to increases in the amount of solar UV light transmitted to the planetary surface in the wavelength region 290–320 nm, with possible effects on human health and biological activity. We have already shown that projected increases in carbon dioxide amounts in the atmosphere would lead to cooling and thus to ozone enhancement in the stratosphere, particularly at the upper levels. Here we extend these calculations to include simultaneous perturbations of CO_2 and chlorofluoromethanes.

The photochemical-radiative column model is as used previously[1,2], but it incorporates the following modifications. The solar radiative transfer scheme for the computation of photodissociation coefficients has been reformulated to include the effects of multiple scattering, in a manner similar to that of Isaksen *et al.*[3]. The chemical kinetic scheme has been expanded

to that detailed in Tables 1 and 2. The lower boundary conditions are as before except for nitrous oxide, the mixing ratio of which is 3.25×10^{-7}, in line with recent measurements[4]. The mixing ratios of stable chlorine-containing species are listed in Table 3; the new soluble species such as HCl have been added to the list of molecules rained out. A series of five integrations has been made, as shown in Table 3. The design of our radiative transfer scheme does not allow realistic calculation of the effects of CO_2 increases much beyond a factor or two from 350 p.p.m.v. Therefore we have not attempted to simulate the case of simultaneous projected CO_2 (approximately 1,100 p.p.m.v.) and steady state CFM amounts at 1975 release rates, which may occur about the period 2060–2070. Instead, we have computed the effects of steady state CFM release with 600 p.p.m.v. of CO_2. Integration 5 may be viewed as a possibly realistic schedule for simultaneous CO_2 and CFM release, with the former at 600 p.p.m.v. and the latter at half their steady state values. This is projected to represent approximately the period 2020–2030. It is apparent that the net decrease in ozone column density computed for this time is 2.6%. Earlier integrations performed without chlorine chemistry in the model[2] yielded an increase of 5.5% when the CO_2 was allowed to rise from 275 p.p.m.v. to 600 p.p.m.v.; the extra 2.3% compared with integration 2 of Table 3 must thus be attributed to this absence of chlorine from

Table 3 Mixing ratios of stable chlorine-containing species

Integration no.	CO_2 (p.p.m.v.)	CH_3Cl (10^{10} v.m.r.)	CCl_4 (10^{10} v.m.r.)	$CFCl_3$ (10^9 v.m.r.)	CF_2Cl_2 (10^9 v.m.r.)	% Change in ozone column density	Comments
1	275	7.5	1.25*	0	0	—	Reference atmosphere

* There may be both natural and man-made contributions to this species in the atmosphere[5–7].

the model. The remaining integrations demonstrate that the effects of CO_2 and CFMs on ozone column density are not quite linearly additive. Given this, it is apparent that in the simulated period about 2020, the CO_2 at 600 p.p.m.v. substantially alleviates the reductions in stratospheric ozone caused by continued CFM release at 1975 rates. The result of integration 4 yields a mean annual reduction of 8.6% in the ozone column density from steady state CFMs, if no increase in CO_2 over that in the reference atmosphere occurs. This is substantially less than recent estimates of some other column models[8,9], which have given figures of 15–20%. Presumably a fully diurnal model with interactive radiative transfer is more stable towards chlorine perturbation.

The comparatively small reduction in O_3 column density predicted in integration 5 was achieved at the cost of a substantial redistribution as a function of altitude, with a concomitant change in vertical temperature structure, as shown in Fig. 1. The importance of the coupling between ozone, temperature and large scale stratospheric dynamics[10] in this respect should be recalled.

Geochemical and geophysical evidence on the geothermal potential of Caledonian granites in Britain

TECHNIQUES for the extraction of geothermal energy from hot dry granite are being developed with considerable success, principally at Los Alamos, New Mexico[1–3]. The method involves drilling to depths where the mean temperature exceeds about 160 °C and then using hydraulic fracturing techniques to create an artificial fracture system through which water is circulated and recovered for energy extraction by heat exchangers. At Los Alamos, the required bottom hole temperatures are reached within 3 km of the surface (>50 °C km^{-1}). Although gradients in Britain do not reach this value, a recent economic assessment (J. Garnish, personal communication, based on data in refs 2 and 4) of UK hot rock potential indicates that the Los Alamos technique may become cost effective where the required temperatures occur at <5 km depth; an average minimum thermal gradient of 30–35 °C km^{-1}. The Cornubian granite batholith of Hercynian age and, to a lesser extent the Tertiary granites of northwestern Scotland, have been considered to have potential as hot rock geothermal sources[4,5], but less emphasis has been placed on the Caledonian granites of Britain. Recent studies of heat flow in Britain[6,7], together with an increasing volume of interpreted geochemical and geophysical data, suggest that certain Caledonian granites of Lower Devonian age may have potential as hot rock sources comparable with that of the Cornubian batholith. Few direct measurements of temperature in Caledonian terrain exist although northern England is known to have high heat flow[6,7], and here we review the available data which have a bearing on the geothermal potential of these granites.

U was determined by the delayed neutron method; K and Th were determined by instrumental neutron activation.

The first important feature is radiogenic heat production in the zone of interest. This is because of the known empirical relationship between high surface heat flow and high radioactivity in the crust: $q_0 = q^* + A_0 D$ (where q^* is the probable heat flow contribution from deep sources—the background heat flow—q_0 is the surface heat flow, A_0 is the surface heat productivity and D is a function of the thickness of the radioactive layer[7,9,10] (see also ref. 8)). The near-surface thermal gradient across a crustal segment is proportional to the measured heat flow (q_0); clearly, this will depend on both radioactivity (A_0) and the value of background heat flow (q^*). For southern Britain, Oxburgh and Richardson[7] have shown, from limited data, that heat flow and heat productivity are linearly correlated. It follows that in areas where heat flow data are limited it is important to identify zones in which q^* is likely to be most augmented by crustal heat sources. For example, the Cornubian batholith is located in a high heat flow province[4–6] and is characterised by high contents of the major crustal heat-producing radioelements U, Th and K. Shallow drilling in the Carnmenellis granite to 175 km has indicated gradients between 30 and 35 °C km^{-1} (ref. 11). The downward continuation of this gradient depends on certain assumptions about the variation of heat production with depth but there are good indications that the area is interesting from a geothermal energy viewpoint, especially where granite is overlain by low conductivity sediments.

In the Caledonian province, much of the region north of the Scottish Midland Valley is apparently underlain by a thick granulite succession[12] which, from geochemical investigations at outcrop[13–17] and from regional geochemical maps[18], appears to be depleted in heat-producing elements. The cover succession of Moine and Dalradian metasedimentary assemblages contains only low to average crustal abundances of K, U and Th as do the older, pre-Silurian granites, the migmatites and vein complexes,

0028-0836/79/270129—03$01.00

© Macmillan Journals Ltd 1979

and the newer forceful granites[13,14,17,18]. Thus, the northern British Caledonides lack high heat productivity on a regional scale, but this does not exclude the possibility of geothermal hot spots of potential interest which are now tentatively identified.

Regional geochemical maps[18] indicate a high concentration of uranium and potassium over the Cairngorm granite and further studies of the distribution of uranium concentration in British granites[14] have confirmed the relatively high levels in Cairngorm and other Caledonian granites of Lower Devonian age, particularly Etive and Monadhliath from the northern province. To emphasise this point, Table 1 compares neutron activation analyses for K, U and Th in rock samples from Cairngorm, Foyers (a nearby older 'forceful' intrusion) and mean values for some Lewisian inliers. It is clear that Cairngorm has a much higher heat productivity than Foyers and values calculated from Table 1 using appropriate conversion factors[19] are 5.57 $\mu W\ m^{-3}$ and 0.96 $\mu W\ m^{-3}$ respectively.

Lower Devonian granites with high heat productivity are a feature of the entire British Caledonides, including northern England which is a recognised high heat flow province[6,7]: geophysical[22] and heat productivity[13,14,17] data for some of these granites are compared with the Cornubian batholith[20] in Table 2. Additional geochemical data for some of these granites indicate that they have features in common with the Cornubian batholith—high levels of K, Rb, U, Th, Li, Be, low K/Rb ratios, low total Sr, low initial $^{87}Sr/^{86}Sr$ ratios and chondrite normalised rare earth element (REE) patterns characterised by light RE enrichments with marked negative Eu anomalies[13,14,17,21]. Both suites of intrusions also have large negative Bouguer gravity anomalies[21-23] which indicate that they have large volumes and extend to deep crustal levels. Studies of thin sections using the Lexan plastic film technique also indicate that uranium, at least, is located in primary mineral phases such as zircon and apatite[14,24]. Thus, the high levels of radioelements in these granites at outcrop are unlikely to have resulted from mineralisation. Together with the evidence of shallow drilling in south-west England and Weardale[11,25] this suggests that the heat productivities in Table 2 may be regarded as representative of larger volumes extending to depth, although this conclusion needs testing by deep drilling and by considering the geochemical evidence for magmatic fractionation. In the absence of heat flow data to the contrary it seems that the essential characteristics of several newer Caledonian granites are comparable with the Cornubian prospect from a geothermal viewpoint.

The factors identified here so far which favour high geothermal gradients within the top few kilometres of crust are: (1) high background heat flow; (2) high heat productivity, normally associated with granites; (3) large intrusive volumes recorded by substantial negative Bouguer gravity anomalies (see also ref. 26).

Table 2 Radioelement concentrations, heat productivities and Bouguer gravity anomaly amplitudes for selected Lower Devonian granites from the British Caledonides compared with data for the Hercynian Cornubian granite

† Refs 22, 26, 28.

‡ Average from unweathered and unkaolinised samples over entire batholith[23].

From Table 2, we deduce that factors (2) and (3) may be as effective in raising thermal gradients over the Cairngorm and Weardale intrusions as over the Cornubian batholith. Unfortunately, Weardale is the only Caledonian intrusion of those listed in Table 2 to have been drilled. Although the thermal gradient within the granite is only 31 °C km^{-1} (ref. 27), higher values may be encountered in the coalfield region to the east, within sediments underlain by granite. Such an elevated gradient may be postulated from the much lower thermal conductivity of coal-bearing strata which effectively insulate the underlying region. Another factor favouring high thermal gradients in shallow crust arises: (4) a low conductivity sedimentary cover.

It follows that large volume radioactive granites buried beneath suitable sedimentary sequences provide prime targets for hot rock geothermal exploration. In the British Caledonides such granites may be identified from lows in the Bouguer gravity field since, at outcrop, only this type of granite is associated with high radioactivity.

In conclusion, there are several important geothermal targets in the British Caledonides which might usefully receive further attention (see ref. 28). These include the northern England granites, including postulated buried granites in eastern England (for example, at Market Weighton[29]) and the region surrounding the Cairngorm and related intrusions. All but the latter lie in a high heat flow province and the Lower Devonian granites of northern Scotland may prove to be relative hot spots in an otherwise barren geothermal province.

This work is published by permission of the director of the Institute of Geological Sciences. The work undertaken by M.K.L. was supported by the EEC and the Department of Energy. Instrumental neutron activation analysis was performed at AWRE, Aldermaston, under the direction of G. C. Goode and T. J. Herrington. We thank S. W. Richardson for helpful criticisms.

Pliocene eustasy and the onset of sand barrier formation in Gippsland, Victoria

GIPPSLAND possesses a classical development of coastal lakes formed behind a sand barrier system which achieved its present form during the Quaternary. New evidence is assembled here, showing that a transgressive–regressive–transgressive cycle in the late Miocene–Pliocene ended in an earlier phase of barrier formation and lacustrine deposition. Another period of regression in the late Pliocene completed the cycle. Sufficient remnants of the deposits of the Pliocene lake and sand barrier have survived Pleistocene erosion to establish their former existence.

The Gippsland Lakes (lat 38° S. long 148° E.) are a series of brackish and freshwater lakes (Fig. 1), distributed over an area of about 500 km^2 (refs 1, 2). They overlie a 'continental shelf basin' which has accumulated sediment throughout much of the Tertiary[3] and are separated from the Tasman Sea by a sand-barrier system which, in its present form, is undoubtedly Quaternary in age[4].

This Tertiary sequence contains evidence of a regression in the latter part of the Miocene, first expressed as a facies change from bryozoal to shelly limestone in the upper part of the Bairnsdale Limestone[5,6] (Fig. 2, phase A) and continuing during the deposition of the overlying glauconitic clays, to culminate in the phosphatic nodule bed (phases B–D). During the regression, the sea retreated from the western (Bairnsdale) area, depositing there only a reduced thickness of Tambo River Formation[3]. Marine sediments of younger age are known in outcrop only from the Lakes Entrance–Lake Tyers area and in deep wells south and south-west of Bairnsdale[5]. The early Pliocene transgression is expressed by the Jemmys Point Formation, which was deposited in the initially deeper eastern part of the basin as the sea level rose. Deposition at this time did not extend to the Bairnsdale area and did not resume there until the sea level had risen sufficiently. The Jemmys Point Formation is composed of marine silty clay and near its base it contains a molluscan fauna including the tropical bivalve genus *Pinctada*

(the 'pearl shell'), suggesting a warm water environment. It is dated by a lower pelagic foraminiferal zone of *Globorotalia puncticulata*, overlain by a zone of *G. inflata*. In this latter respect, it resembles Pliocene zones in New Zealand[7].

Just below (1–2 m) the top of the Jemmys Point Formation, a bed of cross-bedded sandstone (Fig. 2, Bed F) is intercalated in the otherwise predominantly argillaceous sediment. In places, it possesses sedimentary structures similar to those described from California in a beach formation resting on an unstable substratum[8]. This bed is traceable along the strike for at least 16 km; its continuity and contrasting lithology are highly significant in a depositional facies not noted for continuity of individual beds. This bed is overlain by a further development of the same argillaceous lithology that comprises the bulk of the Jemmys Point Formation, but never more than 2 m thick. However, it has a more estuarine aspect, as evidenced by the abundance of carbonaceous plant debris in the sediment.

Above this level, near the present coast, the depositional facies changes abruptly to littoral sandstones (up to 10 m in thickness), intertwining with lacustrine sediments (Fig. 3). These latter (Moitun Creek Formation) are traceable intermittently for 60 km westwards from Lake Tyers and remnants can be seen as far away as 90 km to the south-west, near Longford[9]. At some places (for example, Red Bluff and Cross's Landing), sections through the littoral sandstone facies show up to 10 m of relatively coarse sandstone and shell fragments, suggesting barrier remnants; elsewhere (such as at the east side of Lake Tyers and Bunga Creek) finer grained sandstones with occasional marine fossils suggest beach or dune developments and both types of sandstone are seen to intertwine with brown siltstones of lacustrine origin. The extent of the Jemmys Point Formation, landwards of the barrier remnants and overlain by the Moitun

0028-0836/79/270131—02$01.00
© Macmillan Journals Ltd 1979

Creek Formation, suggests that the barriers occupied an offshore position at the time of their initial formation.

Noteworthy features of this sequence are that the degrees of overlap suggest that the Miocene transgression extended further inland than the Pliocene transgression, suggesting in turn that the Miocene sea level was relatively higher than that in the Pliocene. During the late Miocene regression, non-marine sediments were not deposited on the emerged sea floor, which was not covered by sediment until the Pliocene transgression, with the unusual event of lacustrine sediments deposited behind the sand barrier being transgressive. However, during the late Pliocene regression, the Haunted Hill Gravel was deposited on the emerged sediment surface composed of Moitun Creek and Nyerimalang Formations. Rapid accumulation of Haunted Hill Gravel is suggested by its poorly sorted character and relatively rapid regression is also indicated.

Recent field work[10] at Lake Tyers has demonstrated a regressive sequence in the mid to late Miocene, from the Bairnsdale Limestone to the phosphatic nodule bed (Figs 2 and 3), a fuller account of which will be given elsewhere. This Miocene regression is widely recognisable[11]. The resumption of deposition on the Gippsland continental shelf in the early Pliocene, following the regression, is also compatible with world-wide seismic data[11] and with the transgressive stratotypes of the Pliocene Stages (Tabianian–Piacenzian) in northern Italy[12], overlain by late Pliocene limestone ('Astian' facies). In the Piacenzian, there is also a lower zone of *Globorotalia puncticulata* and an upper zone of *G. inflata*, though with two intermediate zones[12] which have not yet been recognised in Gippsland. In East Anglia (UK) there are no sediments representing the Miocene transgression, but the phosphatic 'boxstones' of Suffolk occur on an unconformity surface[13]—a stratigraphical position compatible with an interpretation of their formation during a period favourable to world-wide phosphatic deposition in the late Miocene[10]. The overlying Pliocene deposits ('Coralline Crag') have been described as submarine banks[14,15] which in a general sense are not greatly different from sand barriers, suggesting an incidence of coastal sand bar formation in the Pliocene, similar to that in Gippsland. One notes also, transgressive–regressive cycles in the Pliocene of South Australia[16], South Africa[17] and Morocco[18].

The strongly onlapping lacustrine sediments of the Moitun Creek Formation (Figs 2 and 3, Bed H) represent deposition at the time of maximum transgression in the Pliocene, after which another regression occurs. The widespread lacustrine sediments require a barrier to account for their non-marine sedimentary facies and a phase of high sea level to account for their areal extent (see Fig. 3). Non-marine clays, sands and gravels (Haunted Hill Gravel) overlie the sediments of phase H–I and these formed during the late Pliocene regression.

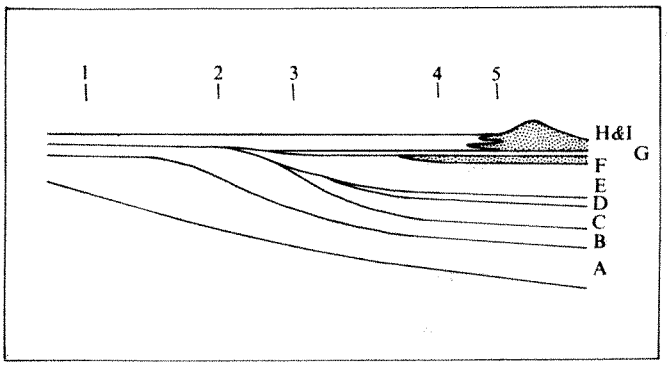

Fig. 3 Reconstruction of the northeastern part of the Gippsland Basin, showing Neogene formations at the end of the Pliocene transgression, before the late Pliocene regression and Pleistocene erosion (not to scale). 1, Bairnsdale; 2, Swan Reach; 3, Nungurner; 4, Lakes Entrance; 5, Lake Tyers. H, Moitun Creek Formation; I, Nyerimalang Formation. Other lettering as in Fig. 2. Stippling indicates sand barrier formations.

During the Pleistocene, coastal erosion destroyed most of the Pliocene barrier and undoubtedly redistributed its sediments during the periods of high sea level and probably also destroyed some of the lacustrine deposits. In the intervening periods of low sea level, river erosion removed large sections of the lake deposits.

It follows from the field evidence that the initial sand barrier formed after a period of rising sea level. Its establishment may have been due to a period of sea level stability but there is no positive evidence either for or against a postulated still stand. It is clear, however, that a further rise of sea level occurred after the initial barrier formation, causing the destruction of the first barrier, whose remnant can be seen (Bed F) but formation of a second barrier (Bed I) and a further rise of sea level allowed the formation of a coastal lake, in which Bed H was deposited.

The presence of Pliocene barrier remnants in Gippsland suggests that, in areas where extensive sand barriers still exist, it would be worthwhile seeking evidence of Pliocene precursors of these barriers, in view of the support they give to the concept of Pliocene eustasy and to the likelihood that they formed at times of still stand during a generally transgressive regime.

Holocene submergence of southern Long Island, New York

RATES of submergence of the northeastern seaboard of the US during the past several thousand years as determined from studies of coastal marsh deposits show considerable variation. The marshes became established on submerging shorelines and have grown upwards and landwards with the continued relative rise in sea level, thereby often forming thick deposits of peat. A series of radiocarbon dates taken at various levels in the marsh can be used to reconstruct the history of submergence. This letter presents a study of the relative change in sea level in southern Long Island, New York, over the past 8,000 yr, and shows that the changing rates of submergence have been an important factor in the initiation and continued development of the area's saltmarshes.

Samples of basal peat from south-central Long Island were dated by the radiocarbon method and a local curve of submergence was constructed for the past 8,000 yr. Three basal-peat samples from marsh areas behind the modern barriers have been dated in the present study. In addition, two previously unpublished dates of organic-rich silty clays (originally back-barrier deposits) from the modern shoreface became available.

Two shallow basal peats from the back-barrier area were collected by hand coring in the saltmarshes fringing the northern margins of western Great South Bay (Fig. 1). Another sample of

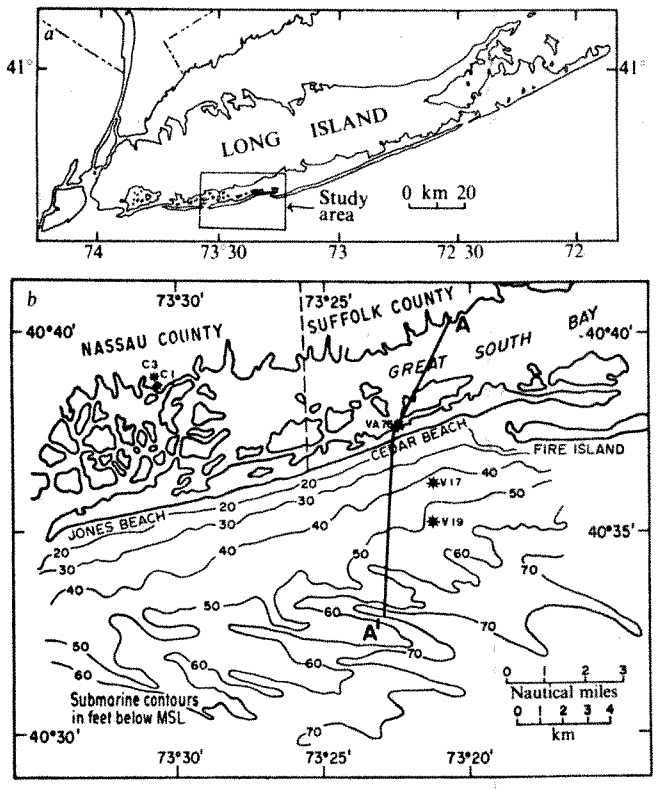

Fig. 1 Location map of the study area showing positions of the borings and cores (*) from which radiocarbon-dated material was taken. Data from the line of borings, A to A', were used to construct the section in Fig. 2. Offshore contours after Williams[4].

basal peat was collected by vibracoring at a depth of −10 m MSL directly behind and beneath the modern barrier island. Locations of these radiocarbon-dated cores are shown in Fig. 1; the dates are plotted on a schematic cross-section of the Holocene stratigraphic sequence as determined from several hundred boreholes and cores in Fig. 2.

Basal peat in tube core 1 was dated at 1,015 ± 100 yr BP (Queens College no QC-315) at approximately −1.1 m MSL. Basal peat in tube core 3 was dated at 300 ± 85 yr BP (QC-316) at approximately −0.3 m MSL. The peat sample taken from vibracore VA-76 at approximately −10.1 m MSL was dated at 5,055 ± 120 yr BP (QC-314).

For each of these dates the samples were of salt- to brackish-water peat, directly overlying Upper Wisconsinan glacial outwash. Therefore, compaction of the underlying outwash sands and gravels is thought to have been minimal.

Organic silty clays collected by vibracoring on the modern shoreface (Fig. 1) were also dated by the radiocarbon method. These former back-barrier sediments were taken from vibracore V-17 at a depth in the core of 1.0 m in 12.6 m of water and from vibracore V-19 at 0.16 m core depth, in 16.4 m of water (Fig. 2). The sediments are lagoonal or saltmarsh deposits now exposed on the shoreface by barrier retreat. These deposits mark the position of a former back-barrier lagoon which existed when the barrier islands were located some 7 km south-east of the present shoreline. The detailed history of the retreat of the barriers of southern Long Island will be discussed elsewhere[1]. These back-barrier sediments were probably deposited at or slightly below sea level. They are over-consolidated, which indicates post-depositional compaction. Radiocarbon dating of these silty clays, performed on total organic material in the samples, gave 7,815 ± 300 yr BP for sample V-17 (1.0 m) and 7,130 ± 380 yr BP for sample V-19 (0.16 m) (dating by Teledyne Isotopes).

These dates from south-central Long Island have been compared with other published dates and curves of Holocene sea level from the Long Island area[2–4], and with the submergence curves which have been constructed for adjacent areas of the Atlantic Coastal Plain[5–8] (Fig. 3).

The submergence curve constructed from the data for southern Long Island represents the combined effects of eustatic sea-level rise, local tectonism, tidal variation, water loading and other variables. Therefore, the curve cannot be extrapolated directly to other areas. However, the submergence curve for south-central Long Island can be used in palaeogeographic reconstructions to locate the position of the palaeoshoreline, and as an indicator of changes in the relative rates of submergence during the past 8,000 yr.

The submergence curve constructed from these data suggests that between 7,000 and 3,000 yr BP the Long Island coast was being submerged at a rate of about 25 cm per 100 yr, and that during the past 3,000 yr, the submergence rate slowed markedly to about 10 cm per 100 yr. Rates of submergence before 7,000 yr BP are uncertain. Sea-level data presented here show considerable scatter before 7,000 yr BP (Fig. 3). It has been suggested that, between 9,000 and 7,500 yr BP, submergence rates in adjacent coastal areas were as high as 50 cm per 100 yr (refs 9, 10).

The submergence curve for Long Island, therefore, shows a marked reduction in submergence rate at about 3,000 yr BP, and the possibility of an earlier reduction in the rate of submergence at around 7,000 yr BP. Studies of relative sea-level rise in other areas of the Atlantic coast have outlined a similar history of changes in the submergence rate[5,11–13]. For example, the submergence rate for the Delaware coast was approximately 47 cm per 100 yr between 10,000 and 7,000 yr BP, slowed to 20 to 30 cm per 100 yr from 7,000 to 4,000 yr BP, and has continued at about 8.0 to 12.5 cm per 100 yr for the past 3,000 to 4,000 yr (refs 14, 15). Note, however, that the smoothly averaged curves presented here could be reinterpreted in terms of fluctuating relative sea level.

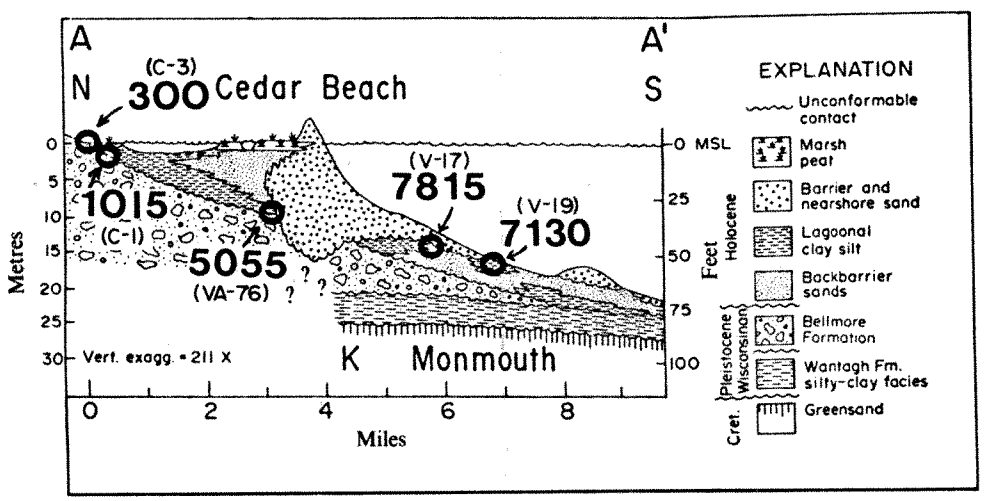

Fig. 2 Radiocarbon-dated samples plotted on schematic, interpretive profile and section A to A' showing the Holocene and Late Pleistocene stratigraphy of south-central Long Island. The positions of samples C-1 (1,015 ± 100 yr BP) and C-3 (300 ± 85 yr BP) are projected from cores to the west of this section.

The method of determining relative sea level by point-plotting the ages of basal-peat samples, and then drawing a best-fit curve will average out any fluctuations in the history of submergence. Postulated curves of fluctuating sea level[16] cannot be adequately tested in this manner. Careful stratigraphic analyses are required to test such an hypothesis.

One possible method is to study the stratigraphy of saltmarshes to determine changes in vegetational patterns and shifts in marsh environments that would accompany variations in sea level. No such consistent variations were found in examination of the cores of marsh sediment recovered in the present study.

It has been suggested that changes in the rate of submergence have been an important factor in the development and maintenance of back-barrier saltmarshes[5,11,17]. The radiocarbon dating of basal peats from southern Long Island sheds light on the mode of formation of the marsh areas. Peat samples from approximate depths of −1.1 and −0.3 m MSL gave radiocarbon ages of 1,015 ± 100 and 300 ± 85 yr BP, respectively (Fig. 2). These samples of brackish to saltmarsh peat presumably mark the approximate positions of sea level at those times. The fringing and mid-bay marsh areas of Great South Bay are therefore rather young. Peat has been probed with steel rods to depths of about −2 m MSL which, according to sea-level curves for adjacent areas, would put the inception of these marsh areas at about 2,000 yr BP (Fig. 3).

This conclusion is supported by the report of a basal peat layer at a depth of −7.5 feet (−2.4 m) MSL in Shinnecock Bay, in eastern Long Island, dated at 2,300 yr BP[18]. This date indicates that the back-barrier marshes in eastern Long Island were established at least 2,300 yr ago.

It seems that a back-barrier environment, with open-lagoonal conditions, existed for some time before the more recent development of the saltmarshes. The colonisation of previously open-lagoon environments by marsh grasses may have been related to a lessening in the submergence rate in the area about 3,000 yr BP. A decrease in the rate of submergence would have allowed sedimentation to build the floor of the lagoon to a level at which the marsh grass *Spartina alterniflora* could grow. As stands of *S. alterniflora* became established and began to trap fine sediment particles, a thin layer of peat would form across former tidal-flat areas. Once the level of the marsh had built to about mean high water, *Spartina patens* could colonise the marsh surface, and marsh building would continue to keep pace with submergence, thus forming the present marshes[5].

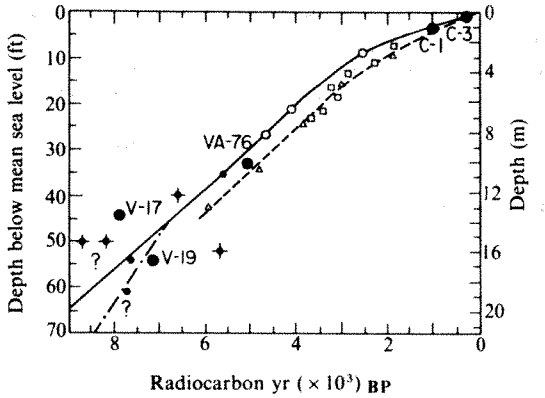

Fig. 3 Submergence curve for southern Long Island during the past 8,000 yr (solid curve). The curve is based on radiocarbon-dated samples reported in this paper (large solid circles) and on previously published dates from northern Long Island[3,4] (crossed solid circles), southern Long Island[2,4] (small solid circles) and Iona Island, New York[7] (open circles). The dashed and dotted curve indicates possible submergence rates of ~50 cm per 100 yr before 7,000 yr BP suggested for adjacent areas[9,14]. The dashed curve is drawn through points of dated samples from New Jersey[6] (triangles) and Cape Cod, Massachusetts[5] (open squares). An assumption of relatively smooth change in sea level has been made in constructing these curves.

In many studies of saltmarshes of the northeastern United States, a relationship has been established between marsh initiation and a marked slowing in the submergence rate between 3,000 to 4,000 yr BP[5,11,13,17]. It seems likely that the change from open lagoon with intertidal-flat areas to saltmarsh was initiated in western Great South Bay by a decrease in the rate of submergence at about 3,000 yr BP. This slowing of the submergence rate allowed sedimentation to build up the floor of the lagoon by about 2,000 yr BP, to a point at which marsh grasses could colonise former tidal-flat areas along the northern margins of the lagoons and also grow on former tidal-delta deposits. For the past 2,000 yr, upward marsh building has for the most part kept pace with the slow submergence.

I thank Professors J. E. Sanders and R. W. Fairbridge for helpful discussions, Joseph S. Ward and Co., and the Suffolk County (New York) Department of Environmental Control for providing radiocarbon-dated samples from offshore cores, and R. Pardi (Queens College Radiocarbon Laboratory) for performing other age determinations. This work was supported in part by grants from the Geological Society of America, and by NASA grant NSG 5163 to Columbia University.

Mössbauer spectral studies of the diagenesis of iron in a sulphide-rich sediment core

ONE stage in sedimentary pyrite formation[1–3] is 'FeS' + S → FeS_2, where 'FeS' represents black precursor sulphides such as amorphous iron sulphides and fine-grained mackinawite ($Fe_{1+x}S$). We report here a Mössbauer spectral study of the formation of pyrite, in sulphide-rich sediments, from the reaction of H_2S with hydrated ferric oxides and with ferrous ions in fine-grained chlorite or in amorphous silicates. Approximately 50% of total Fe deposited is converted to pyrite within a few years, with the remainder being converted over several hundred years. Less than 10% of total Fe is present as precursor sulphides. With suitable constraints in computation, Mössbauer methods show considerable potential for measuring rates of reaction of iron compounds in sediments.

Lake St George is a kettle lake situated 60 km north of Toronto, Ontario. It has a surface area of 10 hectares, a maximum depth of 14 m, and is strongly stratified from May until turnover in late October, with the thermocline at ~9 m. The

0028-0836/79/270134—03$01.00

© Macmillan Journals Ltd 1979

surface sediments are rich in organic matter (~25% dry weight) and in sulphide (1.7% total S in the top 6 cm, increasing to ~2.2% below 50 cm, compared with 1.6% Fe). Optical and scanning electron microscopy showed abundant pyrite framboids in all sections of core. X-ray diffraction methods revealed in decreasing order of abundance, quartz, calcite, feldspar, pyrite. Cores were obtained through surface ice in December 1977 using a photoactivated-sphincter lightweight corer[4]. The uniformly grey cores were extruded, sectioned and bottled under nitrogen, to minimise oxidation. The fractions were frozen immediately and freeze-dried 8 h later on return to the laboratory. Mössbauer spectra of the freeze-dried residuals were recorded in January 1978 at University College of Wales, Aberystwyth, and McMaster University, and computer-fitted using Stone's programs[5]. Half widths and peak areas within a quadrupole doublet were constrained to be equal. Low-spin ferrous ions in pyrite and high-spin ferric ions give rise to superimposable doublets[6,7], and additional constraints invoked are described below. The Ambrosia pollen horizon occurs at 15 cm, corresponding to colonial settlement in ~1830; this is consistent with current rates of sedimentation of ~1 mm yr^{-1} calculated from the weight of material collected in sediment traps.

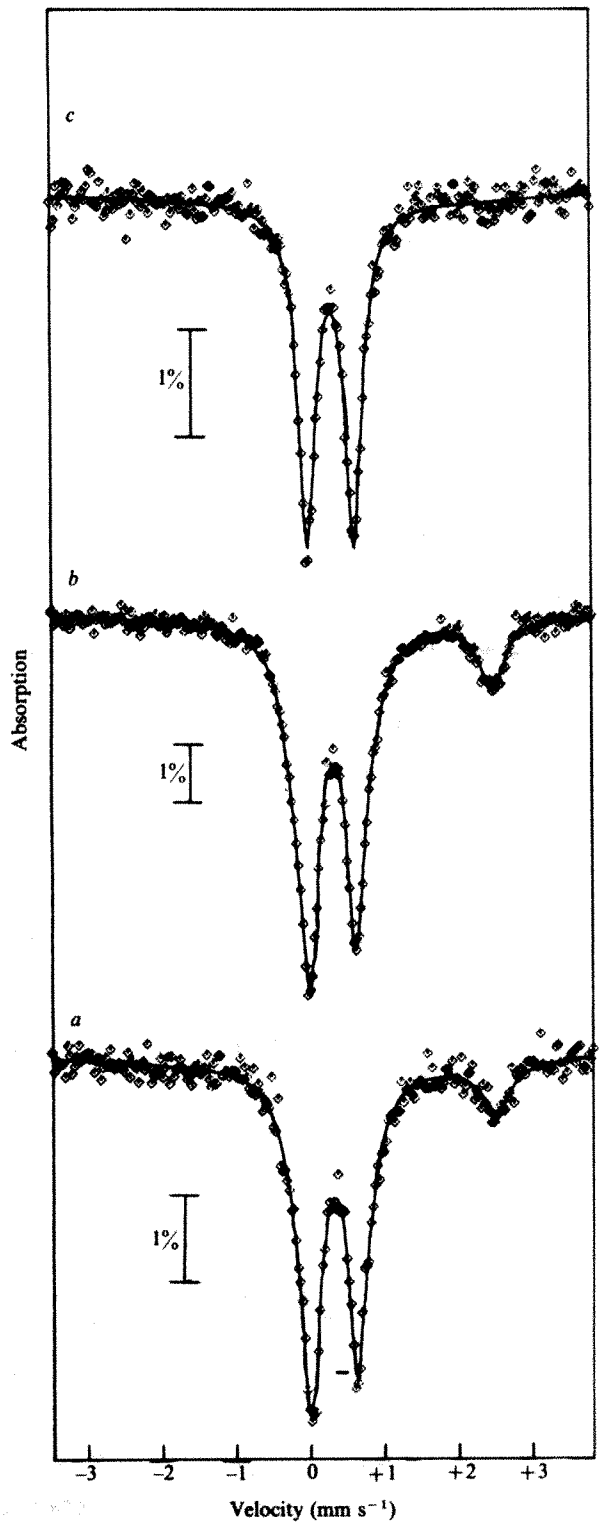

Fig. 1 Room-temperature Mössbauer spectra of freeze-dried Lake St George sediments: *a*, 0–1 cm; *b*, 1–2 cm; and *c*, 86–88 cm fractions. Continuous line represents a computed fit, based on one doublet for the 86–88 cm fraction and on three doublets for the other two. χ^2 values are, respectively, 220 with 239 d.f., 260 with 239 d.f., and 270 with 244 d.f.

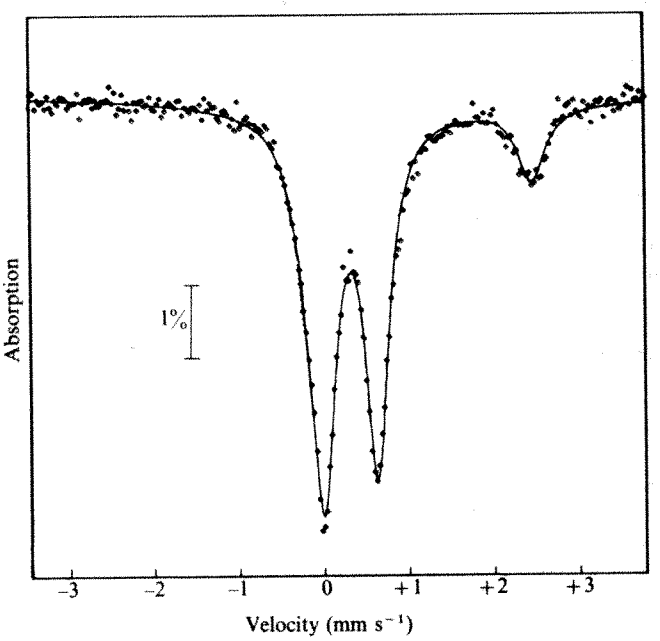

Fig. 2 Room-temperature Mössbauer spectrum of 1-2 cm fractions of Lake St George sediment, showing the two-doublet computed fit as the continuous line. χ^2 value is 339 with 240 d.f.

Selected Mössbauer spectra of sediment residuals are shown in Fig. 1. The disappearance of a 2.6 mm s^{-1} high-spin ferrous peak in spectra of the deeper fractions is clear evidence for diagenesis. Spectra of 50–52 cm, 62–64 cm and 86–88 cm fractions are virtually identical, and a one-doublet fit yielded values of isomer shift (IS) = 0.31 ± 0.01 mm s^{-1}, quadrupole splitting (QS) = 0.61 ± 0.01 mm s^{-1}, and half width (HW) = 0.285 ± 0.005 mm s^{-1}, which are clearly indicative[6] of pyrite (Table 1). Similar half widths were measured for powdered pyrite crystals from Tanybwlch Beach, Aberystwyth. Attempts to force-fit the spectra to two doublets by constraining pyrite peak positions and by constraining the peak positions and half widths for amorphous ferric compounds (using values of IS = 0.37 mm s^{-1}, QS = 0.67 mm s^{-1} and HW = 0.52 mm s^{-1} measured earlier[7] for Bay of Quinte, Ontario muds) were either unsuccessful or did not yield significantly lower values of χ^2. We estimate that >90% of total Fe is in FeS_2; based on 1.6% Fe, the S requirement is ~1.85%. However, 2.2% total S was measured.

Mössbauer spectra of 0–1 cm and 1–2 cm (Fig. 1) and 4–6 cm fractions are virtually identical. A two-doublet fit yielded hyperfine parameters for high-spin Fe^{2+} (the outer doublet) of IS = 1.15 mm s^{-1}, QS = 2.65 mm s^{-1} and HW = 0.40 mm s^{-1},

and for the inner doublet corresponding values of 0.32 mm s^{-1}, 0.62 mm s^{-1} and 0.32 mm s^{-1}, all values ±0.01 mm s^{-1}. The former set is reminiscent of octahedrally bonded Fe^{2+} in chlorite[7-9], whereas the second set is indicative of pyrite. Compromising the two-doublet scheme are the consistently poor fits on the high-energy limb of the main envelope (Fig. 2) and the significantly larger half widths of the inner doublet (0.32 mm s^{-1}) compared with the 0.285 mm s^{-1} values computed for pyrite in the deeper sections. A three-doublet fit with no additional constraints gave erratic results, so pyrite peak positions and half widths were fixed at values derived from the 50–52 cm, 62–64 cm and 86–88 cm fits. Computed hyperfine parameters and Fe distributions, showing good consistency, are listed in Table 1, together with Fe distribution for 20–22 cm and 44–46 cm fractions. The ferric parameters are in good agreement with those derived for hydrated ferric oxides in muds from other lakes[7-10].

The results suggest that pyrite forms from the reaction of H_2S with ferrous ions located in fine-grained chlorite or in an amorphous silicate and with ferric ions in mainly amorphous hydrated oxides. In contrast, chlorite-bound ferrous ions in Moira Lake, Ontario, muds (total S ~2%, total Fe ~4.5%) are not attacked[10] by H_2S. QS values measured for high-spin ferrous ions in Bay of Quinte[7] and in Lac Phillippe (P.G.M., unpublished work), Quebec, muds are 2.55 mm s^{-1} and 2.50 mm s^{-1}, respectively, suggesting significant differences in structure and/or composition of the host material; the latter value, in particular, seems outside the range for most chlorites[8]. Significant amounts of ferric ion persist for ~200 yr (~20 cm burial) in these reducing sediments, in contrast to conventional views[11]; they may represent 'aged' (polymerised?) refractory oxides. The mackinawite spectrum[12] is a single peak with a small shift of 0.2 mm s^{-1}; because of the satisfactory fits obtained with three doublets, it is considered improbable that >10% of total Fe is in mackinawite. Amorphous Fe–S compounds in the upper few cm are probably oxidised on turnover, but quantitatively similar Fe distributions were obtained in September and early-October samplings. Because such compounds probably contain high-spin ferrous ions which will absorb away from the main envelopes, we estimate that <10% of total Fe is in amorphous sulphides.

Although the upper few cm of sediment are probably well mixed on turnover, it would seem that ~50% of deposited iron is converted to pyrite within, say, 10 yr, 80% is converted over ~200 yr, and >90% over ~500 yr. The relative rates are explicable because the concentrations of organic matter and the activity of sulphate-reducing bacteria are greatest in the upper few cm. Framboids were observed in the sediment traps, indicating pyrite formation in the water column during the summer.

Table 1 Hyperfine parameters* and Fe distributions† in Lake St George sediments

A new 14 Å mineral of the birnessite group in deep-sea micronodules

EXPERIMENTS by Feitknecht and Marti[1] and more recently by Giovanoli *et al.* have shown that oxidation of $Mn(OH)_2$ in NaOH solution gives rise to a Na-buserite. Drying Na-buserite converts it to Na-birnessite. If a solution of a calcium salt is shaken with Na-buserite the latter is transformed into pseudo-hexagonal Ca-buserite, characterised by a basal spacing of 10 Å. After drying this spacing is reduced up to 7 Å and buserite is converted into Ca-birnessite. We describe here a new natural Ca-bearing member of the birnessite group of unit cell parameters comparable with those of a synthetic compound described[2] as Na–Mn (II, III) manganate, belonging to the birnessite group. In ASTM (23–1046) this substance is called Na-birnessite.

Dark brown-black nodules about 0.5 mm in diameter have been found in one of the coccolith mud specimens collected in

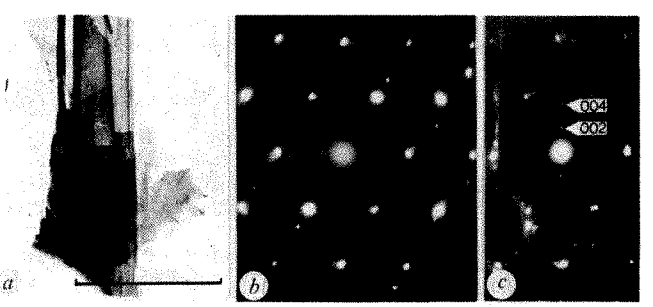

Fig. 1 *a*, Electron micrograph of 14 Å Ca-bearing birnessite. *b*, SAD-pattern of one platelet corresponding to the plane (001) of this mineral lattice. *c*, Diffraction pattern of a bent platelet edge. Arrows show the basal reflections 002, 004. Scale bar, 1 μm.

1977 from the Atlantis fracture zone (Atlantic Ocean) at a depth of 5,520 m (270–280 cm below the sediment–seawater interface), by the 24-th Expedition of RV Academician Kurchatov.

Selected area electron diffraction (SAD) and spectrometer studies of energy dispersion (Kevex) of these nodules revealed two manganese oxide minerals, one of which was named the orthorombic 14 Å Ca-bearing mineral of birnessite group. The particles of this mineral are elongated platelets (Fig. 1*a*) ranging in length from fractions of a micron to several microns. When splitting these elongated platelets into still narrower laths, the width range is greater. Many platelets display double or treble intergrowths. The SAD-patterns of single platelets normal to the beam (Fig. 1*b*) consist of a pseudohexagonal net of closely spaced point reflections. However, an analysis of the diffraction patterns has shown that the hexagonal arrangement is distorted, the extent of distortion varying from particle to particle. SAD patterns of platelets with bent edges and of platelets tilted to the electron beam have been obtained with 00*l* and *hkl* reflections respectively (Fig. 1*c*). From the diffraction pattern data averaged over a number of particles we determined the unit cell parameters as $a_0 = 8.52$ Å; $b_0 = 15.1$ Å; $c_0 = 14.1$ Å. We named this phase orthorombic 14 Å-birnessite. The established unit cell parameters are almost identical with those of synthetic Na-birnessite of the formula $Na_4Mn_{14}O_{27}.9H_2O$ having: $a_0 = 8.54$ Å; $b_0 = 15.39$ Å; $c_0 = 14.26$ Å. Slight differences in the b_0 and c_0 values can be attributed to a small variation in the degree of vacancy of the octahedral layers, and to a partial dehydration of birnessite in the vacuum conditions of the electron microscope. The mineral of birnessite group with the same unit cell parameter was synthesised in solutions of NaOH as a result of Mn^{2+} oxidation with free oxygen.

The second phase is characterised by slightly elongated laths (Fig. 2*a*) from fractions of a micron to several microns in diameter. The electron diffraction patterns of their basal planes show a hexagonal net of widely spaced *hk*0-reflections. Apart from the *hk*0 and 00*l* reflections, *hkl* space reflections have been observed (Fig. 2*b*) in many diffraction patterns of the bent edges of particles. The electron diffraction data indicate that the second phase has a hexagonal unit cell with $a_0 = 2.84$ Å and $c_0 = 7.07$ Å, both values being in accord with the parameters of common hexagonal 7 Å birnessite.

The Kevex spectrometer analysis of separate single crystal platelets has revealed that the only cations present in all the platelets of natural 14 Å birnessite are manganese and calcium. We can conclude therefore that the structural analogue of synthetic Na–Mn manganate (Na-birnessite) which we found is a 14 Å Ca-bearing birnessite.

The analysis of individual platelets of the 7 Å birnessite mineral with a Kevex spectrometer shows only manganese and calcium. Its diffraction features observed in vacuum conditions, and its chemical composition show that this birnessite is similar to rancieite. That rancieite belongs to the birnessite group (family) has been established by Bardossy and Brindley[3].

A few platelets from minerals of the birnessite group were found to contain insignificant amounts of potassium. In one micronodule the crystallites of 7 Å birnessite mineral contain minor amounts of Na in addition to Mn and Ca. Magnesium, which in principle can be detected by the Kevex spectrometer, was not found either in the 14 Å or in the 7 Å birnessite minerals of the studied micronodules.

Hence this study of micronodules from the Atlantic Ocean floor has revealed for the first time a new natural member of the birnessite group.

New fossil finds from the Libyan Upper Neogene site of Sahabi

THE site at Sahabi, Libya, was first investigated in 1934–39[1], and geological, palaeontological and palaeoanthropological research began again in 1977, as part of the International Sahabi Research Project. Further extensive fossiliferous sediments were revealed. A vertical extent of more than 80 m of such sediments are exposed, and on the basis of the mammalian fauna their age is inferred as Late Turolian to Ruscinian, 7–4 Myr BP. We present here a report of Sahabi geology and palaeontology based on results obtained up to March 1979. More than 3,000 invertebrate and vertebrate fossil specimens have been collected, and for several taxonomic groups they fill a gap in the African fossil record.

The fort at Sahabi ('Qasr as-Sahabi') is 90 km south of the coastal town of Agedabia and investigations extend to the north and east (Fig. 1). Sixty-five localities have been established (numbered P1–P65) as stratigraphic profiles or fossil sites.

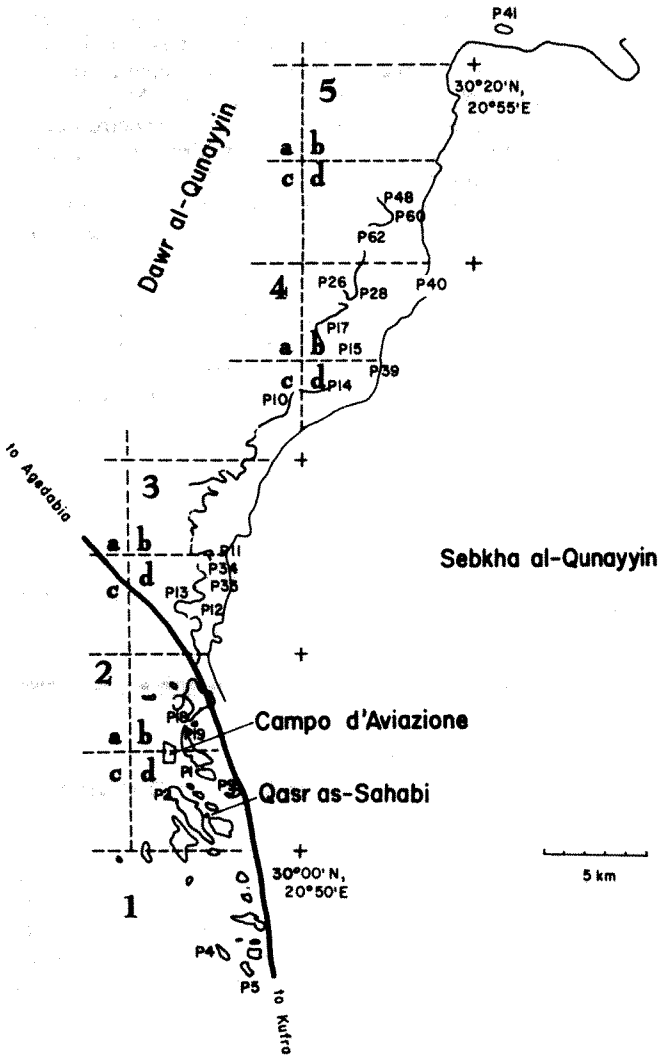

Fig. 1 Map of the major localities at Sahabi. Localities are arranged into sectors which are based on divisions of latitude and longitude. The fort ('Qasr as-Sahabi') and the 1934 Italian airfield are indicated.

De Heinzelin *et al.*[2] have defined the Sahabi Formation. It lies unconformably on a gypsiferous green clay and sand horizon known as 'Formation P', in turn overlying unconformably Middle Miocene strata ('Formation M'). P may represent deposition during the Messinian Event. Eight lithological members and sub-members (Q,R,S,T,U-1, U-2, V-1 and Z) are distinguished within the Sahabi Formation (Fig. 2). All are fossiliferous with the exception of the highest level, Z. Member Q consists of littoral and lagunal facies followed by shallow marine conditions, as indicated by the deposition of a white dolomite (Member R). Member S records the retreat of the sea by the presence of coastal facies such as lagoons, deltaic channels and freshwater basins. Shallow marine conditions return in Member T, which contains numerous mollusc shells and vertebrates (chelonians, sirenians and cetaceans). The very fossiliferous Member U comprises greenish coarse cross-bedded fluviatile sands as well as lagoonal clays.

Most fossil specimens were found on the surface, although limited excavation and sieving was undertaken. Groups thus added to the Sahabi faunal assemblage include primates, ursids, canids, sirenians, rodents, choerodonts and possibly amebelodonts. Abundant fish, reptile and invertebrate remains are being studied.

All invertebrate remains are of marine origin. Subhorizontal exposures of Formation M north of P39 (Fig. 1) preserve shallow marine, near-shore invertebrate communities, with autochthonous fossils of sea urchins, bivalves and corals. At P40 burrows referred to the ichnogenera *Ophiomorpha* and *Thallassanoides* are preserved. The gastropod *Cerithium* which lives on the bottoms of lagoons is also found in these sediments (personal communication from A. Eckdale and F. Brown). Continuing work on these fossils and on ostracods, diatoms and foraminiferans will contribute to the dating and palaeoecological reconstruction of Sahabi. Table 1 summarises the invertebrate fauna.

The vertebrate fauna is interesting for several reasons. It will provide information about the evolutionary history of several groups whose fossil records are incomplete for the period represented by these sediments. Another advantage of this fauna is that its intermediate position between Africa and Eurasia will make it possible to assess biogeographical connections between the two areas. Palaeoecological studies will be facilitated by subhorizontal exposures which preserve virtually intact fossil surfaces, frequently with *in situ* plant roots, fossil soils and footprints. Fossil wood is abundant and we are looking for pollen in samples of sediments and coprolites.

Abraded and fragmentary bones are abundant in fluviatile and deltaic facies. Rarer but more complete and semi-articulated remains occur in lagoonal and estuarine facies. Transported bone assemblages contain mixed species from different habitats: in locality P16, for example, cercopithecoids, giraffids, *Hipparion*, anthracotheres and sharks (*Carcharodon*) all occur. Table 2 summarises the vertebrate fauna from Sahabi.

The primate remains are the first from pre-Pleistocene strata in Libya. A right half-mandible (1P28A; Fig. 3*a*) and other postcranial remains are referable to a colobine, *Libypithecus* cf. *markgrafi* Stromer 1913[3]. Postcranial fossils, including a femur (1P17B) and a proximal ulna (88P36A), show close resemblances to the genus *Macaca* and are referred to cf. *Macaca*. A left clavicle (26P4A) lacking the lateral end has a large sternal articular surface, a large diameter throughout its length, a robust shaft and a strong curvature. The specimen is attributed to Hominoidea, and more precise taxonomic assessment awaits further study.

Sahabi is known for the discovery in 1934 of the type specimen of the proboscidean *Stegotetrabelodon lybicus* Petrocchi

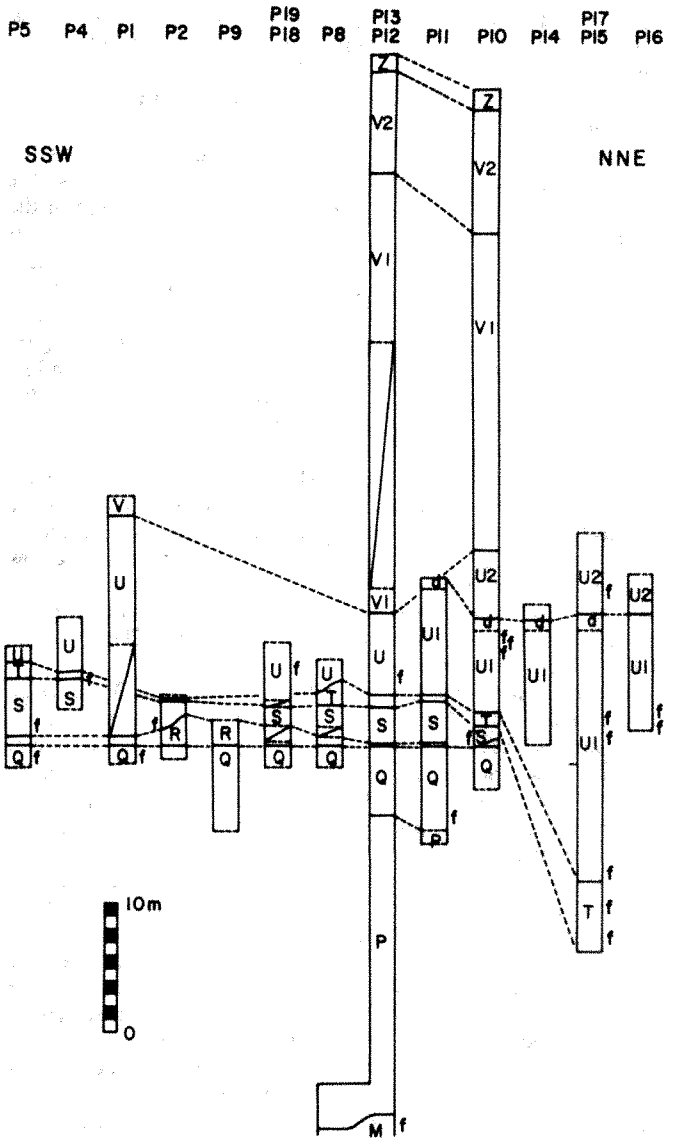

Fig. 2 Stratigraphic sections from selected localities showing 'Formation M; Formation P', and the members of the Sahabi Formation. Major fossiliferous horizons are indicated (after ref. 2). d, Dune; f, fossiliferous horizon.

1941[4]. Diverse proboscideans (Table 2) are now represented by cranial, tusk, molar and postcranial remains. *Stegotetrabelodon* is represented by a complete cranium (1P26A) and fragmentary remains. Upper tusks have almost circular cross-sections and lower tusks have oval cross-sections. The minimum length of a lower tusk is 180 cm. *Anancus* is represented by upper straight tusks with circular cross-sections, and probably also by a right lower third molar with six lophs and a bunodont structure. This specimen resembles that which Petrocchi[5] ascribed to *Pentalophodon sivalensis*.

Locality P25 yielded the remains of a proboscidean cranium, dentition and upper tusks, the latter being flat in cross-section and with 'rod-cones'[6,7]. These remains may represent *Amebelodon*. Several bunodont molars with three lophs can be referred provisionally to *Trilophodon* sp. A fragmentary proboscidean molar with only two lophs and no tubercles in the anterior valley could be from a primitive stegodont (*Stegodon*). Another proboscidean molar germ of small size with two lophs has similarities to those of choerodonts and ptychodonts. It resembles molars ascribed to *Choerolophodon* from Anatolia[7] and is assigned to *Choerolophodon* sp.

Anthracotheres represent one of the most abundant taxa in these sediments. We have provisionally assigned these specimens to *Merycopotamus petrocchii*, the name given by Black[8] to specimens found to the north of Sahabi which may or may not be of the same age as those found at Sahabi. The occurrence of hippopotamids of undiagnosed affinities together with anthracotheres is interesting as the latter have been suggested to be ancestral to hippopotamids.

Cooke[9] has discussed briefly the suids already known from Sahabi and referred them to *Nyanzachoerus syrticus* and *Nyanzachoerus jaegeri*: our discoveries are referable to the same genus. The discovery of an ursid (Fig. 3*b*) and a canid at locality P28A (U-1) relates Sahabi not only to Eurasian sites but to the South African site of Langebaanweg, dated at approximately 4 Myr, and from which *Agriotherium* and species of Canidae are known[10]. The Sahabi forms probably pre-date the South African by at least 1 Myr.

The overall complexion of the Sahabi fauna is African but several taxa indicate Eurasian affinities. These include the boselaphine *Miotragoceros*, the ursid cf. *Agriotherium*, and perhaps the proboscideans *Choerolophodon* and ?*Stegodon* and the cercopithecine cf. *Macaca*.

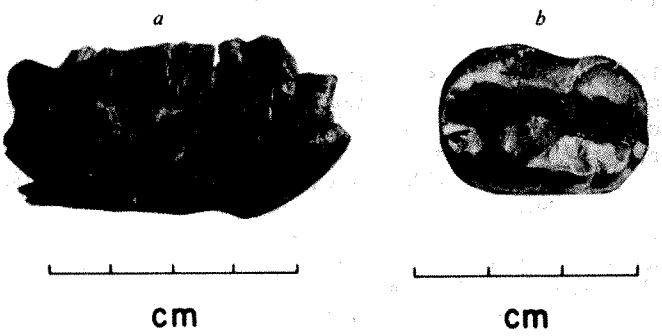

Fig. 3 *a*, Lateral view of specimen 1P28A, a right half-mandible ascribed to *Libypithecus* cf. *markgrafi*. *b*, Occlusal view of specimen 184P28A, an ursid lower molar, tentatively referred to cf. *Agriotherium*.

The nature of the terrestrial fauna indicates marshy to riverine-fringe, wooded environments proximal to the sites of deposition, and more open savanna habitats farther away. Abundant fossils of tree trunks and initial sedimentological findings confirm this reconstruction. Compared with other sites of Turolian to Ruscinian age in Eurasia and Africa, Sahabi presents a high proportion of forest, woodland or water-living forms, including abundant anthracotheres, dugongids, proboscideans, hippopotamids and crocodilids. Taxa more characteristic of open savanna conditions, such as bovids, giraffids, rhinocerotids and equids are less numerous than at contemporary sites[11]. Cercopithecids and hominoids probably belong to the water-tied or woodland group[12,13], which agrees with their absence or rarity at sites with more open habitats lacking surface water, such as Maragheh[11].

The Research Center and the Faculty of Science of Gharyounis University provided assistance in fieldwork and laboratory analysis in Benghazi and the American Museum of Natural History provided comparative specimens. We thank the government authorities in Agedabia, Mr Mustafa Ragai, Mr Ali Akush and the members of the International Sahabi Research Project for help. Research was sponsored by the L.S.B. Leakey Foundation, the National Geographic Society and Gharyounis University.

Insecticide-resistant *Myzus persicae* as an example of evolution by gene duplication

DUPLICATION of structural genes is believed to be a prerequisite for evolution because it allows forbidden mutations of the redundant copy while preserving the advantageous parental gene[1,2]. Evidence for this phenomenon is derived from studies of proteins with closely related structures which fulfil either slightly or very different roles in metabolism. The first stage of the process, duplication without subsequent mutation, leads to the production of more of a particular gene product. This is especially advantageous during development, when large amounts of ribosomal and transfer RNA are required[3]. However, so far the only examples of this mechanism causing increased production of specific proteins in response to changing environmental conditions are from studies of bacteria[4], yeast[5] and eukaryotic cell cultures[6]. Using insecticide-resistant *Myzus persicae*, we provide evidence here for gene duplication without subsequent mutation, conferring a definite selective advantage to intact higher organisms in adverse environmental conditions.

Needham and R.M.S.[7] showed a positive correlation between resistance to insecticides of the peach-potato aphid, *M. persicae*, and total carboxylesterase activity measured by the *in vitro* hydrolysis of 1-naphthylacetate. Further work demonstrated that increased esterase activity arises mainly from changes in a single enzyme, E4 (ref. 8). The increased activity is caused by the presence of more E4 rather than a more active mutant enzyme, as shown by measuring the catalytic centre activity of the enzyme from different variants[8]. As E4 hydrolyses insecticidal esters in addition to artificial substrates such as 1-naphthylacetate, it enables resistant aphids having larger amounts of the enzyme to survive otherwise lethal doses by degrading more insecticide[9].

Genetic studies of increased enzyme production gave ambiguous results[10,11], and were hampered by difficulties in breeding the aphids through their sexual cycle. Biochemical studies have now clarified the nature of this phenomenon.

Seven variants of *M. persicae* can be distinguished by esterase assays of either crude aphid homogenates or E4 after electrophoretic separation from other carboxylesterases. Although total esterase assays show a progressive increase in enzyme activity with increasing resistance, quantitative relationships are affected by the hydrolysis of 1-naphthylacetate by esterases other than E4; enzyme staining after electrophoresis only gives an approximate measure of E4 activity. However, the amount of E4 in crude homogenates is readily determined by radioassay with the insecticide paraoxon[8] (diethyl *p*-nitrophenyl phosphate prepared by oxidation of [*ethyl*-^{14}C]parathion (Radiochemical Centre)) as substrate, because only E4 hydrolyses paraoxon[8].

Weighed groups of adult apterous aphids were homogenised in 0.02 M phosphate buffer, *p*H 7.0, and incubated at 25 °C with 1.25 μM [*ethyl*-^{14}C]paraoxon, a concentration giving V_{max} for the enzyme. The hydrolysis product, diethyl phosphate, was measured at intervals by liquid scintillation spectrometry of 1-ml samples of the aqueous phase after extracting the unchanged paraoxon into 3 × 1 ml of chloroform. E4 activity (pmol per h per mg aphid) was calculated from these data and the known specific activity (40 mCi mmol^{-1}) of the paraoxon. The results showed that the rate of hydrolysis increased by the same factor between each of the seven variants. Because the catalytic centre activity of E4 for paraoxon is the same in the different variants (0.6 h^{-1})[8], the rates give a direct measure of its amount in each variant (Table 1). Statistical analysis[12] using a maximum likelihood computer program confirmed that the amounts in the seven clones form a geometric series with a factor of 1.91 and fiducial limits 1.77 and 2.12. This doubling of E4 throughout the series is best explained by a succession of tandem duplications of the structural gene for E4, with susceptible aphids having one copy, 240N two copies, and so on to G6 with 64 copies of the gene.

Excess production of E4 by *M. persicae*, in common with bacteria[4], yeast[5] and eukaryotic cell cultures[6] showing gene duplication, is unstable in the absence of selection. The two most resistant variants (PirR and G6) spontaneously revert to low esterase activity with concomitant loss of resistance when insecticide selection is removed. This is not observed with the moderately resistant variants (up to and including TIV) in which E4 production is stable.

The three most resistant variants (TIV, PirR and G6) have an A1,3 translocation[13], unlike the susceptible and the three least resistant variants (with up to eight times as much E4) where karyotype is normal. It has been suggested that this translocation, that is, an exchange between non-homologous chromosomes, or the related dissociation, is responsible for the increased production of E4 by altering interactions between genes on these two chromosomes[14]. This is reasonable in view of the location on different chromosomes of some structural genes and their corresponding regulatory genes in *Drosophila*[15,16]. The clear evidence for gene duplication as the mechanism for increased enzyme production suggests that in this case translocation is more likely to be a mechanism giving rise to tandem duplications. Other mechanisms such as exchanges between homologous chromosomes (unequal crossing over) cannot be excluded, as the karyotype of the less resistant variants is normal. Thus, resistance and the translocation do not show complete linkage as previously suggested[14].

The increased production of E4 clearly confers a selective advantage on *M. persicae* in the presence of insecticides. In Britain, the susceptible variant is now rare, almost certainly as a result of the extensive use of insecticides. It has been almost completely replaced in the field by the MSIG (R_1) variant, with four times as much E4 (ref. 9), and in some areas the even more resistant TIV (R_2) variant is common. So far, the two most resistant variants (with 32 and 64-fold increase in E4) have been widespread only in glasshouses where insecticidal application is much more intensive. These aphids are well adapted to their

environment; they have the ability both to replicate the E4 gene enabling them to survive treatment with insecticides, and to avoid excessive E4 production in the absence of insecticides because the mutational change is unstable[17]. This nullifies any possibly adverse effect on fitness through the production of very large amounts of an apparently redundant enzyme.

Nerve growth factor alters the fate of embryonic neuroblasts

RECENT work from this laboratory has documented the initial expression of the noradrenergic phenotype in autonomic neuroblasts of the rat embryo *in vivo*. Tyrosine hydroxylase (T-OH) (rate-limiting enzyme in catecholamine biosynthesis)[1], dopamine-β-hydroxylase (DBH) (which converts dopamine to noradrenaline) and the catecholamine (CA) transmitters appear simultaneously in sympathetic ganglion primordia at 11.5 days of gestation[2,3]. In addition, these noradrenergic characters transiently appear in a population of presumptive neuroblasts within the primitive gut mesenchyme[2,3]. The noradrenergic gut neuroblasts appear at 11.5 days and increase in numbers over the ensuing 24 hours. Subsequently, however, numbers decrease progressively so that by 14.5 days of gestation virtually no cells exhibiting noradrenergic traits are detectable[2,3]. Elucidation of the fate of these neuroblasts may help define mechanisms influencing neuronal phenotypic expression and/or the factors which govern selective neuronal death during ontogeny. In this report we show that treatment with the trophic protein macromolecule, nerve growth factor (NGF), increases the number of catecholamine (CA)-fluorescent cells and delays the ontogenetic disappearance of CA from the gut.

NGF is present in various sympathetic target organs, and is necessary for normal survival and growth of sympathetic neurones *in vivo* and *in vitro* (see refs 4 and 5 for reviews). Conversely, treatment of neonates with antiserum to NGF results in widespread destruction of sympathetic neurones throughout the animal[6,7]. As NGF has a critical regulatory role in sympathetic ontogeny, it was logical to define the effect of this agent on the noradrenergic neuroblasts of the embryonic rat gut *in vivo*.

At 11.5 days of gestation embryos were injected with NGF and the gut was examined for CA-containing neuroblasts. The β subunit of NGF was purified as before[8]. Pregnant Sprague-Dawley rats were anaesthetised[9], and trans-uterine injections of embryos were performed by opening the mother's peritoneum and exposing and trans-illuminating the uterus. The visualised embryos were injected using a 33-gauge needle with either β-NGF or control buffer. Animals were killed at daily intervals thereafter, from 12.5 to 15.5 days, and CA was detected by formaldehyde-induced fluorescence[10].

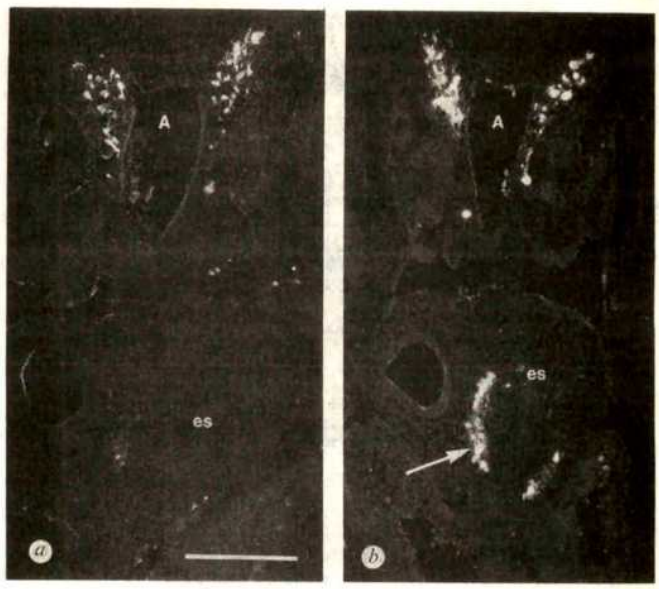

Fig. 1 Early effects of NGF treatment on CA-containing neuroblasts of the gut. Embryos were injected with either vehicle (*a*) or 50 BU of β-NGF in 5 μl (*b*) at 11.5 d of gestation; 2 d later the embryos were processed for the histochemical demonstration of CA. a, Mid-thoracic transverse section of control (vehicle-treated) embryo. CA-histofluorescence is evident in sympathetic primordia located on either side of the aorta (A). Note a small number of faintly fluorescent cells in the gut mesenchyme, adjacent to the oesophageal epithelium (es). *b*, NGF-treated embryo. Transverse section at same anatomical level as in *a*. The number and fluorescence intensity of CA-containing cells in the gut mesenchyme have increased dramatically (arrow). The neuroblasts are aggregated in ganglion-like clusters surrounding the oesophageal epithelium (es). The ganglion primordia adjacent to the aorta (A) are not significantly altered. Scale bar, 200 μm.

Treatment with NGF was associated with a dramatic increase in the number and fluorescence intensity of noradrenergic neuroblasts in the gut. These effects were most striking 2 days after injection, at 13.5 days of gestation (Fig. 1). In the oesophagus, at the level of the gastro-oesophageal junction, neuroblast numbers were markedly increased by NGF, and cells aggregated to form ganglion-like clusters (Fig. 1*b*). In contrast, far fewer CA-containing cells were detected in vehicle-treated controls, and fluorescence intensity was diminished (Fig. 1*a*). NGF induced similar increases in fluorescent neuroblast numbers and in cellular aggregation in the proximal small intestine. Although effects decreased progressively with time after injection, changes were still evident in 15.5-day embryos, the oldest specimens examined. NGF treatment caused persistence of scattered fluorescent neuroblasts in the gut of 15.5-day embryos, whereas control guts were devoid of fluorescent cells (Fig. 2). Preliminary observations suggest that the gut neuroblasts are sensitive to NGF only during a restricted period of ontogeny; treatment at 10.5 or 13.5 days of gestation had little effect.

In addition to increasing fluorescent cell numbers in the gut, NGF treatment increased the number of apparently ectopic neuroblasts in unusual locations. Fluorescent neuroblasts were observed in the liver parenchyma, the heart primordium, the somatopleural mesenchyme of the body wall and in some instances, in the limb bud mesenchyme (Fig. 3) after NGF administration.

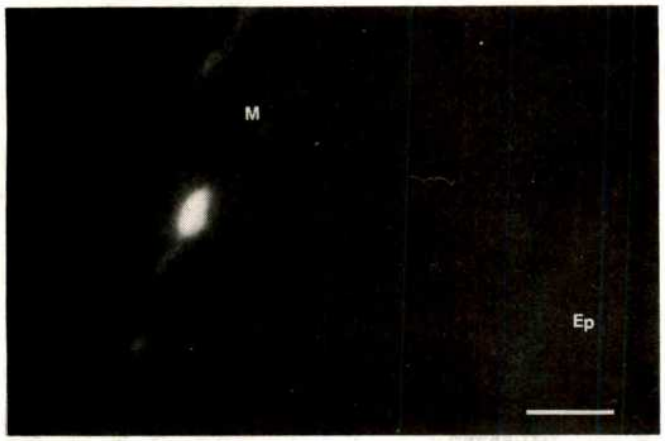

Fig. 2 Late effects of NGF treatment. Embryos were injected with vehicle or β-NGF at 11.5 d of gestation as in Fig. 1, but were examined 4 d later, at 15.5 d of gestation. An isolated fluorescent cell with a fluorescent cytoplasmic process was observed in the developing circular muscle layer of the intestine (M). Such isolated, CA-containing cells were present throughout the intestines of NGF-treated embryos, whereas the guts of controls were completely devoid of fluorescent cells. Ep denotes epithelium of the gut. Scale bar, 20 μm.

In contrast to effects elsewhere, NGF had little apparent effect on neuroblasts in the sympathetic ganglion primordia (Fig. 1). Treatment did not alter neuroblast numbers and had inconsistent, minimal effects on fluorescence intensity in the primitive ganglia. However, embryonic ganglia are responsive to NGF[11]. Consequently, our observations suggest that the exogenous dose of NGF may have been too small, compared with local endogenous concentrations, to elicit changes.

NGF may have increased the number of noradrenergic gut neuroblasts by (1) increasing the number of undifferentiated precursors that acquire noradrenergic traits; (2) causing persistence of noradrenergic traits in neuroblasts normally destined to acquire and then lose these characters; (3) causing mitosis of noradrenergic neuroblasts; (4) lengthening survival times of noradrenergic neuroblasts; (5) increasing the CA content of noradrenergic cells to the level necessary for visualisation. Alternatives (1) and (2) imply that NGF regulates phenotypic expression directly, whereas (3)–(5) suggest that NGF regulates cell number, and/or CA content, but not phenotypic expression

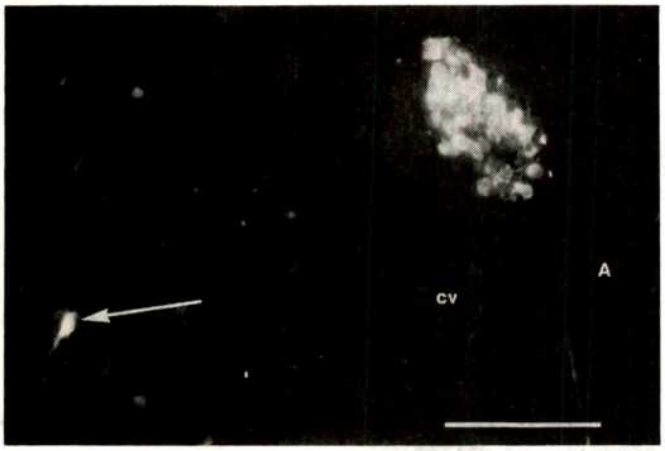

Fig. 3 Appearance of ectopic cells after NGF treatment. High thoracic transverse section of a 13.5-d embryo. An isolated fluorescent cell (arrow) is observed in the mesenchyme of the proximal portion of the limb bud. The sympathetic ganglion primordium, located between the aorta (A) and the cardinal vein (cv), is a great distance from the ectopic cell. NGF treatment increased the number of ectopic CA-containing cells in a variety of unusual locations. In contrast, ectopic fluorescent neuroblasts were very rarely encountered in controls. Scale bar, 100 μm.

per se. It is certainly well documented that NGF enhances sympathetic neurone survival during development[12,13]. However, the protein does not apparently alter transmitter phenotypic expression. Rather, NGF increases acetylcholine synthesis in cholinergic neurones, and noradrenaline synthesis in noradrenergic neurones[14–17]. It remains to be determined whether NGF influences gut neuroblasts in the rat embryo in an analogous manner. Regardless of the mechanism involved, our observations suggest that NGF can increase the number of noradrenergic neuroblasts which can be visualised in the gut and ectopic locations, and cause persistence of such cells. It is possible, consequently, that local concentrations of endogenous NGF normally determine which neuroblasts will survive and/or continue to express noradrenergic characters.

Appearance of H–W (H–Y) antigen in the gonads of oestradiol sex-reversed male chicken embryos

THERE is evidence that H–Y antigen has a major role in testis differentiation in mammals[1–3]. Presumably, this antigen is the essential factor for the development of the undifferentiated gonadal anlage into a testis. Antiserum to H–Y antigen, raised in highly inbred strains of mice and rats, exhibits cross-reactivity with cells derived from non-mammalian vertebrates like birds, amphibians and fish[4,5]. In these animals, the cross-reaction is strong in the heterogametic sex. This means that in birds with the ZZ/ZW mechanism of sex determination the female types as positive, as also occurs in the toad *Xenopus laevis*; on the other hand, in the frog genus *Rana* and the cyprinodont fish *Lebistes* and *Xiphophorus*, which have the XX/XY mechanism of sex determination, the male types as positive. This correlation with the heterogametic sex favours the assumption that the cross-reacting antigen 'H–Y' or 'H–W' in non-mammalian vertebrates

has a similar function to that occurring in mammals for the differentiation of the heterogametic gonad, that is, the ovary in ZW, and the testis in XY animals. In contrast to placental mammals, in the other vertebrates it is possible to influence gonadal differentiation by sex steroid hormones (for review, see ref. 6). In the embryonic male (ZZ) bird, application of oestrogens leads to the development of an ovotestis, in amphibians and fish, treatment with steroid hormone of the opposite sex causes complete sex reversal. If H–Y (H–W) is the differentiation antigen for the heterogametic gonad, and if on the other hand sex reversal can be achieved by the steroid hormone of the opposite sex, the question arises whether the hormone acts by way of the H–Y (H–W) antigen. Therefore, we have converted embryonic male chickens using oestrogen to develop an ovotestis, and then tested them for the presence of cross-reactivity with rat anti-H–Y antiserum. We report here that, indeed, the normally antigen-negative testis becomes antigen-positive after hormonal treatment. Thus, the gene for this antigen must be present in the genome of both sexes.

Embryos of white Leghorn chickens were used for the experiments. Eggs were injected with 100 μg oestradiol benzoate on day 4 of incubation as described, for example, by Akram and Weniger[7], and killed on days 13 or 16. Male (ZZ) converted gonads were definitely distinguished from female ones by morphological criteria. The feminised testis has the flattened form of the left ovary, but it is much smaller and its inner and outer borders have indentations, in contrast to the smooth aspect of the left ovary. The feminised right testis is longer and thinner than the right female gonad. The müllerian ducts of the feminised embryo resemble those of the female embryo, except that the left one lacks a shell gland. All these criteria taken together make the diagnosis of the genetic sex quite definite. In only three out of more than 100 cases was a decision difficult; these three embryos were discarded. Thus, gonads regarded as feminised testes were without doubt of ZZ constitution. In an additional experiment, eggs of the Ross Brown breed, which shows sex-linked differences in feather colouration, were used. Thus, this breed offers an independent criterion for sexual assignment. The plumage is brownish in females and white in males. These characters are already clearly distinct in 12-d-old embryos, and allow the genetic sex of the oestrogen-treated embryos to be determined. Sex ratios obtained according to the above criteria were:

16 d, I (Leghorn):	19♂ 24♀
16 d, II (Leghorn):	6♂ 7♀
13 d, I (Leghorn):	12♂ 15♀
13 d, II (Leghorn):	16♂ 12♀
14 d (Ross Brown):	30♂ 26 ♀

Gonads were collected in liquid nitrogen immediately after preparation and weighing, and stored at −80 °C. Untreated left testes and ovaries of embryos of the same ages served as controls. Only left gonads were used throughout the experiments, as in the female the right gonad is rudimentary. H–Y antiserum was raised in female isogeneic Lewis rats by several injections of male spleen cells as described earlier[8]. Cytotoxic testing for the detection of H–W antigen was carried out essentially according to Scheid *et al.*[9]: 20 μl 1/4 diluted antiserum was absorbed with 25 mg wet weight of pooled gonads derived from the respective type of embryo and tested for cytotoxicity on male rat epidermal cells. For each test 10 μl absorbed antiserum were used, the remainder being stored at −80 °C and tested for confirmation later on. Five experiments were carried out, two experiments each for yielding 13- and 16-d-old embryonic gonads, respectively, and another one for 14-d-old gonads of the Ross Brown breed. For each experiment about 80 eggs were used, about 50 of which were treated with oestrogens.

Figure 1*a*, *b* and *c* demonstrates the results of conversion experiments finished on days 13, 14 and 16, respectively. Converted gonads of 13- and 14-d-old embryos absorb almost as much antiserum as do normal female gonads, whereas those of 16-d-old embryos absorb a little less than do control ovaries. No elevated titres of H–W antigen were found in oestrogen-treated ovaries.

These findings clearly indicate that, after treatment with oestrogens, H–Y (H–W) antigen becomes expressed in the male gonad. This suggests that, analogous to the well studied situation in mammals, in birds the presence of H–W antigen is responsible for the formation of an ovary; if this is true, oestrogen-induced sex reversal, which is well known (for review, see ref. 6), is only an indirect effect, mediated by H–W antigen. In mammals, attempts to induce H–Y antigen by testosterone have been reviewed by Erickson[10]. Evidently, however, the primary differentiation of the gonadal anlage is independent of sex steroids in mammals (for review, see ref. 6).

It may be significant that hormone-induced sex reversal is not complete in the chick. In general, an ovotestis develops which gradually regresses towards hatching. Although, we were not able to study H–W antigen during the entire course of embryonic development, in the gonads of 13- and 14-d-old embryos, the antigen titre was clearly stronger than in those at 16 d. Therefore, there does seem to be a correlation between morphogenetic changes and the H–W titre in the gonad. Apparently, the 'induction' of H–W antigen production by oestrogen does not function by means of a switch-on mechanism resulting in the continuous production of the antigen (there must be some interaction with a repressing or degrading factor).

The results obtained in this study also have implications for the sex specificity of the H–W structural gene. Induction of H–W expression in the male bird presupposes the existence of the respective gene in the 2A, ZZ genome. Therefore, W-linkage of the H–W structural gene is excluded; this gene must be shared by both sexes. In mammals, however, the H–Y structural gene is assumed by many authors to be Y-linked[11] and consequently absent in the female. This question, however, cannot be considered as settled[12]. In addition, because in lower vertebrates sex reversal can be achieved by appropriate treatment, the gene responsible for the primary differentiation of the heterogametic gonad must be present in both sexes. From an evolutionary point of view, we believe therefore that in mammals also, this gene is not sex specific, and only its state of activity determines whether the undifferentiated gonadal anlage becomes a testis or an ovary.

Preimplantation lethality of monosomy for mouse chromosome 19

IT remains a mystery why autosomal trisomy is found more frequently than autosomal monosomy in man. Several surveys of spontaneous abortions have revealed these chromosomal abnormalities in proportions of 26% (ref. 1) and 0.1% (refs 1, 2), respectively, while a prospective study of 47,000 newborn babies revealed no full monosomy and only five cases in which parts of chromosomes were missing[3]. Similarly, in mouse embryos from translocation stocks bred to produce aneuploid progeny, high frequencies of trisomy but no monosomy are found after 12–13 days[4,5]. This is hard to understand because most autosomal aneuploidy is assumed to result from meiotic nondisjunction, so that for every gamete carrying two copies of a particular chromosome there should be a complementary gamete carrying none. However, the deficiency of monosomic embryos could be because nullisomic gametes are less able than disomic gametes to participate in fertilisation, or because the resulting monosomic embryos are less viable early in gestation. We report here the investigation of these possibilities in a mouse system which is known to produce a high frequency of nondisjunction. Equal numbers of monosomic and trisomic progeny were found early in gestation, but while some monosomies were compatible with survival to implantation, monosomy for the smallest mouse autosome, chromosome 19, was lethal at the early to mid-blastocyst stage. This lethality did not seem to be the result of the expression of recessive lethal genes.

Table 1 Frequency of aneuploid preimplantation mouse embryos

Chromosome	Day	No. of embryos		
ICR females		Total	Monosomic	Trisomic
1	3	19	3(16%)	3(16%)
	4 all	54	5(9%)	9(17%)
	in vivo	13	1(8%)	2(15%)
	in vitro	41	4(10%)	7(17%)
12	3	72	10(14%)	11(15%)
	4 *in vitro*	38	5(13%)	5(13%)
17	3	23	2(9%)	5(22%)
	4 *in vivo*	48	4(8%)	6(13%)
19	3	116	21(18%)	23(20%)
	4 all	194	3(2%)	46(24%)
	in vivo	65	0(0%)	15(23%)
	in vitro	129	3(2%)	31(24%)
C57BL/6J females				
19	3	55	9(16%)	11(20%)
	4 all	84	1(1%)	16(19%)
	in vivo	16	0(0%)	4(25%)
	in vitro	68	1(1%)	12(18%)

Aneuploid embryos were generated by mating males doubly heterozygous for two Robertsonian translocations[5,6] to superovulated ICR-Swiss or C57BL/6J females. The following male stocks were used: Rb1Bnr/Rb10Bnr for aneuploidy of chromosome 1, Rb5Bnr/Rb9Bnr for chromosome 12, Rb11Rma/Rb1lem for chromosome 17 and Rb 163H/Rb1Ct for chromosome 19. Preimplantation embryos were obtained on the third (day 3) or fourth (day 4 *in vivo*) day after observation of the plug (day 0). Day 4 *in vitro* embryos were obtained by culturing[9] day 3 embryos for 24 h. The embryos were karyotyped as before[17].

Table 2 Development of aneuploid day 3 embryos from ICR × Rb163H/Rb1Ct matings

Karyotypes	Total no.	Stage of development reached: 8–16 cells	Late morula	Early blastocyst	Blastocyst
Normal	18		9	8	1
Trisomy 19	6	1	2	3	
Monosomy 19	6			3 2	1
Undeterminable	10		7	1 2	

Day 3 embryos were scored for development and then karyotyped as previously described[17].

Mouse embryos aneuploid for chromosomes 1, 12, 17 and 19 were generated by the double metacentric technique[5,6]. Because of indications[5,7] that most monosomic embryos do not survive much beyond implantation, we used preimplantation embryos for our initial studies. The frequencies of aneuploid embryos were analysed on days 3 (late morula/early blastocyst) and 4 (late blastocyst) of development (Table 1). In each case, the doubly heterozygous parent was the father. For each of chromosomes 1, 12 and 19, the frequencies of monosomy and trisomy were virtually the same on day 3 and varied from 14 to 20%. Therefore, for these three mouse chromosomes we conclude that there is no selection against nullisomic sperm, that equal numbers of monosomic and trisomic gametes are produced at fertilisation and that the survival of monosomics to day 3 is relatively normal.

The situation was different on day 4. While the frequencies of trisomies 1, 12 and 19 and monosomy 12 each remained about the same as on day 3, the frequency of monosomy 1 had decreased somewhat and that of monosomy 19 had decreased considerably, from 18 to 2%. This loss of embryos lacking chromosome 19 occurred both *in vivo* and *in vitro*. When day 3 embryos were cultured overnight, a significant number of them died and the frequency of monosomy declined to 2% (Table 1). However, no viable monosomics were found among embryos obtained directly on day 4 (Table 1), and the inviability of monosomy 19 cannot therefore be attributed to some increased sensitivity to *in vitro* culture conditions. There were too few chromosome 17 aneuploids to draw firm conclusions about their overall viability. Nevertheless, the data suggest that at least some monosomics are viable to the late blastocyst stage.

The day 3 embryos listed in Table 1 were a mixture of late morulae and blastocysts. Because the transition between morula and blastocyst is particularly sensitive to various agents, including α-amanitin[8] and bromodeoxyuridine[9], and is the time when development stops in embryos homozygous for the t^{12} mutation[10], we investigated whether it was affected by monosomy 19. Day 3 embryos were scored visually and then karyotyped (Table 2). Both normal and trisomic embryos consisted of approximately equal numbers of late morulae and early blastocysts. Similarly, half of the identified monosomics had also blastulated, while it was not clear whether the rest had blastulated. Thus

0028-0836/79/280144—02$01.00
© Macmillan Journals Ltd 1979

blastulation itself does not appear to be the vulnerable step in monosomy 19, but the period immediately after does.

One possible explanation for the very early lethality of monosomy 19 is that a recessive allele, able to cause death before implantation, becomes uncovered in the monosomic state. Although the only chromosome 19 present in the embryos is that derived from the normal but outbred ICR Swiss parent, this does not seem likely. A very high frequency of such a lethal allele would be necessary to explain the death of all the embryos monosomic for chromosome 19. This would, in turn, result in the death of many normal embryos at the blastocyst stage, but there was no evidence for significant lethality among the hundreds of day 3 ICR blastocysts surviving in culture to day 4. Nevertheless, to obtain further evidence against the recessive lethal hypothesis, double metacentric-bearing males were mated with inbred C57BL/6J females and the progeny were scored as before (Table 1). Again, approximately equal numbers of monosomics and trisomics were observed on day 3, but as before, virtually no monosomic embryos survived to day 4. Therefore, we conclude that the lethality of monosomy 19 is an inherent property of the aneuploid state itself and does not depend on the hemizygous expression of recessive lethal alleles.

Data complementary to ours have been published by Dyban and Baranov[11]. After 3 days of development, no embryos monosomic for chromosome 5 or 17 were found. The proportions of embryos monosomic and trisomic for chromosomes 15 or 19 were the same, but both types of monosomics were retarded in development and had low cell numbers.

Chromosome 19, which comprises only 2.7% of the haploid set by length, is the smallest of the mouse chromosomes, and trisomy 19 is the trisomy associated with the greatest survival and the only one compatible with viability beyond term (Table 3)[12]. Survival of trisomies 1, 12 and 17 is much more limited[13]. By contrast, of the four monosomies studied, monosomy 19 is clearly the most lethal. Therefore, there does not seem to be any reciprocity between the viability of the monosomies and of the corresponding trisomies. Likewise, from the data in Table 3 and the more extensive data obtained by others from human trisomic embryos[14,15], there is no obvious relationship between the overall size of a chromosome and the survival of embryos which are aneuploid for it[16]. Although it has been suggested that there is an inverse correlation between the viability of specific human trisomics and the amount of active chromatin, as judged from Giemsa negative or R-band positive regions in the chromosomes involved[14], such a relationship does not exist for the mouse aneuploids discussed here (Table 3). We conclude therefore that the ultimate effect of each specific aneuploidy, and particularly of the monosomies, is as much, if not more, a function of the particular loci affected than of the total number of genes or amount of chromatin present on the chromosomes.

We thank Professor Alfred Gropp for mouse stocks and Drs Terry Magnuson and Janet Sawicki for assistance. This work was supported by the NIH (grant GM-24309) and the National Foundation–March of Dimes. C.J.E. is an investigator of the Howard Hughes Medical Institute.

Table 3 Relationship of survival of aneuploid mouse embryos to chromosome length and Giemsa light banding content

Chromosome	Length (% of haploid set) Total	Giemsa light bands	Survival (d) Monosomics	Trisomics
1	7.2(2.7)	3.1	≥4	14–15
12	4.6(1.8)	2.2	≥4	14–17
17	3.7(1.4)	1.3	≥4	10–12
19	2.7(1.0)	1.0	3.5	≥19

Chromosome lengths are as reported by Nesbitt and Francke[18], and the lengths of the Giemsa light band regions are calculated from Fig. 1 of the same report. The figures in parentheses are the ratios of chromosome lengths to the length of chromosome 19. The survivals of the trisomic embryos are as reported by Gropp *et al.*[13] and White *et al.*[12], and of the monosomics as reported here.

Selective suppression of IgE antibody responsiveness by maternal influence

IMMUNOGLOBULIN E antibodies are produced in two circumstances: by all normal animals in infections with helminth parasites[1,2], and by certain individuals against common environmental substances[3]. In these latter 'atopic' individuals, immediate hypersensitivity reactions mediated by IgE are responsible for various disorders, which in man include hay fever, allergic asthma and allergies to foods and drugs. It is known that the antibody response of the young animal may be reduced or enhanced by maternal immunisation[4–9]. We have examined the antibody response of rats immunised with egg albumin (EA) and show here that both these effects can occur together: suppression of the IgE antibody response may occur against a background of enhanced total antibody responsiveness in the offspring of immunised mothers.

Our study was originally stimulated by observations that animals including man can occasionally be born hypersensitive or with specific IgE antibody in the cord blood[10–13]. As IgE does not cross the placenta[14] its presence in the neonate indicates fetal synthesis following *in utero* stimulation with antigen. We reasoned that suppression of IgE response could also result from such an antigenic stimulus and might in fact be a more frequent occurrence. Consequently, we fed or injected rats during pregnancy and lactation with different quantities of EA given without adjuvant. In this way, the mother would act merely as a vehicle for conveying antigen to the fetus without herself producing an IgE response, as this requires that the inducing dose of antigen be administered together with an adjuvant[15]. We found that such treatment of the mothers did not have any influence on the subsequent IgE responsiveness of the offspring.

These experiments, however, led to others in which we examined the effect of immunising rats with antigen and adjuvant long enough before a pregnancy to allow the development of an immune response. Prospective mothers were immunised with either 10 mg or 10 μg EA together with *Bordetella pertussis* as adjuvant 1 month before mating (Fig. 1). These doses of antigen had previously been shown to generate two different types of response: namely, specific IgE response in the rats

0028–0836/79/280145—03$01.00

© Macmillan Journals Ltd 1979

immunised with the lower dose and superimposed specific IgE suppression in those immunised with the higher dose[15,16].

The results show that the offspring of the mothers immunised with either dose had a greatly depressed IgE response to EA. Feeding EA during pregnancy did not influence the subsequent IgE responsiveness of the progeny. Similarly, injection of the mothers with adjuvant alone was without effect.

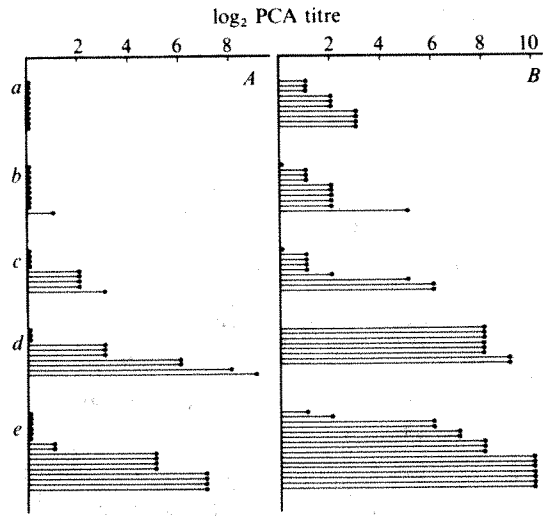

Fig. 1 The effect of preimmunisation of female rats or of feeding antigen during pregnancy on the specific IgE antibody responsiveness of the offspring. Outbred female Hooded Lister rats (Animal Suppliers) weighing 150–200 g were immunised 1 month before mating with the indicated amounts of egg albumin (EA) (Sigma grade V) injected intraperitoneally in 0.15 M NaCl together with a suspension of 10^{10} heat-killed *B. pertussis* as adjuvant. In addition the rats of groups *b*, *c* and *d* received EA in the drinking water at 10 μg ml^{-1} for 10 d starting 9 d after mating. Animals of a group immunised with 10 μg EA without additional antigen feeding did not become pregnant. The female offspring (two to three litters per group), which were born within 5 d of each other, were immunised with 10 μg EA + *B. pertussis* 6 weeks after the birth of the last litter and were challenged with 1 μg EA 35 d later. Blood for antibody assay was collected by severing the tip of the tail. IgE antibodies were estimated by the passive cutaneous anaphylaxis technique as previously described[16]. The figure shows the primary and booster IgE responses of the individual animals 12 d after immunisation (*A*) and 4 d after challenge (*B*). The times of bleeding were determined by previous observations on the kinetics of these responses in Hooded Lister rats[15]. Treatment of mothers: *a*, Immunised with 10 mg EA 1 month before mating. *b*, Immunised with 10 mg EA 1 month before mating and EA in the drinking water during pregnancy. *c*, Immunised with 10 μg EA 1 month before mating and EA in the drinking water during pregnancy. *d*, EA in the drinking water during pregnancy. *e*, No treatment.

The suppression of IgE responsiveness was antigen specific. This was demonstrated by inoculating the offspring of EA-immunised or normal mothers with both EA and keyhole limpet haemocyanin (KLH). The IgE response to EA but not to KLH was depressed in the offspring of the EA-immunised mothers.

To determine whether the suppressive effect was transferred transplacentally or in the milk, the offspring of EA-immunised and untreated mothers were exchanged on the day of birth. The IgE response of these rats following immunisation at 5–6 weeks of age was compared with that of rats reared by their natural mothers. As shown in Fig. 2 the IgE response to EA was suppressed in the offspring of normal rats if suckled by previously immunised mothers whereas the IgE response was normal in the offspring of immunised mothers fostered to non-immunised mothers. This indicated that the factors responsible for suppression were transferred in the milk. When further litters were cross-fostered at 1 or 2 weeks of age, specific suppressive factors from the immunised mothers were found to be transferred during the entire period of lactation. Thus, if the offspring of normal mothers were suckled by immunised mothers for even 1 week (from days 15–21 of lactation) a significant degree of suppression was transferred.

Assessment of diminished antibody response in the progeny of immune mothers—by measuring total antibody or numbers of antibody-producing cells, or by observing functional effects such as vaccination failure—has hitherto been made without reference to possible differential action on antibody class. To determine whether the suppression we had observed in the offspring of immunised mothers was selective for IgE or merely a facet of a generally suppressed response, we measured the IgG response and total antigen-combining capacity for EA in the sera of normal and IgE-suppressed offspring. The results in Table 1 show that higher levels of IgG and total antibody were produced in the primary response to antigen by the offspring of immunised mothers. Examination of the sera of progeny before immunisation showed that antibodies to EA (excluding IgE) were passively transferred from the immunised mother, but declined to scarcely detectable levels by 6 weeks. The additive effect of residual maternal antibody could therefore not explain the higher level of primary response seen in the progeny of immunised mothers.

Table 1 Comparison of EA IgG and total antibody response with EA IgE levels in the offspring of normal (*A*) and immunised (*B*) mothers

	IgE (geometric mean PCA titre)		IgG (mean c.p.m. $\times 10^{-3}$) (±s.d.)		Total antigen-binding capacity (mean $\log_{10}$ μg EA bound per ml serum ±s.d.)	
	A	*B*	*A*	*B*	*A*	*B*
Day 20 after immunisation	9.18	All negative	1.92 (pool)	2.93 (pool)	0.97 (0.15	1.35 (0.19)
Day 4 after challenge	1,175	All negative	4.45 (2.12)	4.71 (1.43)	1.39 (0.20)	1.47 (0.18)
Day 21 after challenge	278	All negative	3.39 (1.05)	3.72 (2.62)	1.71 (0.36)	1.49 (0.20)

IgG response to EA was measured by a paper radioallergosorbent test in which paper disks to which EA had been coupled were reacted first with serum and then with ^{125}I-labelled anti-rat IgG. The method is fully described elsewhere[19]. The antigen-binding capacity was measured by the Farr technique[20] as modified by Mitchison[21,22]. Iodination of EA was carried out with the labelled ester Bolton and Hunter reagent[23] (*N*-succinomidyl-3-(4-hydroxy, 5-^{125}I-iodophenyl) propionate; Radiochemical Centre using 5 mg EA and 1 mCi of the labelled reagent. The measurements shown were made on five serum samples from each of groups *a* and *b* rats in the experiment shown in Fig. 2. The difference between groups *A* and *B* on day 20 after immunisation in the antigen-binding assay is significant ($P < 0.01$).

Reduced antibody production in the offspring of immunised mothers has usually been attributable to maternal antibody

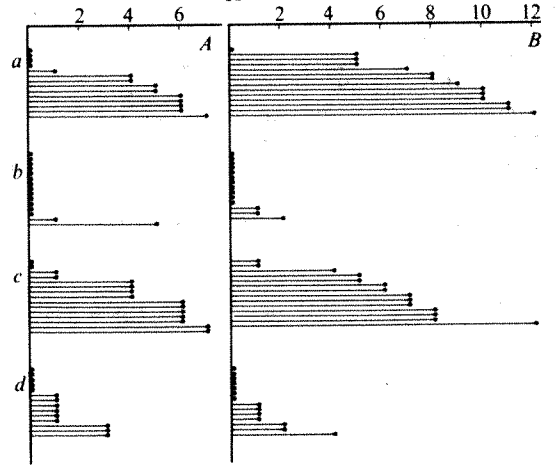

Fig. 2 Effect of cross-fostering on the transfer of the IgE suppressive effect. The immunised mothers were injected with 1 mg EA and 10^{10} *B. pertussis* 1 month before mating; control mothers were untreated. At birth the offspring were either left with their own mothers or were exchanged so that those born of immunised mothers were suckled by non-immunised mothers and vice versa. These exchanges were carried out as soon as possible and not more than 1–2 h after birth. Each of the groups *a*–*d* consisted of the female rats of four litters. These rats were immunised at 5–6 weeks with 10 μg EA and *B. pertussis* and were challenged 1 month later with 1 μg EA alone. The results shown are the primary and booster EA IgE antibody responses of individual rats. 20 d after immunisation (*A*) and 4 d after challenge (*B*). Groups: *a*, offspring of normal mothers; *b*, offspring of immunised mothers; *c*, offspring of immunised mothers fostered to normal mothers; *d*, offspring of normal mothers fostered to immunised mothers.

passively transferred transplacentally and/or in the milk according to species[17,18], although tolerance induction following encounter with antigen by the same routes has also been suggested[5,6]. We do not know the mechanism of suppression of IgE responsiveness nor whether it is related to the enhanced total antibody response. However, because a maternal immune response is necessary the phenomenon must be mediated by immune factors.

Maternal immunity transferred to the offspring for protection against infection may also interfere with the development of active immunity. The latter can be seen as a side effect, a price to be paid to ensure the survival of the neonate. However, transfer of IgE suppression from mother to young can be regarded as an objective. For, whatever the biological role of IgE, a response to substances such as pollens or foods apparently leads only to a deleterious hypersensitivity. To control such aberrant production, elaborate and sensitive immunoregulatory mechanisms have been evolved. The existence of an allergy-protective device involving specific IgE suppression by maternal influence is an additional possibility which must now be considered.

We thank Torbjörn Karlsson and Hans Bennich for the IgG antibody measurements, Roger Parton for the *B. pertussis* and Alison Flannigan for technical assistance. The work was supported by the MRC, the Wellcome Trust and by INSERM (France). E.J. is a Locke Research Fellow of the Royal Society.

T cells primed by influenza virion internal components can cooperate in the antibody response to haemagglutinin

THE fact that nude mice produce significantly lower titres of antibody to influenza haemagglutinin than do normal mice implies that this response is T-cell dependent[1,2]. Further evidence of cooperation between T and B cells has been provided by the immune response of mice to purified haemagglutinin[3]: a greater production of strain-specific, but not of cross-reactive, antibody was observed in the presence of haemagglutinin-primed T cells. We report here that the antibody response to haemagglutinin can also be enhanced by T cells primed by the internal components of the influenza virus. This may provide an explanation for previous findings[4–6] that infection with one influenza subtype may influence the subsequent response to another which does not cross-react serologically.

Table 1 X31 HAI antibody response of mice after antigen priming

Priming antigen	Boosting antigen	$\log_2$ serum HAI titre ± s.e.m. Day 4	Day 10
—	X31 Virus	≤1.58*	2.38 ± 0.49
X31 Spikeless particles	X31 Virus	4.98 ± 0.93	5.38 ± 1.07
—	X31 Monomer HA	≤1.58	2.33 ± 0.75
X31 Spikeless particles	X31 Monomer HA	≤1.58	≤1.58
X31 Spikeless particles	X31 Spikeless particles	≤1.58	≤1.58

Groups of five CBA/T6 mice were primed by i.p. injection of 100 μg *B. pertussis* plus 10 μg antigen as stated. After 28 d the mice were boosted by i.p. injection of 10 μg antigen and bled 4 and 10 d later.
* Limit of assay: no antibody detectable.

Treatment of the X31 strain of A/Hong Kong/1/68 influenza virus (ref. 7) with the protease bromelain removes the haemagglutinin and neuraminidase subunits from the surface of the virion and leaves the particles smooth-surfaced[8]. Spikeless particles prepared in this way were injected intraperitoneally (i.p.) into 12-week-old CBA/T6 female mice together with *Bordetella pertussis* (Wellcome). When subsequently injected i.p. with purified X31 virus, mice primed with spikeless particles gave a much higher and earlier haemagglutination inhibition (HAI) antibody response than did controls that had been injected with *B. pertussis* alone (Table 1). In contrast, the response to bromelain-extracted monomer haemagglutinin[8] was not enhanced by priming with spikeless particles. There was also no HAI antibody response to a second injection of spikeless particles. Similar results were obtained from preliminary experiments using deoxycholate-treated virus as the priming antigen. This preparation lacks both envelope lipid and surface glycoproteins but contains all the internal proteins and RNA of the virus[9]. These results suggest that the priming effect is unlikely to be mediated by otherwise undetectable traces of haemagglutinin remaining in the X31 spikeless particle preparation.

Mice primed with X31 spikeless particles and then injected with A/Puerto Rico/8/34 virus gave an enhanced HAI antibody response to this subtype (Fig. 1*a*), even though the H_3 haemagglutinin of X31 is antigenically distinct from the H_0 haemagglutinin of A/PR/8/34. The HAI antibody response of mice to B/Victoria/70 was not influenced by priming with X31 spikeless particles (Fig. 1*b*), indicating that the priming is type specific.

The cell type responsible for the priming effect was investigated using a spleen cell transfer technique (Table 2). Recipient mice given 10^8 unfractionated spleen cells from primed donors were able to mount an enhanced response after i.p. injection of X31 virus. Ig-negative spleen cells separated by the rosette method, which removes more than 97% of Ig-bearing cells as detected by autoradiography[10], were also effective; 2×10^7 Ig-negative spleen cells were capable of substituting fully for 10^8 unfractionated cells. Smaller quantities were progressively less effective, but still produced a measurable improvement in antibody response. We have not found it necessary to irradiate the recipient mice in our adoptive transfer experiments. This may be because relatively few primed cells are required. It may also reflect a more general property of the virus, as successful adoptive transfer of influenza immunity using normal recipients has previously been reported[11,12].

Our findings strongly suggest that cell cooperation analogous to that seen in the carrier–hapten phenomenon[13–15] occurs in the antibody response to influenza haemagglutinin. Thus, T cells recognising some internal component of the virion are capable of cooperation with B cells in the production of HAI antibody. Work in progress indicates that of the internal components at least the matrix protein is recognised by cooperating cells (Table 3). The mechanism by which associative recognition of the haemagglutinin and internal proteins can occur is unclear. The haemagglutinin spikes are present on the virus surface and do not seem to penetrate the lipid envelope, whereas the matrix protein, the outermost of the internal components, is contained within the lipid envelope and is thought not to penetrate the bilayer to the virion surface[16]. The two proteins are therefore connected and also separated by the lipid bilayer. Thus, for recognition and cell cooperation to occur, either the matrix protein is more accessible than described above or some processing step may be necessary to present both proteins in association on the surface of a macrophage or other cell.

In this latter case, the mechanism of help is similar to that of the associative recognition of intrinsic cell surface proteins described by Lake and Mitchison[17]. In their terminology this type of effect could be described as intermolecular, intrastructural help, as both helper and principal determinants are carried by different proteins. Our data then provide an example of cell-surface associative recognition in which both antigens are of viral origin.

It has been reported that the HAI antibody response of ferrets, hamsters and mice to inactivated influenza vaccines can be enhanced by prior heterotypic infection[4,5] and even that infection can provide a partial heterotypic immunity[6]. Our results may help to explain these otherwise puzzling phenomena.

Table 2 Adoptive transfer of the priming effect by Ig-negative cells

Donor cells	$\log_2$ serum HAI antibody titre ± s.e.m. Day 4	Day 10
—	≤1.58*	5.78 ± 0.58
1×10^8 Normal spleen cells	≤1.58	4.78 ± 0.37
Primed spleen cells:		
1×10^8 Unfractionated	3.98 ± 0.24	5.98 ± 0.24
2×10^5 Ig-negative	3.58 ± 0.00	5.98 ± 0.51
2×10^6 Ig-negative	3.78 ± 0.20	5.78 ± 0.37
2×10^7 Ig-negative	4.78 ± 0.20	6.33 ± 0.25

Groups of five normal CBA/T6 female mice were injected with spleen cells from donors primed 28 d earlier with 10 μg X31 spikeless particles. Spleen cells were fractionated by the rosette method[10]. Recipients were boosted with 10 μg X31 virus and bled 4 and 10 d later.
* Limit of assay: no antibody detectable.

Table 3 Ability of purified matrix protein to prime helper cells

Priming antigen	$\log_2$ serum HAI antibody titre ± s.e.m. Day 4	Day 11
—	≤1.58*	4.58 ± 0.77
X31 Spikeless particles	4.30 ± 1.12	6.38 ± 0.37
Matrix protein	3.98 ± 0.68	7.18 ± 0.51

Groups of five CBA/T6 mice were primed by i.p. injection of 100 μg *B. pertussis* plus 10 μg antigen as stated. After 28 d the mice were boosted by i.p. injection of 10 μg purified X31 virus and bled 4 and 11 d later. Matrix protein was derived from A_2/Jap/305/57 × A_0/Bel/42 (H_2N_1), prepared by the method of Laver[18]. SDS-polyacrylamide gel electrophoresis gave a single distinct protein band.
* Limit of assay: no antibody detectable.

We thank Drs Colin Brand and J. J. Skehel for the virus preparations used in this study, and Barbara Pearce and Martin Trowbridge for technical assistance.

Use of cyclosporin A in allogeneic bone marrow transplantation in the rat

ALLOGENEIC bone marrow transplantation (BMT) has become the therapy of choice for the treatment of severe aplastic anaemia and severe combined immunodeficiency diseases and is considered beneficial for the treatment and possible cure of malignant diseases, especially lymphohaematopoietic malignancies[1]. Several serious complications, however, prevent the full realisation of the therapeutic potential of this procedure. To accept an allogeneic marrow graft, patients (even those treated for aplastic anaemia) have to be conditioned with cytoreductive agents like cyclophosphamide (Cy) or total body irradiation (TBI), agents that have relatively low therapeutic indices for immunosuppression and marked toxicities. Furthermore, patients, even if matched with their respective donors at the major histocompatibility complex (MHC), have after engrafting successfully, a high incidence of potentially fatal graft-versus-host disease (GvHD). Third, patients, who successfully engraft have a severe immunodeficiency for several months after transplantation that apparently contributes to potentially fatal

Groups of Lewis rats were treated with busulphan 30 mg per kg i.p. alone (groups 1, 2 and 3) or together with cyclophosphamide 150 mg per kg i.p. (group 5), a short course of rabbit anti-rat-thymocyte serum i.p. (RARTS, 1.5 ml daily from day −8 to day −2) (group 4) or Cs A (25 mg per kg given subcutaneously daily from day −8 to day +18) (group 6). One day after busulphan administration 60×10^6 nucleated marrow cells were given intravenously. Cumulative mortality, fraction of animals proven to be chimaeras and fraction of animals with clinical signs of GvHD are recorded. Chimaerism was established by typing the peripheral lymphocytes with strain-specific cytotoxic antisera. NT, Not tested.

opportunistic infections in the post-grafting period[2]. Attempts to overcome these complications have had only limited success. Cyclosporin A (Cs A), an undecapeptide of fungal origin[3], has been reported to have very profound antilymphocytic activities with very low degrees of myelotoxicity[4]. It has been shown to suppress a variety of humoral and cellular immune phenomena[5], including the rejection of renal allografts in rabbits.[6] It seemed reasonable, therefore, to study its effects in an animal model of bone marrow transplantation. Cs A permits the full establishment of a rat marrow graft across the major histocompatibility barrier. Given post grafting it prevents GvHD in an AgB mismatched donor–recipient combination and allows recovery of T-dependent immune functions as early as 28 d after transplantation. Thus, Cs A seems to be a promising agent for use in clinical marrow transplantation.

We have chosen an allogeneic rat system that we have found particularly useful as a preclinical model for human BMT[7]. Lewis rats (Ag-B1) were given a lethal dose of busulphan (BU), a drug that is not immunosuppressive in this species but myelotoxic, leading to the death of the animals from marrow failure unless protected with syngeneic marrow[8]. ACI (Ag-B4) marrow which is different at the MHC, will not be accepted by these BU-treated animals, unless they are immunosuppressed with high doses of Cy or rabbit anti-rat thymocyte serum (RARTS)[9]. If Cs A is substituted for Cy or RARTS and given as a daily injection of 25 mg per kg subcutaneously for 28 d, the animals will accept a bone marrow graft across the major histocompatibility barrier and become healthy chimaeras as evidenced by typing on day 21 (Table 1). The animals furthermore accept skin grafts from donor- and recipient-type animals (ACI and Lewis) but reject a third party (BN) skin graft. These data suggest that Cs A is able to provide the necessary immunosuppression to allow the establishment of a functional, histoincompatible marrow graft in an animal that suffers from a presumed lethal, BU-induced marrow aplasia.

An immunosuppressive drug like Cs A, that has been claimed to induce specific immunological tolerance[10], should have a marked potential for the prevention and treatment of GvHD, a disease considered to result from an immunological attack of immunocompetent donor T cells against host target tissues[11]. This disease can be studied with relative ease in the rat bone marrow transplantation model, where a clinical syndrome consisting of weight loss, marked dermatitis, diarrhoea and general unkempt appearance can be easily recognised, especially when a histoincompatible donor–recipient combination is used[12]. All Lewis rats, conditioned with 1,000 rad TBI and infused with AgB-incompatible ACI marrow cells, developed severe GvHD within 12 d and showed a mortality of 75% (6 out of 8) by 35 d post-transplantation. Subcutaneous daily injections of Cs A starting 1 d post-transplantation and maintained until day 18 completely prevented the development of GvHD as judged by clinical observation, and by histological examination of the skin on days 14, 17, 21, 28, 35, and of tongue, liver and intestine on days 21 (Fig. 1), 28 and 35. These Cs A-treated animals have now survived more than 50 d post-transplantation without any signs of clinical GvHD and seem to be in excellent health. The peripheral lymphocytes of these chimaeras were shown to be of donor (ACI) origin with the use of specific cytotoxic typing sera[12]; furthermore, they accepted donor- and recipient-type skin grafts but rejected third party (BN) skin allografts in a normal fashion, fulfilling the criteria for operational tolerance.

Borel *et al.*[5] have used Cs A to affect GvHD in a rat bone marrow transplant model, and have shown that oral administration of Cs A merely delayed the onset of lethal GvHD in a parent-to-hybrid situation. The complete prevention of GvHD clinically and histologically seen in our study could be due to the different donor–recipient combination (although we used the most histoincompatible one available to us) but might alternatively be due to the higher doses of Cs A applied, the route of administration (parenteral compared with oral), or the duration of administration.

In previous studies[13] we have evaluated the immune status of rat chimaeras transplanted with allogeneic histoincompatible bone marrow and noted a marked immunodeficiency. Such animals failed to demonstrate delayed type hypersensitivity (DTH) at 40 d post-transplantation and showed poor antibody responses to sheep red blood cells (SRBC)[14]. This defect has been described in other animal systems and in man[15] and is

Table 2 Immune recovery of marrow transplant recipients after Cs A treatment

Donor–recipient combination	ACI*/Lewis	ACI*/Lewis, Cs A†	Lewis‡/Lewis
Relative reconstitution of lymphoid tissue	($n = 4$)	($n = 4$)	($n = 4$)

Groups of Lewis rats (16 per allogeneic group, 8 per syngeneic group), were given 1,000 rads TBI and injected with 60×10^6 nucleated ACI* or Lewis‡ marrow cells i.v. One group of rats† was, in addition, given Cs A 25 mg per kg s.c. daily for 18 d starting 1 d after marrow infusion. Four animals out of each group were killed at day 21 (days 28 and 35 in the Cs A-treated group) and the lymphoid organs examined histologically. The relative number of lymphocytes in the lymphoid tissues are rated on a 0 to 4+ scale with 4+ being that of a normal Lewis rat. Surviving animals were immunised i.v. with 1 ml 10% solution of SRBC and the saline agglutination titres determined 1 week later.§ In addition, the animals were sensitised to DNCB (600 $\mu g\ ml^{-1}$ over 1 cm^2 skin) on day 28, challenged on day 42 (60 $\mu g\ ml^{-1}$ over 1 cm^2 skin) and biopsied on day 44. The delayed type hypersensitivity reation was graded on a 0–4+ scale, 4+ being the reaction of a normal Lewis rat.

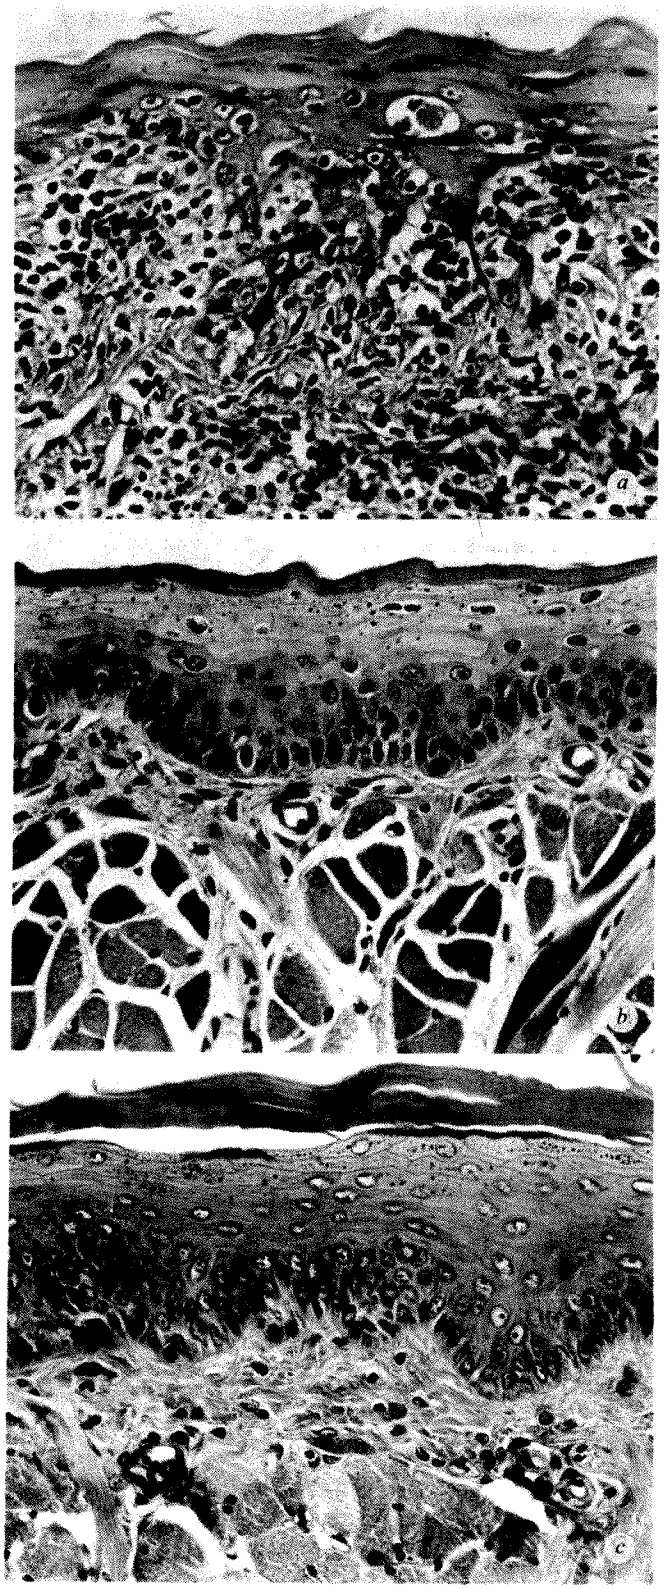

Fig. 1 Effect of Cs A on the development of GvHD in the rat. Lewis rats were given 1,000 rad total body irradiation (dual source ^{137}Ce small animal irradiator delivering 136 rad per min) followed in 24 h by infusion of 60×10^6 ACI (groups *a* and *b*) or Lewis nucleated marrow cells (*c*). Group *b* was treated in addition with Cs A given daily subcutaneously in a dose of 25 mg per kg from day +1 through day +18 post-transplantation. Four animals of each group were killed 28 d post-transplantation and autopsies performed. A representative section of the tongue is shown (haematoxylin and eosin, ×400). A graft-versus-host reaction is recognised in the allogeneic group (*a*), which did not receive Cs A. No histological difference can be seen between Cs A-treated allogeneic chimaeras (*b*) and rats given syngeneic marrow (*c*).

Fig. 2 Effect of Cs A on lymphocyte repopulation in the thymus of allogeneic marrow graft recipients. Lewis rats, conditions with 1,000 rad total body irradiation and infused with ACI (*a* and *b*) or Lewis (*c*) marrow, were either non treated (*a* and *c*) or treated (*b*) with Cs A (see Table 2). The thymuses of the animals were examined histologically (stained with haematoxylin and eosin, ×200). Cs A-treated rat chimeras show good reconstitution of the thymic cortex (*b*), with medium and small lymphocytes, occasional lymphoblasts and mitotic figures. These lymphoid cells were shown by cytotoxic typing analysis to be of ACI (donor) origin. The untreated syngeneic recipients have reconstitution of the cortex with small lymphocytes and have a distinct corticomedullary junction.

considered to contribute to a significant degree to the impaired defence of the host against opportunistic infections post-transplantation[16], especially those leading to an often fatal interstitial pneumonitis[17]. The aetiology of this immune defect is poorly understood, but might be related to graft-versus-host reactions, as the degree and length of immunodeficiency post-transplantation correlate with the degree of histoincompatibility between donor and recipient[18].

As GvHD was prevented in our rat model by Cs A we evaluated the immune status of the resulting chimaeras morphologically and functionally. Lewis rats were conditioned with TBI and given syngeneic marrow, allogeneic (histoincompatibile ACI) marrow and allogeneic (ACI) marrow plus Cs A daily for 18 d, starting on day 1 post-transplantation. Representative animals out of each group were killed on day 21 (days 28 and 35 in the Cs A-treated group) and the lymphoid organs examined histologically. The striking repopulation of the T-cell areas in the lymphoid organs of allogeneic Cs A-treated chimaeras (Fig. 2) correlates with a recovery of immunological function (Table 2). Cs A-treated chimaeras immunised with DNCB and injected with SRBC were capable of mounting an immune response against SRBC and showed DTH, in striking contrast to the immunodeficient allogeneic chimaeras not treated with Cs A.

At present it is unclear how Cs A induces specific tolerance without interfering with the immune reconstitution. Studies by Green and Allison[6] have shown that Cs A seems to act on lymphoblasts with both T- and B-cell markers and presumably eliminates or suppresses clones of lymphocytes responding to the antigens in question. The operational tolerance which we have in our Cs A-treated allogeneic chimaeras would then have been caused by a specific deletion or inactivation of clones of donor cells responding to host target antigens according to the clonal selection theory of transplantation tolerance. On the other hand, we and others have shown that transplantation tolerance might be induced and maintained by donor-type suppressor cells[14,15,19,20]. It is tempting to speculate that Cs A acts by accelerating the appearance of suppressor cells, and indeed we have found in preliminary experiments that Cs A-treated allogeneic chimaeras possess cells in the spleen as early as 21 d post-transplantation, which suppress mixed lymphocyte reactions between donor- and recipient-type cells (data not shown). If these findings can be confirmed in future experiments, we might have a better understanding of the mechanism of action of this new drug and of the mechanism of transplantation tolerance as well.

Our studies seem to indicate that the optimism for Cs A generated from studies in other animal systems is justified. In our rat system this drug proved as immunosuppressive as Cy or RARTS, prevented GvHD and allowed early recovery of the immune function post transplantation. Cs A therefore seems to be a promising agent for use in clinical BMT.

We thank Mrs L. Smith and Mrs C. Webster for assistance. The drug was supplied by the Pharmaceutical Division of Sandoz Ltd, Basle, Switerland. This work was supported by an ACS grant (no. CH-113) and an ACS Institutional Research grant (nos IN-11P and CA-15396)

Degranulation capacity of cultured mast cells in the presence of histamine releaser

A PURE population of mast cells develops when suspensions of lymphoid cells prepared from mice pre-immunised with horse serum are grown on embryonic mouse skin fibroblast monolayers[1]. These *in vitro* matured mast cells are capable of undergoing repeated cycles of degranulation and regeneration[2]. Both IgG_1 antibody and the corresponding antigen and the compound 48/80 (ref. 3) trigger degranulation of more than 90% of the mast cells, releasing 80 to 90% of their histamine content[2]. This produces an immediate effect on the cells in the fibroblast monolayer. The well-stretched cytoplasm is displaced, opening numerous 'windows' scattered over the whole monolayer[2]. These capacities of cultured mast cells raise questions on the relationships between them, the degranulating agent and the degranulating products released into the medium. Using our tissue culture, mast cell behaviour can be studied in the continuous presence of the degranulating agent or of the degranulating products. We show here that mast cells regenerate degranulation irrespective of the continuous presence of the histamine releaser compound 48/80, but they become unresponsive to its degranulating effect, although they are totally degranulated by IgG_1 and the corresponding antigen.

The first experiments compared the behaviour of the mast cells grown: (1) in the continuous presence of 48/80 and the degranulating products; and (2) in similar cultures but from which the medium containing the 48/40 and the degranulating products was replaced 15 min later by a fresh 48/80-free medium. No difference was observed between the two groups. After 3–5 h, the fibroblasts stretch back, the windows close and the monolayer resumes its former confluent texture, with a large number of granules spread over it. The degranulated cells start immediately to synthesise histamine at an accelerated rate, and in 3 d the amount of histamine is totally replenished (manuscript in preparation). In some cases it even surpasses the level of the control undegranulated cultures (Table 1).

To see whether the regeneration capacity and lack of degranulation activity is due to decomposition of 48/80 we transferred medium containing 48/80 after further 4 days' incubation of the mast-cell cultures (91% mast cells degranulated, and 83% of the histamine was released 15 min after addition of the 48/80) to parallel control plates containing mast cells maintained with ordinary medium. Histamine was released and windows were formed (Table 1, group B). This clearly shows that 48/80 preserves its degranulating capacity over a period of 4 d. In further experiments 48/80 was transferred every 24 h for 4 d to new mast cell plates. At the fourth transfer the percentage of degranulated mast cells dropped from 73 to 45%. To confirm that the regenerated mast cells are refractory to triggering by 48/80, we replaced the 4-d-old medium with fresh medium

0028-0836/79/280151—03$01.00

© Macmillan Journals Ltd 1979

containing 48/80 and incubated the plates for 15 min. No degranulation occurred, and a negligible amount of histamine was found in the medium (Table 1, group A). However, when the medium containing fresh 48/80 was replaced by anti-horse serum IgG_1 plus antigen there was intensive degranulation (91%) with abundant window formation and 90.3% release of histamine (Table 1, group A).

This desensitisation course was studied further by exposure to serial dilutions of 48/80. Half of the plates of each dilution were assayed for histamine release after 20 min of exposure (Fig. 1), while the other half was incubated for an additional 3 d and then re-exposed to 15 μg 48/80 for 20 min (Fig. 2). There was complete unresponsiveness in cultures incubated with ≥10 μg per ml. (Cell counts showed that the unresponsiveness was not a result of diminishing number of mast cells in the cultures.) However, mast cells degranulated by 15 min incubation with 48/80 and then maintained further for 4 d with ordinary medium were degranulated thoroughly (87%) by fresh 48/80–like the control plates maintained with the ordinary medium alone (91% degranulation) (see also Table 2).

The persistence of refractoriness of regenerated mast cells after removal of 48/80 was examined by two methods. In the first method, cultures were exposed to 10 μg of 48/80 per ml (79.8% histamine release) either for 3 d, or for only 20 min to allow the degranulation to terminate followed by fresh 48/80-free medium for 3 d. Control cultures received only fresh medium. The old medium was then removed, cultures were washed twice and fresh 48/80-free medium was added. At intervals, 1 ml of medium containing 10 μg 48/80 or IgG_1 + 1% horse serum (see Table 1 legend), was added and the percentage of histamine release was determined. The results are shown in Table 2. In this culture, incubation with 10 μg 48/80 did not produce complete desensitisation (25% histamine release). Nevertheless, it can be seen that the responsive capacity was only slightly increased after removal of 48/80 (33% and 45% release). On the other hand, the response to IgG_1 was not affected by pretreatment with 48/80 and remained high in all the experimental groups.

In the second method mast cells were degranulated by 48/80 and then maintained further in the same degranulating medium for 3 d while control plates were maintained with ordinary medium. Both groups were passaged by trypsinisation to make 3.5 new plates from each older plate. (Note that trypsin releases about 70% of the histamine[2,5].) The degranulation capacity was

Table 1 Histamine release by 48/80 and IgG_1 in mast-cell cultures grown continuously with 48/80

Experimental group	Treatment of cultures	Free histamine (μg per plate)	Histamine in cells (μg per plate)	Histamine release (%)
A	4 d with 48/80; old medium removed, fresh medium + 48/80 added for 15 min	0.72	8.44	7.9
	Anti-horse serum (IgG_1) + horse serum	7.62	0.82	90.3
B	Recipient of old medium with 48/80 from group A	10.36	3.71	*
C	Maintained 4 d with 48/80	—	8.28	—
D	Maintained without 48/80	—	7.03	—

To obtain clonal differentiation of the mast cells, lymphoid cell suspensions (prepared from mice immunised with horse serum[1,2]) were grown on fibroblast monolayers. BALB/c mice, 2–4 months old, were injected with 0.2 ml horse serum twice a week for 4 weeks. The animals were bled 6–12 d later and the serum was collected and frozen. This preparation, heated to 56 °C for 30 min to inactivate IgE, was used in inducing degranulation. The suspensions were prepared as described previously[2,5]. Cells 10^7 in 2 ml Dulbecco's medium, supplemented with 15% heat-inactivated horse serum, were plated on 35-mm plastic Petri dishes containing fibroblast monolayers, prepared by plating 2.5×10^5 embryo skin cells in 2 ml Waymouth's medium supplemented with 10% calf serum and ready for use 4–6 d later. In these cultures mast-cell clones attained maximal growth at ~15–25 d. Cultures were normally passaged once or twice by trypsinisation between the 10th and 24th days, with the trypsinised cell suspension plated to make 2 new plates from each old plate. Within 4–6 d, mature mast cells spread confluently over the monolayer. On the 19th day of culture, 20 μg of 48/80 (sigma) in 2 ml Dulbecco's medium were added to half the plates while the other half received fresh medium only. 91% of the mast cells degranulated. The cultures were incubated further for 4 d. The plates maintained with 48/80 contained 1.1×10^6 mast cells and those without it 0.9×10^6 mast cells. Histamine was titrated by Snyder's radioenzymatic assay as described previously[2]. The fluid, removed from the plate, was spun at 2,000 r.p.m. for 10 min. The supernatant was frozen pending assay of the free histamine in the medium; to the sediment, 2 ml of 0.1 M HCl was added and the whole content transferred to the plate containing the monolayer. The plates were frozen at −20° C pending assay of the histamine in the cells.

*As the medium already contained histamine, the extent of degranulation is shown by the amount of histamine retained in cells.

Table 2 Degranulation capacity of mast cells in culture after 3-d-old 48/80-containing medium was removed

Time after removal of 48/80 (h)	3 days with 48/80		Without 48/80		15 min with 48/80

72	33.5	71.5	80.0	60.0	76.6	70.6

Culture was established by plating 10^7 lymph node cells prepared from 4 month old BALB/c mice, 1 d after booster injection of horse serum. Culture was passaged 10 d later to make 3.2 new plates from each old plate. After 6 d, when there were 5.3×10^5 mast cells per plate, 20 μg of 48/80 in 2 ml Dulbecco's medium were added and the cultures were incubated for an additional 3 d. Then the medium was removed, cultures washed twice and fresh 48/80-free medium was added. At intervals the medium was removed and either 1 ml of Dulbecco's medium containing 10 μg 48/80 was added or 0.4 ml of antiserum (PCA titre in mice-1000), dilution 1:5 was added and followed 3 min later by 0.4 ml of 1% horse serum. After 20 min incubation the plates were processed for histamine assay.

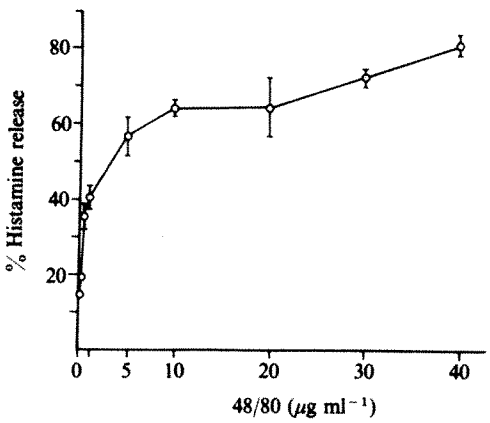

Fig. 1 Percent of histamine release as a function of dose of 48/80. A 16-d-old culture, 6 d after trypsin passage, making 3.2 new plates from each old plate. Counts of mast cells yielded an average number of 8.9×10^5 per plate. The cultures were incubated for 20 min before being processed for histamine assay.

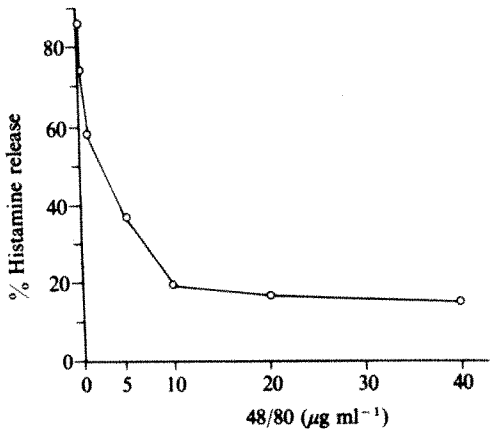

Fig. 2 Same culture as Fig. 1, but plates were incubated further for 3 d with the medium containing the various amounts of 48/80. These plates were then rechallenged with 15 μg 48/80 in 1 ml of medium. They were incubated for 20 min before processed for histamine assay.

determined immediately after plating in fresh medium and at different times thereafter. Results are shown in Fig. 3. At time zero histamine was not released, as compared to 10% in the control cultures; but the degranulation capacity gradually increased during the first 24 h, coinciding with the replenishment of the cellular histamine content until 48–72 h, when the response to 48/80 completely recovered. The study shows that without trypsinisation, restoration of the degranulation capacity was limited but virtually complete after such treatment. We presume that the refractoriness is induced by 48/80 which is bound to the cells during regeneration and detaches after trypsinisation.

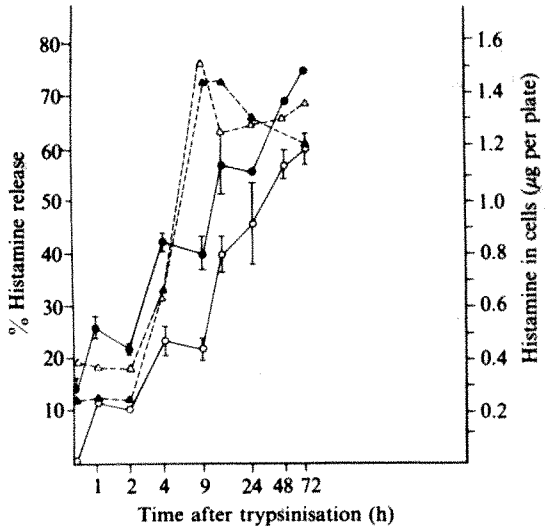

Fig. 3 Restoration of the degranulation capacity after passaging by trypsinisation and plating in 48/80-free medium. Culture was established by plating 10^7 lymph node cells prepared from 4-month-old BALB/c mice 14 d after last injection with horse serum. Culture was passaged 8 d later to make three new plates from each old plate. Seven days later, 40 μg 48/80 in 2 ml Dulbecco's medium were added to half the plates while the other half received fresh medium only. 65% of the histamine was released. The cultures were incubated further for 3 d. Then the medium was removed and trypsin solution (0.3% in Ca^{2+}- and Mg^{2+}-free phosphate-buffered saline) was added. After 20 min the cells were collected, spun down, resuspended in Dulbecco's medium and horse serum and plated in 35-mm Petri dishes to make 3.5 new plates from each old plate. At different intervals, the medium was removed and 1 ml medium containing 15 μg 48/80 was added. After 20 min the plates were processed for assay of histamine. % Histamine release: ○——○ 3 d with 48/80; ●——● 3 d without 48/80. Histamine in cells (μg): ▲----▲ 3 d with 48/80; △----△ 3 d without 48/80.

This work has revealed hitherto unknown properties of the mast cell. The new information is important in view of its role in allergy. It is clear that in the continuous presence of the histamine releaser 48/80, the cell is reversibly desensitised, an effect which possibly comes under the heading of tachyphylaxis—development of tolerance to second exposure to a drug or an agonist[6,7]. Obviously, it is still to be seen whether there is a similar response to reaginic antibodies and the corresponding allergens. Unfortunately, attempts to maintain mast-cell cultures in the continuous presence of mouse anti-horse serum plus horse serum as antigen, in dilutions optimal for total degranulation proved unsuccessful. This was probably because of the stimulation of a high metabolic rate with effects on the medium *p*H. A similar effect was obtained when such antibody–antigen complexes were added to fibroblast and macrophage cultures. This observation indicates recourse to classes and subclasses of purified immunoglobulin; thus, application of pure IgE, IgG_1, IgG_{2a} and IgG_{2b} to the different cells grown in our cultures would make it possible to assign the *in vitro* manifestation to its cause. This is important, as while both IgE and IgG_1 degranulate mast cells, they neither fix complement nor opsonise macrophages; by contrast, IgG_{2a} fixes complement and attaches to the Fc receptor on the macrophage[8].

Orderly compression of the retinotectal projection following partial tectal ablation in the newborn hamster

MANY hypotheses have been proposed to account for the development of the exquisitely specific systems of neuronal connections in the brain. Axons might read chemical labels on their target cells, attaching only to cells with a matching label[1]; axon and target cell populations might arrange a match without cell-to-cell specificity, using such mechanisms as differential advantage in competition for terminal space[2,3]; or some feature of the development and maturation of an axon and target system might produce ordered patterns of connectivity. The principal model system used to test these hypotheses has been the retinotectal projection of animals with nervous systems which are capable of regeneration, although it is not known whether this system in fact behaves like a developing nervous system. After removal of half the tectum in goldfish or frog, for example, an entire retina will compress its representation uniformly onto the remaining half tectum[4,5]. We have repeated this experiment in the developing mammalian brain, and have found that following a partial tectal ablation in a neonatal hamster, the projection from the retina to the superior colliculus will terminate in an

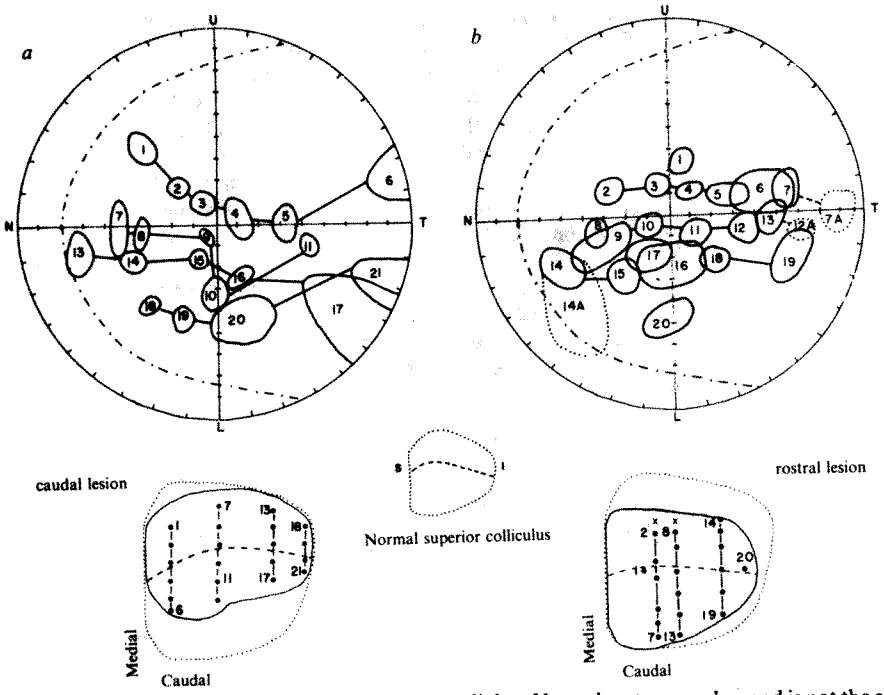

Fig. 1 Colliculi with reconstructed electrode penetrations and associated visual fields from a hamster with a neonatal lesion of the right caudal colliculus (*a*) and of the right rostral colliculus (*b*). The colliculi are shown in dorsal view; solid outlines indicate the remaining superficial gray layer in each hamster and dotted lines the normal extent of the superior colliculus. Electrode penetrations associated with receptive fields with defined borders are represented by black dots, and their corresponding numbered visual receptive fields are shown in the visual field diagram above. For visual convenience rostral to caudal series of penetrations and corresponding nasal-to-temporal visual receptive field are connected with lines. Medial colliculus, where upper visual field is represented, was not explored because of occlusion by the vein of Galen. The two penetrations marked by crosses were associated with diffuse receptive fields in the upper nasal quadrant including, but not limited to, the receptive field with the appropriate topographical position. The map of the visual field is centred about the projection of the optic disc. The broken line (- · - · -) indicates the perimeter of the visual field in normal hamsters. The nasal (N) to temporal (T) axis is determined by the projections of the attachments of the medial and lateral rectus muscles, and is not the same as the horizontal plane defined by gravity. The orthogonal upper (U) to lower (L) axis is defined by the insertions of the superior and inferior rectus muscles. This superior–inferior axis, which divides the visual field into nasal and temporal halves, is shown projected on the surface of a normal superior colliculus (centre inset) and both damaged colliculi as a dashed line (– – –). Dotted receptive fields indicate fields found deep to the surface of the superior colliculus.

orderly way in a smaller than normal tectal volume, as in goldfish and frog[1-4]. However, we have found preferential representation of nasal visual field which has not been reported in studies of non-mammalian animals in which the optic tract axons can regenerate. This may suggest some fundamental differences in developing and regenerating systems; in any case, it poses new problems for theories of neuronal specificity in developmental neurobiology.

On the day of birth, the brain of the hamster is quite immature. The first fibres from the retina have grown to the superior colliculus, entering the structure at its rostral border[6]. Although some axonal end arbors may already have begun to form near the tectal surface, major arborisation seems to begin around day 3, with the caudal, medial and lateral margins lagging behind rostral and central colliculus. An adult-like pattern and density is found by the age of 12–14 d. Partial lesions made in the colliculus on the day of birth thus intercept the initial stage of tectal innervation, and major reorganisations of retinal projection patterns do occur[7-9].

The superior colliculus is a prominent structure in the newborn hamster, and its superficial layers may be destroyed directly through the thin cranium by local application of heat[7-9]. In 15 newborn hamsters partial lesions of the colliculus were inflicted on the day of birth by this method. After surgery, the animals were returned to the mother and allowed to mature normally. When these animals had reached the age of at least 2 months, the topography of the retinotectal projection was assessed electrophysiologically[10,11], and the extent of the neonatal lesion was determined thereafter by conventional histological reconstruction[7-11]. In the 15 animals studied, the surface area of the remaining intact superior colliculus ranged from 40% to 80% normal, and tissue loss was confined principally to the superficial gray layer, as determined from sectioned material.

The receptive fields associated with a series of electrode penetrations of the surface of the superior colliculus in a hamster with a neonatal lesion of the caudal part of the superficial layer are shown in Fig. 1*a*. The entire visual field was represented at the tectal surface. Multiunit receptive field sizes reflected this compression of the visual field onto a smaller tectum. The average receptive field size in a normal hamster is $8.6 \pm 0.3°$ (s.e. mean); in animals with caudal lesions average field size was $12.4 \pm 0.4°$. The topography was generally orderly, although localised mislocations or inversions were observed in this animal, as in every other. One striking anomaly was present in this and similarly prepared cases: the representation of the nasal visual field on the collicular surface was proportionately much greater than the representation of the temporal visual field (compare the positions of the superior–inferior meridian in the normal with the caudal lesion case in Fig. 1). The rostral-to-caudal extent of the nasal 70° of visual field was close to normal (75% normal length, as measured along the naso–temporal meridian). For the temporal 90° of visual field, the representation along the same meridian was only 48% of normal. This disparity in the rostro-caudal extent allotted to the nasal as opposed to the temporal visual field was present in all eight animals with caudal lesions. In three of the animals, in addition to the general compression, there was loss of 10–30° of visual field in the temporal periphery.

Lesions of rostral colliculus were made in a further seven newborn hamsters. The consequences of this lesion for axons entering the colliculus are somewhat different than the caudal lesion: axons entering the tectum must traverse an area of damaged tissue before innervating the remaining superficial gray layer. The mechanical disruption caused by this procedure may have contributed to a pattern of disorder in retinotopy observed in regions on the rostral border of the remaining superficial gray in four of the seven cases, an anomaly which has also been observed neuroanatomically[7-9]. Receptive fields of units at the rostral border were large, encompassing whole quadrants or hemifields and were topographically disorderly, both in relation to neighbouring penetrations and throughout the depth of any particular penetration.

The compressed representation of the visual field observed after day-of-birth lesions of the rostral tectum was considerably more like normal in representation of nasal and temporal visual field than was observed in cases with lesions of caudal tectum. Nevertheless, when asymmetries occurred (three of the seven cases exceeded a 5% difference in representation of nasal visual field versus temporal visual field when compared to normal), nasal visual field was again preferentially represented. In Fig. 1*b*, the rostrocaudal extent of colliculus devoted to the remaining nasal field was 95% of normal; the extent devoted to temporal visual field was 70% of normal. The preferential representation

was never so extreme as that observed after caudal lesions. In no case, however, was there marked compression of the representation of nasal field relative to temporal field, even though the normal tectal terminal area for axons of retinal cells representing nasal visual field had been removed at birth.

An additional deviation from the normal representation of the retina in the tectum was observed in 12 of the 15 animals studied: extreme temporal visual field was represented both at the tectal surface and also deep to the tectal surface, lying directly ventral to receptive fields representing more nasal areas. In some cases, extreme temporal field could be found represented only deep below the tectal surface (Fig. 1*b*, dotted fields). This corresponds to an anatomical pattern observed previously[7–9]; in adult hamsters which had suffered caudal tectal lesions at birth, lesions of the nasal retina elicited axon terminal degeneration in deep superficial gray and in the upper part of intermediate gray in the caudal part of the remaining colliculus. These observations indicate an orderly topographic representation of the retina perpendicular to the surface of the superior colliculus which is never found in normal animals[10,11]. Factors such as inappropriate angles of electrode penetration and reorganisation of collicular lamination, investigated thoroughly, could not account for these results[7–10].

We do not know if the nonlinear compression of the visual field in the hamsters represents the stable end point of a process of compression, or a fixation of the map by maturation before a stable end point has been reached. In either case, the priority of nasal field representation in these compressed maps is an interesting clue to the mechanisms of map formation. The two most likely sources of this priority are features of development: the direction of retinal fibre entrance to the tectum from the rostrolateral quadrant where nasal field is represented, and the sequence of maturation of retinal ganglion cells in hamster retina. We are presently investigating these two possibilities.

A rich VIP nerve supply is characteristic of sphincters

VASOACTIVE INTESTINAL PEPTIDE (VIP), isolated from extracts of porcine duodenum by Said and Mutt[1], was at first thought to be a hormone[2]. Immunohistochemical studies have since revealed that VIP has a neuronal localisation. VIP-containing nerves occur throughout the body, being particularly

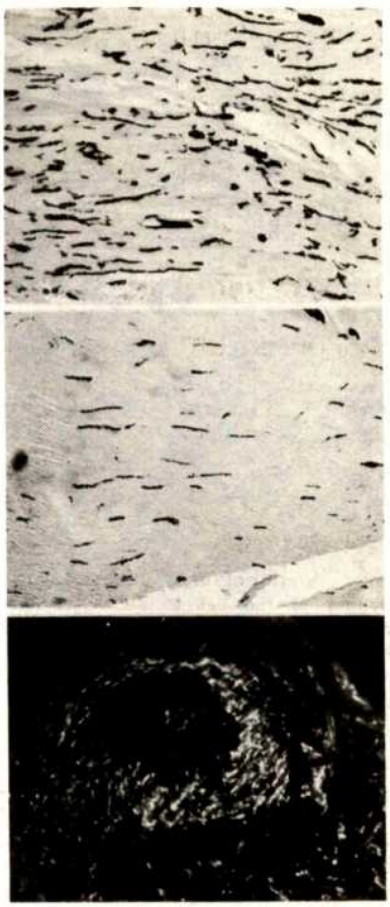

Fig. 1 VIP-immunoreactive nerves (PAP staining) in smooth muscle of the feline pyloric sphincter (top) and duodenum (middle). Note the aggregation of coarse nerves in the sphincter region compared with the much lower number of immunoreactive nerves in the duodenum (×250). Bottom, VIP nerves (immunofluorescence) around the opening of the pancreatic duct in the papilla of Vater (×150).

frequent in the digestive tract[3–7], the genitourinary tract[8–10] and the upper respiratory tract[11]. The nerves storing VIP or other neuropeptides (substance P, somatostatin and enkephalin) apparently represent additional types of autonomic nerves, distinct from the adrenergic and cholinergic ones. A great proportion or the peptidergic nerves seems to originate in nerve cell bodies located close to or within the innervated organ[5–9,11]. The physiological significance of these new types of nerves is a matter of speculation, but a knowledge of their precise anatomical distribution will assist in defining their targets. We have previously observed that structures believed to exert a sphincter function receive a particularly rich supply of such nerves. We have now examined several sphincters, recognised or anticipated, and have established the presence of VIP nerves in all of them.

For chemical analysis specimens were taken from the mid and lower portion of the oesophagus, the stomach (cardia, antrum and pylorus) and the upper duodenum of seven cats of either sex. The material was immediately frozen and stored at −20 °C until extraction in acidified ethanol and analysis by radioimmunoassay[12]. For histochemistry material was collected from the above mentioned locations and from the sphincter of Oddi and the papilla of Vater from three cats. In addition, we collected specimens from the mid and lower portion of the ureter, from the bladder–urethra connection and from the bladder wall. From three male cats specimens were taken from the prostate, urethra and urethral collicles. The specimens were frozen to the temperature of liquid nitrogen in a propane–propylene mixture and freeze-dried. They were then exposed to formaldehyde gas at +80 °C for 1 h (ref. 13) or to diethylpyrocarbonate vapour at

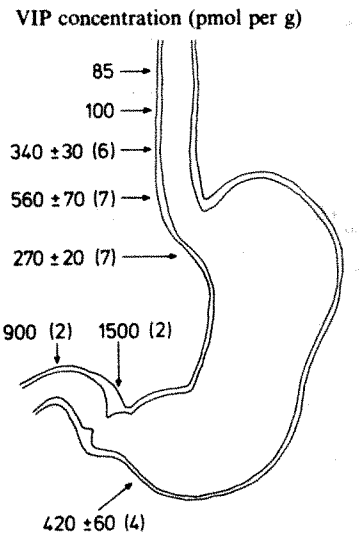

Fig. 2 Schematic drawing of the lower oesophagus, stomach and upper duodenum of the cat to show the distribution of immunoreactive VIP, measured by radioimmunoassay. Single determinations if not otherwise stated. The values for oesophagus and cardia refer to the whole wall, the values for antrum, pyloric sphincter and duodenum refer to smooth muscle only. Mean values ± s.e. (n).

+55 °C for 3 h (ref. 14) and embedded in paraffin. Sections were cut at 5 μm and subjected to the indirect immunofluorescence method[15] of the PAP staining technique of Sternberger[16] for the demonstration of VIP, substance P or Leu-enkephalin. The VIP antiserum (code no. 5603) used in the radioimmunoassay was also used for immunostaining; it has been characterised in detail elsewhere[12,17]. (For details on the use of the VIP, substance P or Leu-enkephalin antisera see refs 4, 18, 19.) The VIP antiserum was used in a dilution of 1:80 (immunofluorescence) or 1:5,120 (PAP staining), the corresponding values for the substance P antiserum dilutions were 1:40 or 1:160 and for the Leu-enkephalin antiserum 1:60 or 1:240. Controls were sections incubated with antiserum inactivated by the addition of excess antigen (pure porcine VIP, synthetic substance P or Leu-enkephalin; 10 μg per ml diluted antiserum). Adrenergic nerves were demonstrated microscopically by fluorescence in the formaldehyde-fixed material[13].

The region of the oesophago-gastric junction, pyloric sphincter, sphincter of Oddi and papilla of Vater received a very dense VIP nerve supply, more so than the smooth muscle of adjacent regions (Fig. 1). Immunochemical assay disclosed much higher VIP concentrations in the lower oesophageal and pyloric sphincter regions than in adjacent regions (Fig. 2). The openings of the ureters and of the urethra into the trigonum area of the bladder received a particularly rich supply of VIP nerves (see also refs 8, 9). By comparison, the body of the bladder and the ureters were sparsely innervated. Also, the smooth muscle surrounding the openings of the vasa deferentia and the prostatic ducts into the urethra were richly supplied with VIP nerves. In addition to VIP nerves the sphincter regions received adrenergic nerves and nerves displaying substance P (see also ref. 18) or enkephalin immunoreactivity. There were many enkephalin nerves in the lower oesophageal sphincter region and in the pyloric sphincter but not more than in adjacent regions; they were very few in the sphincter regions of the genitourinary tract. Acetylcholinesterase-positive nerves are very numerous in the sphincter of Oddi[20], whereas there are few adrenergic nerves in sphincters of the feline gut[21]. Generally, such nerves are not more numerous in sphincter regions than in adjacent regions. Subsequently, we have also found VIP-immunoreactive nerves to be comparatively numerous in sphincters of the guinea pig and rat. On the whole, however, the number of VIP nerves in smooth muscle is lower in these species than in the cat. In the rat immunoreactive-VIP nerves were poorly demonstrated by antiserum 5603, but were easily demonstrated by another VIP antiserum (code no. 98P).

Thus, in the cat a very rich supply of VIP nerves is consistently found in the smooth muscle of all recognised sphincters and in some anticipated sphincters. We propose that a rich local supply of VIP nerves is characteristic of smooth muscle sphincters to the extent that an evaluation of the density of VIP innervation may assist in anatomically defining a sphincter. From what is known of the action of VIP on smooth muscle it seems likely that VIP is involved in sphincter relaxation[22].

This work was supported by the Swedish Research Council (04X-4499). Substance P antiserum was supplied by Dr N. Yanaihara, Leu-enkephalin antiserum by Dr K.-J. Chang (Wellcome), and VIP antiserum no. 98P by Dr S. Said.

Increased sensitivity to (+)amphetamine self-administered by rats following meso-cortico-limbic dopamine neurone destruction

DRUG self-administration (SA) in laboratory animals shows some of the characteristics of intracranial self-stimulation and of other natural reinforcers (for review see ref. 1). Animals will self-administer many of the same drugs abused by human subjects. Recent evidence has shown that (+)amphetamine reinforces behaviour in the same manner as conventional reinforcers[1–3] that it acts mainly on dopamine (DA) transmission, and that locomotor activation and stereotypy are mediated by the mesolimbic–mesocortical (A10 group) and nigro-striatal (A9 group) DA systems, respectively[4,5]. Using various specific noradrenergic and dopaminergic blocking agents in a (+)amphetamine SA retention paradigm, DA transmission blockade was shown to produce effects similar to reward reduction and reward termination[3,6,7]. DA transmission in the frontal-mesolimbic system has been implicated in brain stimulation

Table 1 Effects of (+)amphetamine injections (2 mg per kg, i.p.) on the locomotor activity of sham-operated rats and rats with VMT–A10 lesions

Groups	Locomotor activity (counts)			Time for maximal activation (min)
	1st 10 min	1st h	2nd h	
Control $N=6$	131±24	1,771±225	1,178±177	43±5
VMT–A10 $N=8$	291±38*	1,283±100	496±101*	12.5±1.6*

* The locomotor activity was measured in a circular corridor with photocell beams. The results are presented for each rat as the difference between (+)amphetamine and solvent scores.

reward[8], and the link between self-administration of (+)amphetamine and reward mechanisms, both of which depend on DA transmission, may be related to the craving and early dependence that certain subjects display for addictive drugs. However, the mechanisms which lead to addiction are still unclear, and it is possible that in drug addicts the particularly strong and rapid addicting effect of the drug could be due to a pre-existing imbalance in some homeostatic mechanism. Thus, the use of healthy animals in a steady-state paradigm is not necessarily a good model for the study of the psychological or neurobiological vulnerability to drug addiction acquisition. Because the meso-cortico-limbic DA system may be an essential target for psychostimulant drugs, the lesion of this system could induce disruption of SA behaviour.

We report here that lesions of the ventral mesencephalic tegmentum (VMT) in the area of the meso-cortico-limbic DA cells (A10) induces paradoxically fast acquisition of intravenous self-administration of (+)amphetamine and also greater consumption of this drug.

Of 50 male adult Sprague–Dawley rats anaesthetised with ketamine, 30 received bilateral (±0.4 mm) radiofrequency lesions of the VMT–A10 area surrounding the interpeduncular nucleus and in the remaining 20 rats (controls) the electrode was lowered 1 mm above the VMT area, and no current was passed. One month later, a silastic cannula, filled with a polyvinylpyrollidone solution to prevent blood coagulation in the tubing, was chronically implanted in the jugular vein. The cannula was fixed with a stainless-steel connector on the calvarium. Three days later the SA experiments began. The rats were placed in an operant conditioning chamber with two levers situated at opposite sides of the cage. Depression of one lever activated a syringe pump that delivered 7.5 μg per kg of (+)amphetamine in 2.5 μl in 2 s for each press on a CRF schedule of reinforcement; depression of the other lever resulted in the same noises but led to no infusion. Each session (one every 2 d) lasted 12 h, from 1900 to 0700. The first session served as an operant control, during which the pump was disconnected, and the second and third sessions were the first and second (+)amphetamine sessions, respectively, and in the fourth session the (+)amphetamine was replaced by saline. Each rat was then killed under deep anaesthesia, the brain removed and the lesions examined histologically. Three rats with lesions considered to be unilateral were eliminated from data analysis. The lesions destroyed an area surrounding the interpeduncular nucleus and sometimes reached the medial part of the substantia nigra laterally and the ventral part of the nucleus ruber dorsally. Figure 1 inset shows a typical lesion.

The results are represented in Fig. 2. A two-factor analysis of variance was computed: lesioned against controls (A): $F=53.7$, $P<0.001$; (+)amphetamine against operant-saline (B): $F=49.05$, $P<0.001$; $A\times B$ interaction: $F=17.55$, $P<0.001$. The following remarks can be made. (1) There was no significant difference between the score of the two groups on either the operant or the saline session. (2) In the first (+)amphetamine session, the lesioned group's score was markedly greater than that of the control group ($t=6.1$, $P<0.001$), and different from that of its operant session ($t=10.8$, $P<0.001$). There was a small but significant difference between the control group's score on the first (+)amphetamine session and on their operant session ($t=2.05$, $P<0.05$). (3) The second (+)amphetamine session confirmed the preceding results for the experimental group. The control group's drug session score differed statistically from that of its operant session ($t=3.1$, $P<0.001$). (4) The mean presses on the control lever (for the four respective sessions) were: control group, 8±1, 10±4, 13±5, 9±2; VMT–A10 group, 7.5±1, 18±5, 17±7, 10±3. Typical acquisition and retention scores for a lesioned rat and a control rat are represented in Fig. 1, which shows that lever pressing for (+)amphetamine in the lesioned rat evolved dramatically, with an extreme sensitivity to the drug and enhanced acquisition of the operant response for (+)amphetamine.

The method used here was unusual because it focused on the acquisition of responding, a paradigm which may be particularly good for revealing pre-existing vulnerability to the drug. For this reason, a very small amount of the drug was available for each lever press, permitting only a low blood concentration at the beginning of the session. As the control operant behaviour scores of the two groups were identical, we can conclude that a different brain sensitivity to the drug determined the differing subsequent acquisition time courses. A lowered reactivity to (+)amphetamine in the VMT–A10 group can also be excluded as decreased sensitivity would contradict the rapid acquisition at very low blood concentration. The second clear modification of (+)amphetamine SA induced by VMT lesion is the intake of greater amounts of the drug. This may reflect a pathological need for the drug and a requirement for a higher blood concentration to obtain an identical 'rewarding' effect[3,10,11]. These results must be compared with the relatively low score of the control group for the first (+)amphetamine session. In contrast to the gradual acquisition in control rats, the lesioned group acquired the response in less than 1 h, often less than 30 min and in some cases less than 15 min. Dugthis time the total amount of the drug infused was less than 0.5 mg per kg, allowing us to eliminate motor preservation and stereotypy artefacts often observed in SA experiments[12]. Moreover, although the number of presses on the control lever during the (+)amphetamine session was slightly enhanced, the animals did not show any apparent stereotypy.

The results are paradoxical, as previous data have shown that the blockade of DA release and re-uptake by (+)amphetamine are prerequisites for (+)amphetamine SA[3,6,7]. Consequently, destruction of meso-cortico-limbic DA neurones, suspected to maintain (+)amphetamine reinforced behaviour, should have led to a disappearance of SA acquisition. To clarify this paradox we tested the reactivity and sensitivity to (+)amphetamine after

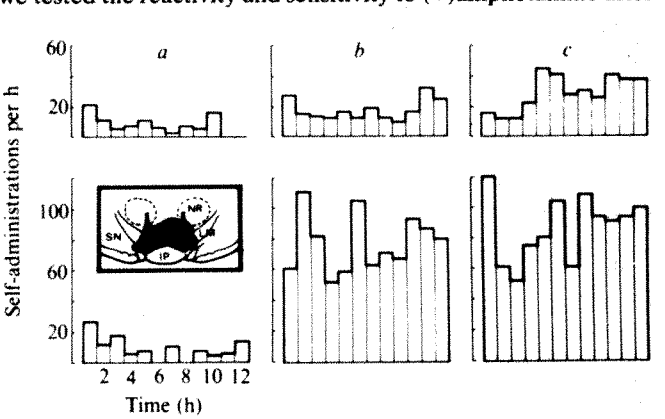

Fig. 1 Typical self-administration behaviour (0.75 mg per kg (+)amphetamine per 100 administrations) of a control rat (rat 5314, upper histograms) and a rat with bilateral VMT–A10 lesions (rat 5340, lower histograms). The lesioned area represented is typical of the lesions of the experimental group (IP, interpeduncular nucleus; SN, substantia nigra; NR, nucleus ruber; LM, lemiscus medianus). *a*, Operant session; *b*, first (+)amphetamine session; *c*, second (+)amphetamine session.

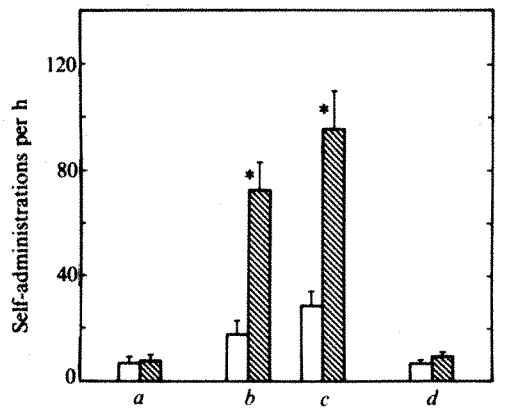

Fig. 2 (+)Amphetamine self-administration (0.75 mg per kg (+)amphetamine per 100 administrations) in rats after radiofrequency lesions of the dopaminergic meso-cortico-limbic (A10) cell group lying in the ventral mesencephalic tegmentum (VMT) surrounding the interpeduncular nucleus (lesioned against controls: * $P < 0.001$, Student's t-test). *a*, Operant session; *b*, first (+)amphetamine session; *c*, second (+)amphetamine session; *d*, saline. □, Controls; $n = 20$; ▨ VMT–A10 lesioned; $n = 27$.

VMT–A10 lesioning. Eight VMT–A10-lesioned and six sham-operated rats, with no experience of the drug, received 2 mg per kg (+)amphetamine intraperitoneally (i.p.), and behavioural activation was measured in a circular corridor. Table 1 indicates that the lesion induced a 'hyper-reactivity' to (+)amphetamine, observed immediately after the injection. The maximal effect of the drug occurred at 12.5 min and 43 min, respectively, in the lesioned and control groups. However, it is also clear that the lesioned rats were 'hyposensitive' to the drug as the behavioural activation was observed for only 1 h in the lesioned group but lasted more than 2 h in the control group.

This second experiment may explain the SA behaviour of VMT–A10-lesioned animals. The hyper-reactive phase to (+)amphetamine could explain the rapid acquisition of SA, and the decreased time course could account for the high response rate (to maintain the rewarding effects of the drug). Our results clearly indicate that (+)amphetamine-induced behavioural activation is not completely blocked by our radiofrequency lesion of the VMT–A10 area, in contrast to the blockade obtained after massive destruction of DA–A10 terminals induced by 6-hydroxydopamine (6-OHDA) administration[13]. Therefore, it is probable that some DA neurones involved in (+)amphetamine-induced behavioural activation are still intact, that they are hyperactive, and that they react more strongly to (+)amphetamine but for a much shorter time. This hypothesis could explain the discrepancy between our results and previous data, which have shown that SA of psychostimulant drugs such as (+)amphetamine and cocaine are dependent on DA mechanisms; in these studies SA is suppressed by blockade of DA activity either by injecting a specific DA-receptor blocker[3,6,7] or by total 6-OHDA destruction of DA-A10 innervation[14]. The hypothesis of incomplete destruction of DA neurones to explain (+)amphetamine SA effects could also explain the discrepancy between the behavioural syndrome induced by destruction of DA–A10 neurones after 6-OHDA injection into the terminal areas[5,13] and the syndrome induced by lesion of the DA cell bodies. Radiofrequency lesion or local infusion of small amounts of 6-OHDA into the VMT–A10 area elicit a permanent behavioural perturbation characterised by locomotor hyperactivity and disruption of complex behaviour[9,15–17]. This syndrome is correlated with depletion of DA but not of serotonin or noradrenaline[18], and it may be due to a pathological state produced by incomplete destruction of VMT–DA neurones and overactivity of the remaining DA neurones. The syndrome is antagonised by chronic (+)amphetamine treatment or by very low acute doses of apomorphine[19]. These drugs shift the activity of the lesioned rats towards lower, normal levels. The possible existence of DA receptors supersensitivity involved in reward mechanisms could explain the increased nucleus accumbens self-stimulation scores induced by radiofrequency lesion of the VMT area[20], while other studies using different lesion techniques demonstrated a decrease of this behaviour[21]. Our results may thus help in understanding the psychopathological disturbance which leads to drug addiction.

Extracellular Ca^{2+} and excitation–contraction coupling

THE role of external Ca^{2+} in excitation–contraction coupling has been controversial since Sandow[1] put forward the idea that contraction is initiated by an influx of Ca^{2+} on depolarisation. In the very thin lamellae (1 μm) of *Branchiostoma* myotome muscle 'Ca^{2+}-free' solutions with 1 mM EGTA block twitches completely[2,3]. It was concluded that the Ca^{2+} influx during the action potential directly activates the myofilaments[2]. In frog muscle twitches remain unchanged in 1 mM $EGTA^{2-}$ (refs 4, 5). To ensure that $[Ca^{2+}]$ is sufficiently reduced in the narrow transverse tubular (T) system Barrett and Barrett[6] raised the Ca^{2+} buffer concentration to 80 mM and observed that action potentials were no longer followed by twitches. In this letter we demonstrate that some further changes in the composition of the external fluids result in the restoration of contractions in both *Branchiostoma* and frog muscle indicating that a Ca^{2+} influx is not necessary for the initiation of contraction.

Single muscle fibres from the M. semitendinosus of the frog (*Rana temporaria*) were transferred into a Perspex chamber[7] which allowed a quick exchange of solutions. Isometric contraction was measured with a force transducer[5]. To prevent a decrease in resting potential[5,6] and an increase in external surface charge density[8] at high EGTA concentrations, the solution included 5 mM free Mg^{2+}. The increase in ionic strength and osmolarity had no appreciable effect on the fibres. Figure 1 shows that in 80 mM free EGTA ($[Ca^{2+}] < 10^{-10}$ M) twitch

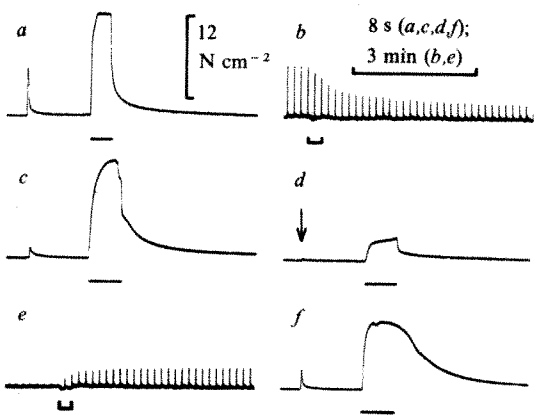
0028–0836/79/280158—03$01.00

© Macmillan Journals Ltd 1979

height decreased to 30% after 2 min. It then declined more slowly, reaching 5% after 2 h. Addition of 15 mM NaSCN caused a considerable recovery up to 30% of the initial level. The early fall in twitch force is probably due to an accelerated onset of inactivation, as in similar conditions the reduction in free Ca by as little as 2.5 mM $EGTA^{2-}$, in the presence of Mg^{2+}, causes a shift of the steady-state inactivation curve by 20–30 mV towards more negative potentials[5]. Our present finding that twitches did not disappear completely after a few minutes[6] might be due to the presence of Mg^{2+}, which prevents an increase in external surface charge density and thus a further shift of the inactivation curve beyond the resting potential. The continuous slow decrease in twitch force to very low values after the early fall might then be explained by assuming that (1) the final concentration of $EGTA^{2-}$ in some part of the T-system is reached very slowly, (2) a continuous loss of Ca^{2+} from the muscle cell causes a depletion of internal Ca-stores, or (3) $EGTA^{2-}$ has deleterious effects on the T-system.

However, the assumption that $[Ca^{2+}]$ in the T-system decreases only very slowly below the myoplasmic Ca^{2+} concentration[11] ($\sim 10^{-7}$ M) is very unlikely considering the SCN^- effect. This anion, which should not alter tubular free [Ca], causes a remarkable recovery of the twitch amplitude. It is known to shift the activation threshold to more negative potentials[12] without causing a corresponding shift in inactivation (our unpublished observations). This strongly suggests that a passive influx of Ca^{2+} during membrane depolarisation is not a prerequisite for activation.

The possibility that loss of internal Ca^{2+} and/or secondary effects are mainly responsible for the slow decline in force under high EGTA is also unlikely, as shown by the nearly complete recovery from $EGTA^{2-}$ application and from the tetanus results. In the experiment shown in Fig. 1 tetanus force fell to 95% and 23% after 40 and 120 min, respectively, but rose again to 68% in SCN^-. The tetanus/twitch ratio increased from 2 : 1 in normal conditions to about 10 : 1 in high EGTA. In one of the 11 experiments it reached 55 : 1. The increase in tetanus/twitch ratio shows that the coupling efficiency improves during repetitive activity, probably by a 'normalisation' of the inactivation kinetics[5]. In this context it should be noted that the coupling process improves, although internal $[Ca^{2+}]$ and thus the outwardly directed driving force for calcium ions increases. Thus it is likely that a further acceleration of inactivation is mainly responsible for the slow decline in twitch force in high EGTA.



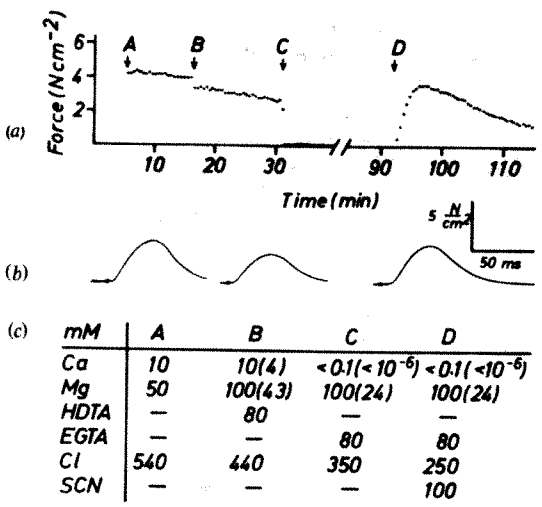


Fig. 1 Effect of high EGTA and SCN^- on twitches and tetani (50 Hz; indicated by horizontal bars) of an isolated skeletal muscle fibre (diameter 130 μm). *a*, Ringer solution with 1.8 mM Ca^{2+}; *b*, change from modified Ringer (see below) to a solution with 80 mM free EGTA ($[Ca^{2+}] \leq 10^{-10}$ M) and 5 mM free Mg (96.2 mM total EGTA and 21.2 mM total Mg). The free concentrations were calculated as described by Portzehl, Caldwell and Rüegg[9] using the absolute binding constants given by Sillén and Martell[10] and assuming a Ca^{2+} contamination of 10^{-2} mM. *c* and *d*, Twitches and tetani after 40 and 120 min in high EGTA, respectively. *e*, Change from high EGTA to high EGTA plus 15 mM SCN^-, *f*, after 6 min in the latter solution. The brackets show the time needed for the exchange of solutions. In order to avoid a transient depolarisation beyond the contraction threshold after the replacement of NaCl in Ringer by Na–EGTA we exchanged 50 mM NaCl of Ringer by 50 mM Na propionate 10 min before application of $EGTA^{2-}$. All solutions contained 2.5 mM KCl and 5 mM $MOPS^-$ as buffer, $pH = 7.0$, $T = 22$–23 °C.

(c)

mM	A	B	C	D
Ca	10	10(4)	$<0.1(<10^{-6})$	$<0.1(<10^{-6})$
Mg	50	100(43)	100(24)	100(24)
HDTA	—	80	—	—
EGTA	—	—	80	80
Cl	540	440	350	250
SCN	—	—	—	100

Fig. 2 Effect of high EGTA and SCN^- on twitch amplitude of a myotome strip from *Branchiostoma*. Diameter 170 μm. Stimulating frequency 2 per min. *a*, Twitch amplitude in different solutions. *b*, Time course of single twitches. *c*, Composition of solutions in order of application (mM) with free concentrations of Ca and Mg in brackets. All solutions contained in addition (in mM): Na^+ 400, K^+ 10 and Tris (as buffer) 10, $pH = 8.0$; $T = 10$ °C. Since 80 mM EGTA replaces a considerable amount of Cl^-, HDTA (hexamethylenediamine*N,N,N',N'*-tetra-acetic acid) was added before application of EGTA to moderate the depolarising action of Cl^- reduction. This substance has a comparable binding characteristics for Mg^{2+} but possesses a 10^6 times smaller absolute binding constant for Ca^{2+} than EGTA. Because very low concentrations of free Mg led to spontaneous twitches and contractures in Ca^{2+}-free solutions a drastic reduction in free Mg was prevented in sol. *B–D* by increasing the total concentration to 100 mM. A large part of Mg^{2+} was reversibly bound to EGTA, thus reducing free EGTA but not its capacity to buffer $[Ca^{2+}]$ below 10^{-9} M.

For experiments with myotomes of *Branchiostoma lanceolatum* muscle strips, 1.5 mm long and 0.1–0.4 mm thick, were dissected and isometric twitches were elicited by short supramaximal current pulses. Figure 2 shows twitch amplitude in solutions of different composition. The pretreatment with HDTA (see legend to Fig. 2) caused a small decrease in twitch height, which might be due to the concurrent decrease in free calcium. When, however, external $[Ca^{2+}]$ was drastically reduced by high EGTA (solution *C*) twitch amplitude fell to very low values within 1 min. After 1 h, when twitches were no longer visible, 100 mM Cl^- was replaced by SCN^- (solution *D*). Subsequently twitch height increased almost to the original value within a few minutes. Thereafter, force gradually declined again, reaching 1/3 after 30 min.

Apart from a prolongation in latency time by about 100%, the time course of twitches in $EGTA^{2-} + SCN^-$ was very similar to the control twitches (Fig. 2*b*). This again suggests that SCN^- simply strengthens the natural coupling process.

In our experiments we used 80 mM $EGTA^{2-}$ to reduce the concentration of free Ca^{2+} below 10^{-10} M. Even if we assume that the actual Ca^{2+} concentration in the T-system or extracellular clefts remains 2–3 orders of magnitude higher than in the bulk solution it still should be below that measured in normal conditions in the myoplasm. In agreement with recent conclusions drawn from experiments with the calcium indicator dye arsenazo III[13] we therefore believe that an influx of Ca^{2+} is not a prerequisite for the activation of contraction. Models[14] which directly combine the Ca^{2+} release from the sarcoplasmic

reticulum with the membrane potential of the T-tubular membrane seem more appropriate to explain excitation–contraction coupling.

We thank Drs D. Miller and G. Stephenson for helpful discussions. This work was supported by Deutsche Forschungsgemeinschaft (SFB 114 'Bionach').

Parallel regulation of acetylcholinesterase and pseudocholinesterase in normal, denervated and dystrophic chicken skeletal muscle

IN vertebrate skeletal muscle acetylcholinesterase (AChE, EC 3.1.1.7) is usually considered to be involved in the termination of impulse transmission by hydrolysis of acetylcholine[1]. AChE is often accompanied by a second enzyme[2], pseudocholinesterase (ψChE, EC 3.1.1.8), which differs from AChE in substrate specificity and in susceptibility to anticholinesterases[3,4]. No role comparable with that of AChE in synaptic transmission is known for ψChE, despite its abundance at some sites and its occurrence (as shown histochemically) with AChE in various muscle endplates[1,5]. It has been suggested that ψChE is a precursor of AChE in the superior cervical ganglion[6,7]. Moreover, in ganglia and skeletal muscle of rats, forms of ψChE have been demonstrated[8] homologous with forms of AChE observed previously[9–11]. Elevated levels of AChE have been demonstrated in aqueous extracts of fast-twitch muscles of dystrophic as compared with normal chickens[12,13]; ψChE levels increased similarly[13], and also in such extracts of denervated muscles of normal chickens[14]. We show here that the total amounts and forms of AChE change in parallel with those of ψChE during development of skeletal muscles of both normal and dystrophic chickens, as well as on denervation of normal muscle. Our data strongly indicate that in these tissues the two enzymes are controlled by a common regulatory mechanism.

It has been reported[12,15] that embryonic chick muscle has high AChE concentrations which fall during maturation, but those studies used conditions of no or low salt or detergent, which are now known[8,11,16,17] to give low AChE extraction. We have homogenised the tissues in 1% Triton X-100/1 M NaCl, shown[17] to extract 95–100% of the total muscle AChE, and find (Table 1) that in the pectoral muscle of normal chickens AChE

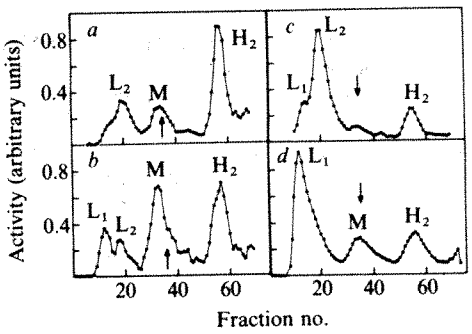

Fig. 1 Sucrose gradient centrifugation profiles of AChE and ψChE activity in extracts of pectoral muscle of normal (line 412) and dystrophic (line 413) chickens. *a*, AChE in muscle of a normal 19-d embryo; *b*, ψChE in muscle of a normal 19-d embryo; *c*, AChE in muscle from a 32-d dystrophic chicken; *d*, ψChE in muscle from a 32-d dystrophic chicken. Centrifugation was carried out on 5–20% sucrose gradients as described previously[19], using extracts obtained as described in Table 1. AChE was assayed using 0.75 mM acetylthiocholine after 30 min preincubation with 10^{-4} M *iso*OMPA. ψChE was assayed using 0.75 mM butyrylthiocholine in the presence of 10^{-5} M BW 284C51. The arrow denotes the position of a catalase marker, taken as having sedimentation coefficient 11.4S.

levels are strikingly reduced in 1-month-old, as opposed to embryonic birds, and ψChE levels follow a similar course. In dystrophic birds, an initial decrease in AChE levels in pectoral muscle is soon followed by a dramatic increase with onset of the disease, and again the ψChE levels increase in parallel. Also, in the slow tonic anterior latissimus dorsi (ALD) muscle, which is not affected by dystrophy, significant (and similar) amounts of ψChE occur with AChE in both normal and dystrophic muscle. Table 1 also shows that following denervation of another fast-twitch muscle, the posterior latissimus dorsi (PLD), a 30-fold elevation in AChE levels occurs in 3-week-old birds, accompanied by a >20-fold elevation in ψChE levels.

Sucrose gradient centrifugation of extracts of chicken skeletal muscle reveals[18,19] several molecular forms of AChE which are principally concentrated in three zones of the gradient, arbitrarily designated as heavy (H, 16–20S), medium (M, 10–13S) and light (L, 4–7S). It has recently been demonstrated that the H_2 form (~20S) predominates in normal adult pectoral and PLD muscles[17,19], that the L_2 (~6.5S) form is greatly elevated in dystrophic fast-twitch muscle[17,19–21], and that in young or embryonic pectoral muscle increased levels of M (~11S) and H_1 (~16S), as well as L forms are observed[17,19]. Figure 1*a* shows a typical sucrose gradient profile for AChE obtained with an extract of embryonic muscle, displaying the L_2, M and H_2 forms as the dominant components. Figure 1*b* shows a profile for ψChE in the same tissue extract. Activity peaks of ψChE are observed in the H, L and M regions of the gradient, as for AChE. The principal difference is that a considerable part of the activity in the L region corresponds to an L_1 (~4S) component. In the case of AChE the L_1 form is seen in large amounts only when protease inhibitors (always used here; see Table 1) are omitted from the extraction medium[19]. L_1 AChE thus seems to be produced by proteolytic degradation of L_2, which is apparently a dimer of L_1 (ref. 22). Figure 1*c* shows that in adult dystrophic pectoral muscle the L_2 component of AChE is considerably larger than the H_2 component, with the M species making only a minor contribution. As shown in Fig. 1*d*, in the dystrophic adult muscle ψChE activity is also present in all three regions of the gradient. Again, the light forms are elevated, with the L_1 form predominating, but the M and H_2 forms are also prominent. The ψChE activity in the gradients displayed in Fig. 1*b*, *d* was assayed using butyrylthiocholine in the presence of the selective AChE inhibitor[4], BW 284C51. When butyrylthiocholine and BW 284C51 were supplemented with the selective ψChE inhibitor[4], tetra-*iso*-propyl pyrophosphoramide (*iso*OMPA), no activity was observed in any part of the gradient. This clearly establishes that all peaks observed represent ψChE. It should also be noted that each ψChE peak seems to be fractionally

0028-0836/79/280160—03$01.00

© Macmillan Journals Ltd 1979

lighter (by 0.5–1S) than its corresponding AChE form. Thus, L_1, L_2, M and H_2 for ψChE have on average $s_{20,w}$ = 4.0, 5.9, 10.5 and 19.1 S, respectively.

The content of ψChE in the fast-twitch muscles of normal chickens is very low at 28 d of age (Table 1) and later. Nevertheless, this enzyme was shown (ref. 17 and additional unpublished data) to be a real component of both fast-twitch and slow tonic muscles of mature normal chickens, by the use of prolonged enzymatic reaction incubations of similar sucrose gradients: their pectoral and PLD muscles (at 32–100 d, perfused to remove blood ψChE) showed significant L ψChE (mainly L_2) and less, but distinct, M and H ψChE. In their ALD muscles, L_1 and L_2 are higher, with some M (and a trace of H) ψChE also present; the pattern is as shown[19] for AChE there. On maturation of normal fast-twitch muscle, therefore, the parallel control of ψChE and AChE forms is lost, but it remains in the mature slow tonic muscle.

Vigny *et al.*[8] reported only minute amounts of an H form of ψChE in rat supercervical ganglia and could not demonstrate any H form in mature skeletal muscle. It is thus particularly interesting that, using embryonic or dystrophic birds, we can demonstrate considerable ψChE activity in the H region, as the H forms of AChE are those which are ascribed to the endplate region in skeletal muscle[9,10,18]. Consistent with this occurrence of the H forms of AChE at the endplate region is their appearance on innervation and their loss on denervation[18,21]. It was, therefore, important to see whether the H form of ψChE would also disappear on denervation. This was investigated in the tonic ALD muscle of very young (~7-d) chickens, where the H forms of both AChE and ψChE are quite prominent (Fig. 2*a*, *c*). We confirmed that the H_2 form of AChE is largely eliminated within 7 days, with a concomitant increase in amounts of the lighter forms of the enzyme (Fig. 2*b*). The H_2 form of ψChE is similarly reduced (Fig. 2*d*), and, as in the case of AChE, increased amounts of the lighter forms of the enzyme are observed. A similar denervation experiment (not shown) on the PLD muscle of a mature dystrophic bird also demonstrated disappearance of the prominent H peak of ψChE together with disappearance of the corresponding AChE peak.

The role of the motor nerve in controlling muscle differentiation is especially pertinent to attempts to understand whether a given myopathy is of neurogenic or myogenic origin. In the case of inherited muscular dystrophy in humans, as well as in chickens and other experimental animals, this issue is extremely controversial[23]. Although AChE levels increase in chicken dystrophic muscle as in normal denervated muscle, this does not imply that the control of AChE levels is strictly neurogenic, as ACh receptor levels increase after denervation but not during dystrophy[24], and limb-bud transplant evidence has suggested that dystrophy in chickens is of myogenic origin[25]. Moreover, whereas after denervation the H_2 form of AChE is virtually eliminated (see Fig. 2 and refs 18, 21), in the dystrophic condition it is elevated[17,19–21]. Whatever the primary lesion in the dystrophy, our data show that it affects the levels and forms of ψChE similarly to those of AChE.

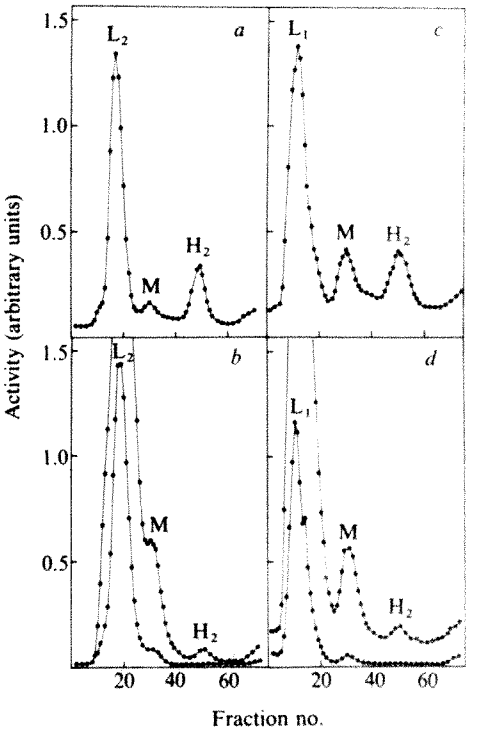

Fig. 2 Sucrose gradient profiles of AChE and ψChE activity in extracts of innervated and denervated anterior latissimus dorsi (ALD) muscles. Leghorn chickens were denervated on day 1 post-hatch as described in Table 1, and killed on day 7 together with control birds. *a*, AChE in control bird; *b*, AChE in denervated bird; *c*, ψChE in control bird; *d*, ψChE in denervated bird. Extracts were made as in Table 1, gradients were run as in Fig. 1 and assays carried out as in Fig. 1 except that BW 284C51 was omitted in the assay of ψChE. In the case of denervated muscle (*b*, *d*) the upper profile, in each case, was obtained by developing the gradient for the same time as for the corresponding control muscle (*a*, *c* respectively); the lower profile represents incubation for a much shorter time so as to reveal the relative magnitudes of the L peaks.

Table 1 Amounts of acetylcholinesterase and pseudocholinesterase in extracts of fast-twitch muscle from normal, denervated and dystrophic chickens

Muscle	Normal AChE	Normal ψChE	Normal, denervated AChE	Normal, denervated ψChE	Dystrophic AChE	Dystrophic ψChE
Pectoral, 19 d *in ovo*	8.4	0.7			5.8	0.6
Pectoral, 32 d post-hatch	0.15	<0.01			1.9	0.6
PLD, 28 d post-hatch	0.88	<0.01	26	0.24		
ALD, 32 d post-hatch	3.90	0.27			2.26	0.20

Pectoral and ALD muscle samples were dissected from freshly killed embryos or 32-d-old chickens (normal [line 412] or dystrophic [line 413] from the University of California flock). Posterior latissimus dorsi (PLD) muscles were dissected from freshly killed normal Leghorn chickens. Denervation was carried out 7 d before sectioning the main nerve trunk at the brachial plexus. Tissue extracts were prepared as described previously[19], in a medium containing protease inhibitors which had the following composition: 5 mM *N*-ethylmaleimide, 2 mM benzamidine, 10 mM EGTA, 20 μg ml^{-1} pepstatin, 40 μg ml^{-1} leupeptin, 1 mg ml^{-1} bacitracin, 1% Triton X-100, 1 M NaCl, 0.01 M phosphate, *p*H 7.0. AChE was assayed on 0.75 mM acetylthiocholine as described previously[19], after preincubation with 0.1 mM *iso*OMPA for 40 min to permit full inactivation of ψChE[4]. ψChE was assayed using either 0.75 mM acetylthiocholine in the presence of 5×10^{-5} M BW 284C51 (pectoral and ALD) or 0.75 mM butyrylthiocholine (PLD). The figures shown represent units per g tissue, where 1 unit is the amount of enzyme hydrolysing 1 μmol of substrate per min in the assay conditions used.

Because AChE and ψChE show large differences in binding properties[3,4], and no immunological cross-reactivity[8], we presume they are products of different genes. For human serum ψChE a separate locus has, in fact, been established by analysis of genetic variants, including an inherited deletion of only this enzyme[26]. Consistent with the concept of separate genes for muscle AChE and ψChE, the two enzymes do not always vary in parallel (in maturation of normal fast-twitch muscle). Thus, the present finding, that in several different states their various forms do change in parallel, is best explained by a regulatory mechanism that is common to the two genes. The close homology of the molecular forms of AChE and ψChE suggests that they are assembled into functional species by a similar mechanism. This is particularly remarkable in the case of the H form, where current evidence with respect to AChE supports the concept of a complex structure in which the catalytic subunits are attached to a collagenous tail[16,22,27] which anchors the enzyme to the basal lamina[28].

This study was supported by the Muscular Dystrophy Association of America (MDA), the Muscular Dystrophy Group of Great Britain and INSERM (France). I.S. held a Senior Fellowship of the MDA. The chicken colony is maintained by the W. and JB. Eastwood Muscular Dystrophy Research Facility,

directed by Dr P. J. Barnard, whom we thank for advice. We thank Mr David Green for assistance, and the US-Japan Cooperative Program for leupeptin and pepstatin.

Human embryonic haemoglobins Gower 1 and Gower 2

THE human embryonic haemoglobins (Hbs) Gower 1 and Gower 2 (ref. 1) are present in fetuses up to 60 mm crown–rump measurement[2]. However, relatively little is known about the structure and function of these haemoglobins because of the difficulty in obtaining suitable material, particularly since the introduction of the suction method for terminating pregnancy in the first trimester. Here we present the amino acid composition and sequence data for the human ε-chain, prepared by purifying Hb-Gower 2 ($\alpha_2\varepsilon_2$) from early abortion samples. In addition, separation of embryonic red cells from the majority of the maternal red cells has led to the isolation of Hb-Gower 1 and the demonstration that it has the composition $\zeta_2\varepsilon_2$.

Material was collected from vacuum abortions of 6–10 weeks gestation carried out by the standard technique for unrelated indications. The sample was initially passed through a coarse sieve to remove any tissue fragments, and then through a 20-μm pore-size filter. The red cells were packed and washed three times with isotonic saline, then lysed with water and the membranes extracted with carbon tetrachloride. These haemolysates contained only small amounts of Hb-F, and Hb-Gower 1 or Hb-Gower 2 were detected in only a few samples by starch gel electrophoresis.

The first step in the purification was the removal of Hb-A using a modification of the chromatographic method described by Huisman and Dozy[3]. The haemolysates were equilibrated against 0.05 M Tris-HCl, *p*H 8.05 ± 0.05, and loaded at room temperature on to a DEAE-Sephadex column (3 × 30 cm) equilibrated against the same buffer. The haemoglobins were eluted with *p*H 8.05 buffer and the first haem-containing peak collected; this included Hb-Gower 2, Hb-A_2, small amounts of Hb-A and some carbonic anhydrase. This fraction was concentrated and dialysed against developer A consisting of 0.2 M glycine and 0.01 g dl^{-1} potassium cyanide, *p*H 7.4–7.7, and loaded at room temperature on to a column (1.5 × 25 cm) of microgranular DEAE-cellulose DE52 equilibrated with developer A (ref. 4). Hb-Gower 2 was eluted using developer A only, all other haemoglobins remaining firmly attached to the cellulose in these conditions. The Hb-Gower 2 was checked for purity by measuring the *A* ratio 280/345 nm of each fraction, and only those uncontaminated (ratio <1.5) with non-haem proteins were concentrated and used.

The electrophoretic mobility of Hb-Gower 2 was similar to that described previously[1]. Spectral analysis between 250 and 700 nm of the oxygenated purified Hb-Gower 2 showed only minor differences when compared with a solution of oxyHb-A. Sephadex G-100 gel filtration[5] gave a value of 30,000 for the molecular weight of Hb-Gower 2 and 45,000 for Hb-A, presumably indicating that the tetramer dissociates into $\alpha\varepsilon$ dimers more readily than does Hb-A in similar conditions. SDS-polyacrylamide gel electrophoresis of Hb-Gower 2 in a concentration gradient of acrylamide[6] that just resolved α- from β-chains, gave a broad band, the fastest portion corresponding to the α-chains of Hb-A with an overlapping zone between the α- and β-chains. There was no electrophoretic resolution of the α- from the ε-chains after treatment of the protein with *p*-chloromercuribenzoate (PCMB)[7]. Attempts to separate the globin chains using chromatography on CM-cellulose in 8 M urea[8] yielded a single protein peak consisting solely of α-chains; the ε-chains could not be eluted from the column even using much stronger buffers and a higher *p*H. Separation of the globin chains was achieved by electrophoresis on cellulose acetate in 6 M urea, *p*H 6.4 (ref. 9), the ε-chains migrating anodally, close to the α-chains. However, this method was not suitable for preparative purposes. Further analysis was therefore carried out on whole globin prepared from purified Hb-Gower 2 by acid/acetone precipitation.

Tryptic peptide maps prepared by standard techniques[8] showed many ninhydrin-positive spots immediately recognisable as peptides from the α-chain, but at least 10 were thought to be peptides from the ε-chain; all peptides were eluted with 6 M HCl for amino acid analysis. From the data obtained it was concluded that the ε-chain is similar to both the β- and γ-chains, and using tables from Dayhoff[10] a sequence of the first 10 tryptic peptides (residues 1–87) of the ε-chain was constructed by comparison with known mammalian β-chain sequences. Six milligrammes of Gower 2 globin were also analysed in a Beckman model 890C protein sequencer. The data confirmed the sequence of the first 40 residues (Fig. 1).

Throughout these procedures no peptides belonging to the second half of the ε-chain were demonstrated. Presumably, these had precipitated as an insoluble core of undigested globin which was not detected in the small amount of material used. Cyanogen bromide digestion of Gower 2 globin followed by tryptic digestion and peptide mapping of the fragments separated by Sephadex chromatography showed the characteristic C-terminal peptide of β- and γ-chains: Tyr-His. There were other peptides which had compositions resembling known peptides from the C-terminal halves of the β- and γ-chains, and

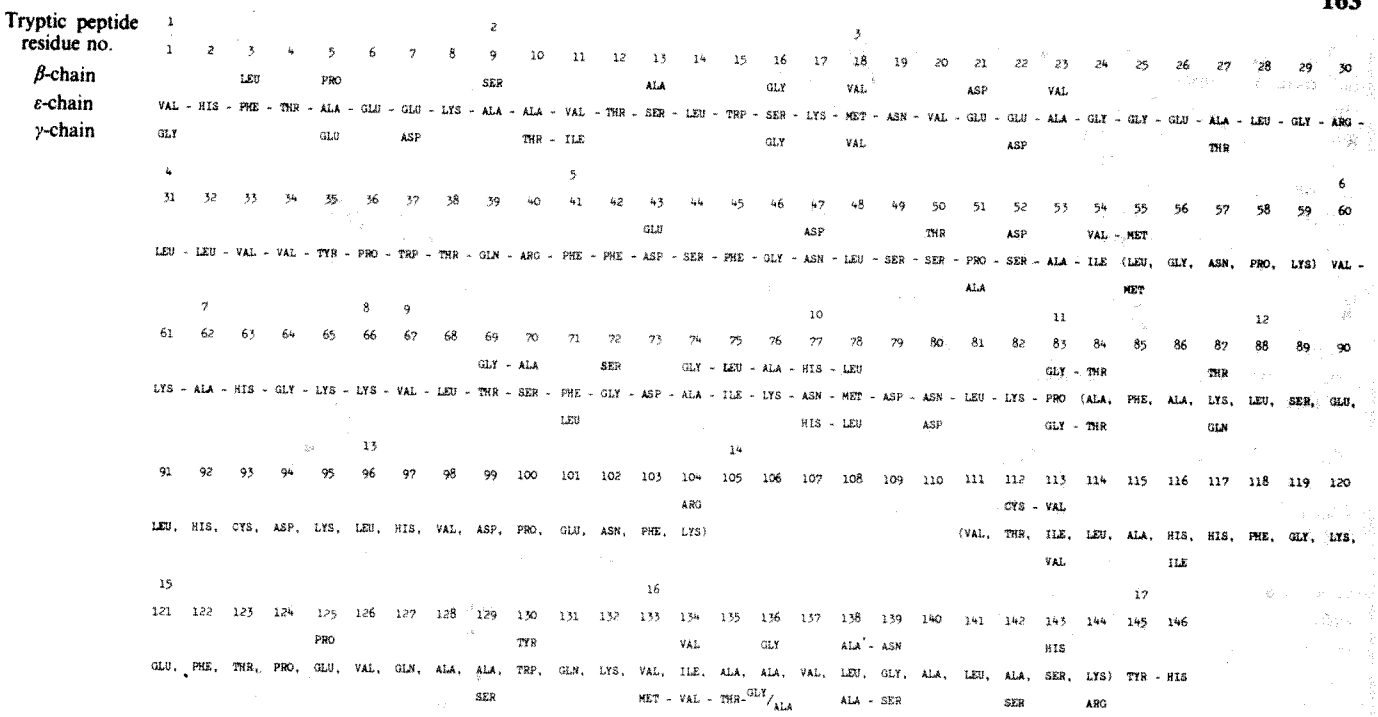

Fig. 1 Amino acid sequence of the human embryonic ε-chain. Residues 1–54, 60–83 and 145–146 are determined sequence, residues 55–59, 84–104 and 111–144 are a tentative sequence constructed by homology with known mammalian β-chains. Only differences in the human β- and γ-chains have been included.

from these a tentative sequence for the second half of the ε-chain was constructed. In addition, manual and automatic sequencing of one of the cyanogen bromide fragments and some tryptic peptides derived from it enabled a sequence for residues 41–83 to be established (Fig. 1). All the sequence data corresponded entirely to the amino acid compositions of peptides previously determined. The assignment of amide residues where sequence is not available was made using amino acid composition and electrophoretic mobility of the peptides, as well as homology with other β-like chains.

The sequence of the ε-chain established so far shows that it differs from both the β- and γ-chains. Using the definitive sequence information in Fig. 1 there are 24 differences between the ε- and β-chains and 18 between ε- and γ-chains, compared with 26 differences between β- and γ-chains. Tryptic peptides 4, 6, 7, 8, 11 and 17 maintain the invariant composition found in their equivalents in the human β-, γ- and δ-chains. Further, the ε-chain contains four isoleucine residues whereas there are none in the β-chain and three in the γ-chain. There is no cysteine at position 112, explaining the inability to separate the α- from the ε-chains after PCMB treatment. The difference in charged amino acids so far established is consistent with the differences in electrophoretic mobility between Hb-Gower 2 and Hb-A or Hb-F.

Hb-Gower 1 could not be isolated using the procedure described above, presumably because it was either not separated from Hb-A or precipitated during the purification. Therefore, as a preliminary step in the isolation of Hb-Gower 1, maternal red cells were separated from the embryonic cells. Although the latter are conspicuously large (~15–20 μm mean cell diameter) and retain their nucleus in a condensed form, they constitute less than 0.01% of the total red cells collected from an abortion sample. Separation of the two cell types was achieved using a large-scale Ørskov–Jacobs–Stewart reaction[11] which is based on the low levels of carbonic anhydrase present in fetal cells. The cells were incubated initially for 2 min with acetazolamide and NH_4HCO_3. Because of the large volumes necessary for the preparation, the mixture was then centrifuged for 5 min at 2,000*g* at 4 °C to sediment unlysed cells. The latter were resuspended in isotonic saline and spun through Ficoll[11]. Placental cells and leukocytes were removed by centrifuging the suspension through first 40% and then 60% Percoll at 2,000*g* at 4 °C for 5 min. With sufficiently early embryonic samples a preparation containing 100% large nucleated red blood cells could be obtained.

The embryonic red cells were lysed with water and the membranes pelleted by spinning at 18,000*g* for 15 min. No organic solvents were used as this denatures the haemoglobin. The haemolysates were dialysed against developer A and loaded on to a DEAE-cellulose DE52 column as described previously. After elution of Hb-Gower 2 with developer A a salt gradient was applied by mixing 150 ml developer A containing 0.005 M NaCl in a constant-volume chamber with developer A containing 0.03 M NaCl. Tryptic peptide maps of one haemoglobin fraction which migrated electrophoretically close to Hb-A_2 showed peptides which were characteristic of the ε-chain. Of the peptides in Fig. 1, 1, 3, 4, 5, 6, 7, 7–8 and 9 were identified and confirmed by amino acid analyses. Other ninhydrin-positive spots were clearly peptides from the ζ-chain[12], with identical compositions for residues 17–31 (ζ4), 32–40 (ζ5), 57–61 (ζ7–8), 90–92 (ζ10), 93–99 (ζ11) and the C-terminal peptide, residues 140–141 (ζ14).

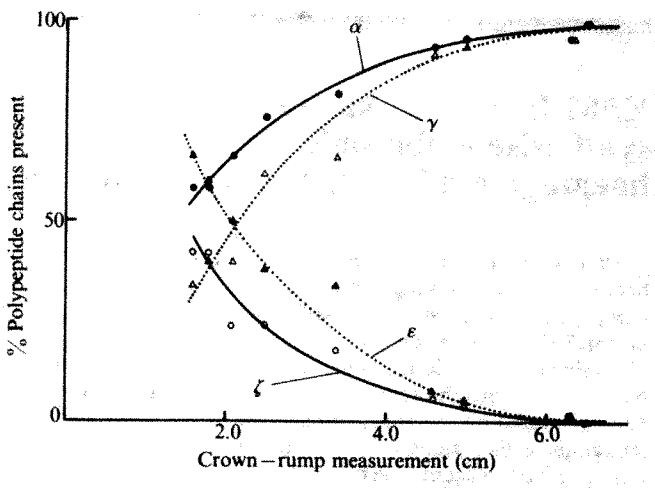

Fig. 2 Developmental changes in human globin chains. The curves have been constructed using the data in refs 1, 2 and 15 and the composition for Hb-Gower 1 $\zeta_2\varepsilon_2$.

These results confirm previous suggestions[13] that the ζ-chain is the human embryonic α-type-chain and that Hb-Gower 1 has the structure $\zeta_2\varepsilon_2$. This structure explains the finding that oxygen dissociation studies of embryonic red cells show a full cooperative effect[14]. Furthermore, the globin chain composition of the human embryonic haemoglobins corresponds to that found in other mammals. From the available data on the haemoglobins in embryos at various stages of development it can be concluded that the disappearance of the ζ- and ε-chains occurs in parallel (Fig. 2), suggesting that there is a coordinated change-over from the production of the embryonic ζ- and ε-chains to the fetal α- and γ-chains which occur at about the same time as the liver replaces the yolk sac as the main site of erythropoiesis.

We thank Mr D. Paintin and the theatre staff of the Samaritan Hospital for Women for their help, Professor R. R. Porter and Dr J. Gagnon for the use of the protein sequencer, and Mr L. Jacob for the cell separations. The work was supported by the MRC.

Note added in proof: Proudfoot and Baralle[16] have recently cloned a human ε-globin gene. The DNA sequence of a fragment of this gene gives an amino acid sequence which corresponds exactly with residues 61–100 in Fig. 1.

K562 human leukaemic cells synthesise embryonic haemoglobin in response to haemin

STUDIES of the regulation of human erythropoiesis and haemoglobin synthesis at different phases of development are hampered by the lack of a self-sustaining culture in which erythroid differentiation can be examined, and by difficulties in obtaining erythropoietic tissue in embryonic and early fetal life[1]. New insights into the regulation of murine erythropoiesis have been obtained by the study of established cultures of erythroleukaemic cells (Friend cells) which can be induced to differentiate *in vitro*[2]. Recently, Andersson *et al.*[3,4] have reported that the K562 human cell line, obtained from a patient with an acute transformation of chronic myeloid leukaemia (CML) has properties in common with erythroid cells. In particular, cells of this line contain glycophorin and spectrin in their membranes and synthesise minute amounts of haemoglobin, detectable by radioimmunoassay. We have investigated the capacity of these cells to differentiate *in vitro* and report here that they are induced by haemin to synthesise large amounts of haemoglobin; preliminary analysis indicates that this is predominantly of the embryonic type.

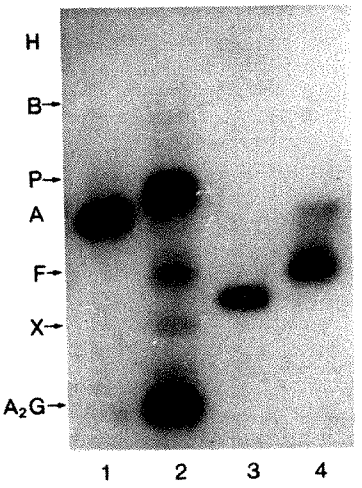

Fig. 1 Cells were grown for 6 days in the presence of 0.1 mM haemin. They were then spun down, washed three times in Hank's balanced salt solution and the final packed cell pellet resuspended in an equal volume of distilled water and lysed by three cycles of freeze/thawing. Stroma was spun out at 2,000 r.p.m. for 10 min and 40,000 r.p.m. for 45 min. Haemoglobins were separated by starch gel electrophoresis at *p*H 8.6 (ref. 6). Bands were visible with the naked eye and stained for photography with benzidine[6]. Bands in the sample (channel 2) were identified as Hb-Bart's (B), Hb-Portland (P), Hb-F, Hb-X and Hb-Gower 1 (G) by reference to the following standards: channel 1, Hb-A + Hb-A_2; channel 3, Hb-Q and Hb-H; channel 4, Hb-A + Hb-F.

Various potential inducers, including dimethyl sulphoxide, *n*-butyric acid, *N*-methylacetamide and hexamethylenebisacetamide, were tested for their effect on K562 cells and proved ineffective at concentrations that induce Friend cells to synthesise haemoglobin. However, K562 cells grown in the presence of haemin synthesised large amounts of haemoglobin. The cells were subcultured twice weekly in RPMI-1640 medium containing 10% heat-inactivated fetal calf serum. Haemin was added to cultures in logarithmic growth to a concentration 0.1 mM. The presence of haemoglobin was confirmed by absorption bands at 540, 576 and 415 nm and quantitated at 415 nm (ref. 5). Cells cultured with haemin accumulated 3 pg haemoglobin compared with 0.3 pg without haemin. The haemoglobin seemed to be relatively evenly distributed within the cells and we did not observe the benzidine-positive particles reported by Andersson *et al.*[4]. Shedding of cytoplasmic blebs was observed but was rare and was not greater than seen in control cells.

Cells were grown for 6 d with 0.1 mM haemin, lysed with 1 volume of water, the membranes removed by centrifugation and the haemoglobin analysed by starch gel electrophoresis[6] (Fig. 1). Two major haemoglobin components were found, one migrating slightly faster than a Hb-A marker in the position of the embryonic haemoglobin, Hb-Portland ($\zeta_2\gamma_2$)[7] and the other slightly more slowly then Hb-A_2 in the position of another embryonic haemoglobin, Hb-Gower 1 ($\zeta_2\varepsilon_2$)[8,9]. In addition, there were trace amounts of fractions moving in the positions of Hb-F ($\alpha_2\gamma_2$) and Hb-Bart's (γ_4), and an as yet unidentified haemoglobin (fraction X) found in variable amounts in early embryos[10]. The 'Hb-Gower 1' fraction was isolated from 6-day induced K562 cells by a combination of gel filtration and DEAE-cellulose chromatography. Following digestion with trypsin, fingerprinting and staining with ninhydrin, peptides

0028-0836/79/280164—02$01.00

© Macmillan Journals Ltd 1979

were found which corresponded to ζ and ε peptides of Hb-Gower 1. The identity of peptides εI and ζV were confirmed by amino acid analysis.

Further evidence that the induced K562 cells synthesis γ-globin chains and small amounts of α-chains was obtained by incubating the cells with ^{3}H-leucine, separating the globin chains by CM-cellulose chromatography and determining the amount of radioactivity incorporated into each chain[11-12]. It was found that γ- and α-chains were labelled and that the α/γ-globin chain synthesis ratio was 0.08; no β-chain synthesis was detected. Presumably, the small numbers of α-chains synthesised in these cells combine mainly with γ-chains to produce Hb-F and the remainder of the γ-chains are associated with ζ-chains in Hb-Portland, the excess forming the γ_4-tetramers of Hb-Bart's[1]. It has previously been shown that ζ and ε chains are not recoverable in this chromatographic system[9,13].

The reason for the induction of embryonic haemoglobin synthesis in this cell line is not clear. Neither embryonic nor fetal haemoglobins have been found in association with adult CML[14]. The electrophoretic pattern of K562 cell haemoglobin corresponds closely with that observed in haemoglobins from purified embryonic erythroblasts[7-10]. The subunit compositions of the human embryonic haemoglobins are now known[7-9,13,15] although the amino acid sequences of their component chains are still incomplete. The present observations on the haemoglobins of K562 cells suggest that these cells may offer a source of embryonic haemoglobins for the further elucidation of their structure and function, and that they may provide a useful model for studying the developmental biology of human embryonic erythroblasts and for examining the mechanism of the switch from embryonic to fetal haemoglobin synthesis.

Induction of sporulation in *Bacillus brevis* by peptide antibiotics

THE regulatory mechanisms of the process of bacterial sporulation are unknown, although some authors have speculated that sporulation and the synthesis of peptide antibiotics are somehow connected[1-4]. Paulus and coworkers proposed that tyrocidine and gramicidin D, both synthesised by *Bacillus brevis*, may interact with the transcriptional process during sporogenesis[5].

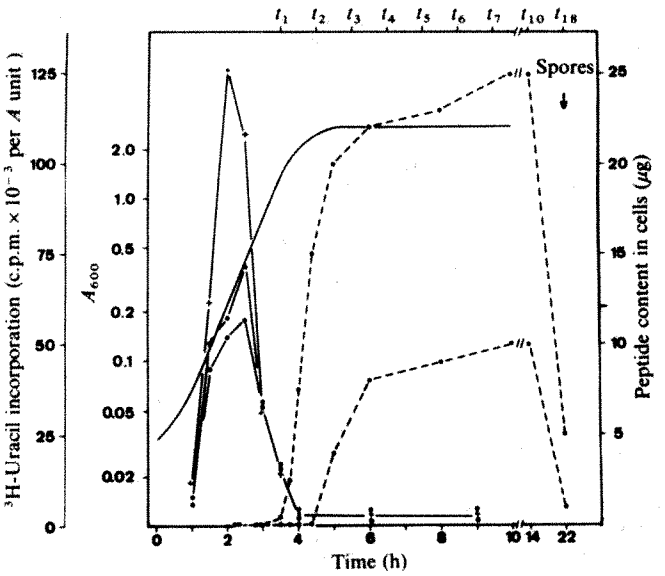

Fig. 1 *Bacillus brevis* (ATCC 8185) cells were cultured in Hanson's medium[7] at 37 °C with aeration in a water bath shaker. Growth was followed as a function of time by measuring the absorbance at 600 nm (———). One *A* unit corresponds to 7×10^6 cells ml^{-1}. At indicated times 1-ml samples were incubated with 20 μg of tyrocidine (●——●) (Serva), gramicidin D (Serva) (○——○) or without antibiotics (+——+) for 10 min and then supplemented with 0.2 μCi of ^{3}H-uracil (Amersham Buchler, specific activity 48 Ci mmol^{-1}). After 5 min incubation at 37 °C, samples were treated with trichloroacetic acid (final concentration 5%) at 0 °C. The acid-precipitable material was collected on glass fibre filters and the radioactivity measured in a scintillation counter. Radioactivity as c.p.m. per *A* unit was plotted against time of incubation. In parallel, the tyrocidine and gramicidin D content of cells was estimated by Sephadex L-20 column chromatography according to the method of Bartley *et al.*[8]. The tyrocidine (●---●) and gramicidin D content (○---○) is plotted as μg peptide in cells in 1 ml of the culture.

They have isolated a mutant of *B. brevis* which is unable to synthesise gramicidin D and which produces defective spores. The defects could be cured by exogenous gramicidin D, suggesting that this peptide is involved in sporogenesis[6]. In this report we demonstrate that sporulation of early vegetative growing *B. brevis* cells can be induced by exogenous tyrothricin, a mixture of tyrocidine and gramicidin D, provided that the cells are exposed to a culture medium lacking the nitrogen source. The induction of sporulation occurs concomitantly with a significant increase in RNA synthesis. The results suggest that sporulation and the action of these two peptides are causally connected. Both peptides may play a positive regulatory role in cell differentiation.

Figure 1 shows some characteristics of a *B. brevis* culture grown in Hanson's medium[7]. The beginning of spore formation can be detected microscopically at t_4, which corresponds to stage III of the sporulation as defined for *Bacillus subtilis*[2]. Spores are released at t_{18}. The production of tyrocidine begins at t_0, and that of gramicidin D between t_1 and t_5. From t_3 the peptide concentration in the cells increases only slightly. Free spores, however, contain only 20% of the tyrocidine and 10% of the gramicidin D found in sporulating cells. We investigated the RNA synthesis of cells at different times during growth by testing their ability to incorporate tritiated uracil. Figure 1 shows the uracil incorporation into acid-precipitable material within 5 min. The uptake increases up to the early logarithmic growing phase, decreases in the mid and late logarithmic phase and becomes low in sporulating cells. This decrease could reflect a lowered permeability of the cells for uracil. The uracil incorporation was also studied in the presence of 20 μg ml^{-1} of tyrocidine or gramicidin D (Fig. 1). At the beginning of growth the cells were relatively insensitive to

0028-0836/79/280165—02$01.00
© Macmillan Journals Ltd 1979

the peptides, but became sensitive in the early logarithmic phase; their RNA synthesis was dose-dependently inhibited by the peptides (not shown). This sensitivity decreased when the cells were in the mid logarithmic phase and, finally, the cells became completely insensitive.

Based on the observation depicted in Fig. 1 we tried to induce sporulation in cells at different stages of growth by the addition of tyrothricin, the natural mixture of tyrocidine and gramicidin D (about 2:1). The addition of tyrothricin to mid and late logarithmic cells had no effect on sporulation: treated and untreated cells started to sporulate within the same time. Addition of tyrothricin to early logarithmic cells inhibited RNA synthesis and at higher concentrations led to cell death.

In another approach cells were grown in Hanson's medium up to 0.2–0.3 *A* units, at which their uracil incorporation was sensitive to exogenous peptides, and were then transferred to a modified medium defined by Mach[9] containing glycerol as the carbon source but no nitrogen (C^+N^- medium). On addition of tyrothricin these cells began to sporulate and 5 h later had the microscopical appearance of prespores of stage III. The number of sporulating cells was dependent on the tyrothricin concentration (not shown).

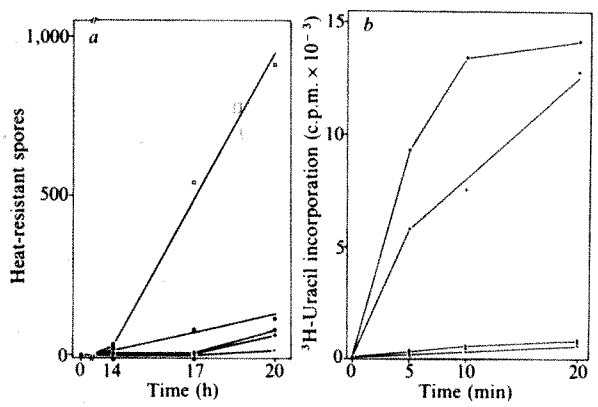

Fig. 2 The effect of tyrothricin on the formation of heat-resistant spores and on RNA synthesis of *B. brevis*. Cells were grown in Hanson's medium to an absorbance of 0.2, then filtered, washed and suspended in C^+N^- medium in the presence of 0 (+——+), 5 (△——△), 10 (○——○), 20 (●——●) and 40 (□——□) μg ml^{-1} of tyrothricin. *a*, After incubation for the indicated times at 37 °C, samples were heated for 20 min at 80 °C. Aliquots were plated on agar plates containing the components of Hanson's medium. The number of colonies was plotted against incubation time. The total number of viable cells was estimated by plating as 10^4. *b*, After 14 h incubation in C^+N^- medium 1-ml samples of the culture were incubated with 0.2 μCi of ^{3}H-uracil (Amersham Buchler, specific activity 48 Ci mmol^{-1}). At the indicated times the uracil uptake was stopped by the addition of trichloroacetic acid and the precipitates then treated as described in Fig. 1. The ^{3}H-uracil incorporation was plotted as c.p.m. against incubation time.

Figure 2*a* shows the onset of the formation of heat-resistant spores and indicates that at low tyrothricin concentrations only a few spores become heat resistant. At concentrations comparable with that extracted from sporulating cells (Fig. 1) there is a dramatic increase in heat-resistant spores, whereas in the absence of tyrothricin only a few heat-resistant spores are found after 20 h. We conclude from these results that exogenous tyrothricin induces the sporulation process of early vegetative cells. A specific metabolic situation due to the absence of nitrogen might be a prerequisite for the sporulation-inducing activity of the two peptides. In a parallel experiment, cells were incubated in C^+N^- medium in the presence of equivalent amounts of either gramicidin D or tyrocidine. With gramicidin D no prespores were detectable; with tyrocidine less than 10% of the cells formed prespores after 14 h. These results clearly indicate that the induction of sporulation must result from specific actions of both peptides.

If early vegetative cells incubated in C^+N^- medium in the presence of tyrothricin undergo sporulation they may exhibit rates of RNA synthesis different from those of cells starved in the same medium but in the absence of tyrothricin. This was tested by transferring early vegetative cells into C^+N^- medium with or without tyrothricin. After incubation for 14 h the cells were tested for their RNA synthesis. As shown in Fig. 2*b*, the rate of uracil incorporation is largely increased by tyrothricin at concentrations necessary for the induction of sporulation (Fig. 2*a*).

How might tyrocidine and gramicidin D act at the molecular level? Earlier studies indicated that tyrocidine inhibits RNA synthesis *in vivo*[5,10] and *in vitro*[5,11], in the latter by forming a complex with the DNA[11] and interacting with the initiation process of transcription[12]. Also, gramicidin D inhibited RNA synthesis[13,14] by destabilising the open initiation complex[15]. However, when gramicidin D was added to a tyrocidine-inhibited transcription system reactivation of transcription was observed[13]. This reactivation was only partial and was specifically dependent on the RNA polymerase from *B. brevis* and on a well defined equilibrium between tyrocidine and gramicidin D[16]. Studies on the molecular mechanism of this reactivation suggested that gramicidin D interacts with the DNA–tyrocidine complex, thereby weakening the DNA–tyrocidine interaction, and thus allows the RNA polymerase to transcribe[12,17]. As both peptides affect the transcriptional process they could be involved in gene regulation during differentiation of *B. brevis*. Tyrocidine could act as a nonspecific repressor, turning off transcription, whereas gramicidin D could de-repress part of the genome to allow transcription of those genes necessary for the spore-forming process. Different RNA polymerases[18] or additional protein factors[19] might be essential for the selection of these DNA sequences. Much more work is required to verify this hypothesis. The results presented, however, suggest that the two peptides are, in fact, involved in the control of sporulation.

Bacillus megaterium resistance to cloxacillin accompanied by a compensatory change in penicillin binding proteins

BACTERIA have been shown to become resistant to β-Lactam antibiotics (penicillin and cephalosporins) by the following methods: decreased permeability[1,2], increased production of an enzyme (β-lactamase) which degrades the antibiotics[1], acquisition of a plasmid that produces a β-lactamase[3,4], and a decreased affinity of the lethal target for the antibiotic[5]. β-Lactam antibiotics are thought to kill bacteria by interfering with the terminal stages of cell wall biosynthesis[6]. The cross-linking of the cell wall by a transpeptidase enzyme has been implicated as the probable target site[7,8], although inhibition of a carboxypeptidase[9] and stimulation of autolytic activity[10] have also been proposed. It has been suggested that penicillin is a transition state analogue of the D-alanyl-D-alanine moiety of the donor molecule in the transpeptidation reaction[11] and that penicillin binds covalently to the transpeptidase[7]. Investigations therefore concentrated on enzymes which could fix penicillin in bacterial membranes[12,13]. Bacteria contain multiple penicillin binding proteins (PBPs) and it is important to identify which one is the lethal target. One approach used in this laboratory has been to purify the individual PBPs and investigate their enzymatic activity, although it was realised that solubilisation might lead to inactivation. In *Bacillus megaterium* the only PBP shown to possess enzymatic activity was PBP 5 (ref. 14) (the one of lowest molecular weight), and this was the D,D-Ala carboxypeptidase, which is much less sensitive to β-lactams than is growth of the organism[15]. Despite the lack of enzymatic activity the affinity of the remaining PBPs 1–4 for benzylpenicillin could be measured in whole cells. PBP 1 was the only protein that interacted covalently with benzylpenicillin at the lowest concentration of the antibiotic that would inhibit growth, and it was therefore proposed to be the lethal target[16]. An alternative approach is to determine which PBPs become altered as an organism develops resistance to an antibiotic. This method has shown that resistance can be due to a PBP having a decreased affinity for a β-lactam antibiotic. Using this technique PBP 2 has been identified as the lethal target for mecillinam in *Escherichia coli*[5] and for cloxacillin in *Bacillus subtilis*[17]. However, in this report a new mode of resistance is described in which there is a purely quantitative change in the ratio of PBP 1 to PBP 3 as resistance to cloxacillin develops in *B. megaterium*. Thus, resistance results from a decrease in the level of the lethal target which is compensated by an increase in a less sensitive target.

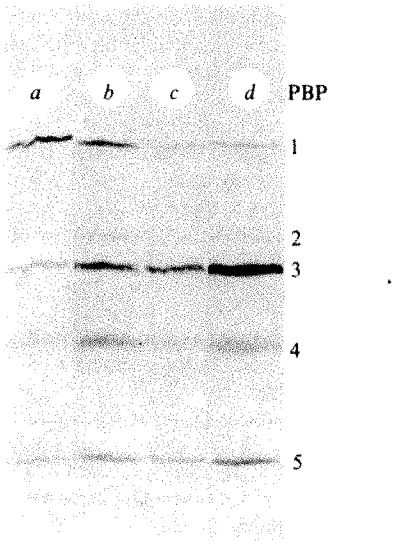

Fig. 1 Penicillin binding proteins (PBPs) of the parent and cloxacillin-resistant mutants of *B. megaterium*. The PBPs were examined as described in ref. 14. Protoplast membranes were prepared from exponentially growing cells and treated with ^{14}C-benzylpenicillin (10 μg ml^{-1}) for 10 min at 37 °C. The proteins were then fractionated by SDS-polyacrylamide slab-gel electrophoresis and the PBPs detected by fluorography: *a*, parent; *b*, XR2r; *c*, XR2; *d*, XR3.

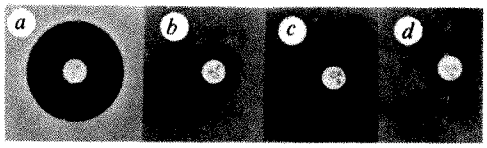

Fig. 2 Cloxacillin sensitivity of the parent and mutant organisms. Bacteria were grown in Penassay broth to a density of 0.4 mg dry wt per ml; 0.2 ml cells were added to 20 ml Penassay agar at 46 °C and overlaid onto a 9-cm plate containing 30 ml Pennassay agar. Cloxacillin sensitivity disks (Mast) were applied to the centre of each plate and diffusion allowed to occur at 4 °C for 2 h. Plates were incubated overnight at 37 °C: *a*, parent; *b*, XR2r; *c*, XR2; *d*, XR3.

Spontaneously resistant bacteria were isolated in a stepwise fashion[17]. *Bacillus megaterium* was grown on plates of Penassay agar containing cloxacillin at 37 °C. Cloxacillin was chosen to avoid selection of β-lactamase-producing organisms as it is not degraded by the β-lactamase from *B. megaterium*. A resistant mutant, designated XR2, was then purified by three rounds of single colony isolation. XR2 was filamentous and grew more slowly (mean generation time 40 min) than the rod-shaped parent (mean generation time 25 min). Membranes were prepared from XR2, treated with ^{14}C-benzylpenicillin, the proteins fractionated by SDS-polyacrylamide slab-gel electrophoresis and the PBPs detected by fluorography[18,19]. The results indicated an increase in the amount of PBP 3 and a decrease in PBP 1 (Fig. 1*c*) compared with the parent (Fig. 1*a*).

If the ratio of PBP 3 to PBP 1 is important in the development of cloxacillin resistance, one would expect a further increase in this ratio if the PBPs are examined in a mutant with an increased resistance to cloxacillin. Such a mutant (XR3) was derived from XR2, and was again filamentous and grew more slowly (mean generation time 60 min) than XR2. The PBPs of mutant XR3 were examined and the ratio of PBP 3 to PBP 1 had increased (Fig. 1*d*) relative to XR2. The fact that the cloxacillin-resistant mutants grew more slowly than the wild type suggests that there would be a selective pressure to revert to the wild type when the resistant mutants were grown in the absence of cloxacillin. In an attempt to obtain such revertants mutant XR2 was grown overnight in glucose-limited batch cultures until a morphological change was detected (eight successive subcultures at 24-h intervals). This change involved a more obvious and frequent septation of the filaments. An organism was purified through two rounds of single colony isolation on solid media and designated XR2r (a partial revertant). When the PBPs of XR2r were examined the ratio of PBP 3 to PBP 1 was found to have decreased (Fig. 1*b*) relative to XR2. The growth rate of XR2r had increased (mean generation time 35 min) and the cloxacillin resistance had decreased relative to XR2.

Thus, we have a series of three mutants in which increasing resistance to cloxacillin (Fig. 2) is related to an increase in the ratio of PBP 3 to PBP 1 (Fig. 1), a decreasing growth rate and filamentation of the organism. To ascertain whether any change in the affinity of the PBPs for cloxacillin had a role in resistance, the sensitivity of the five PBPs was measured for all the mutants (see Fig. 3 for results with the parent and XR3). No change in the affinity of PBPs for cloxacillin in the parent and mutants was detected. However, a difference was observed in the sensitivity profiles of PBP 1 and PBP 3. Cloxacillin bound to PBP 1 of all strains at low concentration (without saturating the protein completely) but required a high concentration (>100 μg ml^{-1})

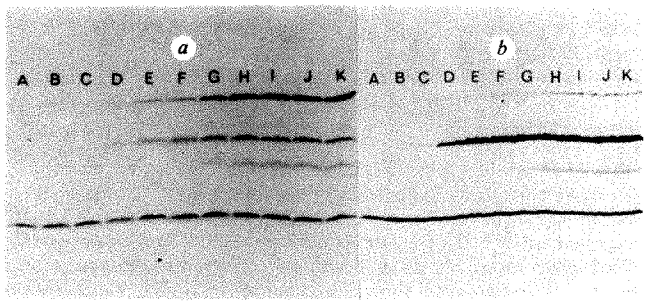

Fig. 3 Sensitivity of penicillin binding proteins (PBPs) to cloxacillin in the parent (*a*) and XR3 (*b*). As radioactive cloxacillin was not available the sensitivity of PBPs to cloxacillin was measured by prelabelling the PBPs with unlabelled cloxacillin followed by treatment of the membranes with an excess of ^{14}C-benzylpenicillin which will bind to PBPs unoccupied by cloxacillin (as described for cephalosporins in ref. 14). Experimental details were as for Fig. 1 except that membranes wkincubated with cloxacillin for 10 min at 37 °C before addition of ^{14}C-benzylpenicillin. The concentrations of cloxacillin were (μg ml^{-1}): (A) 100, (B) 30, (C) 10, (D) 3.0, (E) 1.0, (F) 0.3, (G) 0.1, (H) 0.03, (I) 0.01, (J) 0.003, (K) 0.001.

to inhibit completely the subsequent binding of ^{14}C-benzylpenicillin. In contrast, PBP 3 was saturated by cloxacillin at approximately 30 μg ml^{-1} but did not apparently interact with the antibiotic at concentrations lower than 3 μg ml^{-1} (Fig. 3). It is the sensitivity to low concentrations of cloxacillin which is important as the minimum growth inhibitory concentration for the parent is 0.08 μg ml^{-1} (ref. 15).

If the role of PBP 1 in cellular growth can be taken over by PBP 3 then the organism would become more resistant to cloxacillin if PBP 3 was less sensitive to the antibiotic than PBP 1. This situation is apparently fulfilled in the cloxacillin-resistant mutants reported here. There is a 1.5-fold increase in PBP 3 and a 10-fold decrease in PBP 1 in mutant XR2 compared with the parent strain (calculated by standardisation with PBP 5 which is assumed to be unaltered in quantity in all the organisms as it can be ruled out as the lethal target[14,15]). This may well be sufficient to alter the cloxacillin sensitivity of the organism. Compensatory changes in PBPs have also been observed in *E. coli* where supersensitive mutants lacking PBP 1Bs partially reverted to normal sensitivity to β-lactam antibiotics and this change was accompanied by an increase in PBP 1A and PBP 2 (ref. 20). The results also indicate that PBP 1 is the lethal target for cloxacillin in the wild-type *B. megaterium* and this agrees with the results obtained by a different method with benzylpenicillin[16].

Influence of leaves on sporophore production by fungi forming sheathing mycorrhizas with *Betula* spp.

MOST of the intimate and often beneficial associations formed between plant roots and some soil fungi can be classified as either endomycorrhizas of various types or sheathing (ecto-) mycorrhizas[1,2]. The latter, in which colonised roots are shorter and thicker than their uncolonised counterparts, are mainiy attributed to basidiomycetous fungi that produce sporophores (toadstools) typical of the Agaricales. Sometimes fungi forming sheathing mycorrhizas produce large numbers of sporophores. P. Larsen, quoted by Romell[3], estimated sporophore production by the mycorrhizal *Suillus bovinus* (Fries) O. Kuntze to be about 180 kg (dry weight) per hectare per yr. Although their evidence is questionable, experiments done by Romell[4] and Laiho[5] suggest that the mycorrhizal *Boletus subtomentosus* Fries and *Paxillus involutus* (Batsch ex Fr.) Fr. usually form sporophores only if they are organically linked to living trees. Hacskaylo[6] found that shading foliage of *Pinus virginiana* Mill decreased sporophore formation by *Thelephora terrestris* Fr. The results reported here extend the understanding of this relation by showing that sporophore production by some mycorrhizal associates of birch (*Betula* spp.) is strongly dependent, in the field, on the presence of green foliage.

Two experiments, done at the Bush Estate (lat. 55°52′ N) 10 km south of Edinburgh, are described here. In one, sporophore production was related to the different rates of natural autumnal leaf yellowing found in saplings grown from seeds of *Betula pendula* collected by Roth from three widely spaced locations, whereas in the other, the effects of experimental defoliation were investigated.

Seeds of *B. pendula*, collected from natural stands at lat. 50°40′ N (southern England), 57°20′ N (Latvia) and 66°30′ N (northern Sweden), were treated with Captan, a 75% fungicidal dust of *N*-trichloro-methyl-mercapto-4-cyclohexene-1,2-dio-carboximide, before being sown on 7 January 1971, germinated and subsequently transplanted to pots (approximately 100-mm diameter) of partially sterilised John Innes type compost. After being grown in a glasshouse for 10 months and then hardened-off, three replicate saplings of each seedlot (provenance) were planted in November 1971. They were spaced 3 m apart, within and between rows, in three randomized blocks on an adequately drained medium silty loam soil where their roots were colonised by naturally occurring mycorrhizal fungi. During each succeeding autumn and at intervals of about 2 weeks the position of every sporophore was recorded for each tree. At the same time a note was made of 'percentage leaf yellowing', an integrated measure of yellowing and defoliation.

In 1975, 4 yr after planting, it was apparent that the origin of the *B. pendula* seeds (provenance) greatly affected the production of sporophores, mostly basidiomycetous, but also a few of the ascomycete *Peziza badia*, Persoon ex Mérat, a pattern confirmed in 1976 and 1977. Whereas 81, 150 and 760 sporophores were associated with each tree of southern origin (lat. 50°40′ N) in 1975, 1976 and 1977, respectively, only 29, 53 and 370 were found around trees of more northerly origin (lat. 57°20′ N), with virtually none, zero, zero and three, associated with those from the most northerly location (lat. 66°30′ N) (Fig. 1). In Autumn 1977 the number of species of sheathing mycorrhizal fungi producing sporophores increased from three associated with the 'Swedish' trees (*Hebeloma crustuliniforme* (Bull. ex Saint-Amans) Quélet, *Hebeloma* sp. and *Inocybe lanuginella* (Schroet.) Lange) to 10 with the southern England provenance which had many specimens of the types already mentioned and also *Cortinarius* sp., *H. fragilipes* Romagnési, *H. mesophaeum* (Pers. ex Fr.) Quélet *H. sacchariolens* Quélet, *Laccaria laccata* (Scop. ex Fr.) Cooke, *L. proxima* (Boud.) Pat.,

Lactarius pubescens (Fr. ex Krombh.) Fr. and *Leccinum scabrum* (Fries) S. F. Gray.

Total numbers of sporophores, irrespective of species, were inversely related to rates of foliar yellowing. Whereas virtually none was associated with trees grown from seed from lat. 66°30′ N, which were completely defoliated in mid-August, many occurred where yellowing was delayed until late September (57°20′ N) and October (50°40′ N) (Fig. 1).

Because numbers of sporophores associated with *B. pendula* grown from seeds from different latitudes were systematically and inversely related to the rates of natural foliar yellowing, the effects of experimental defoliation (with scissors) were tested during 1978 on 192 saplings of *B. pendula* and *B. pubescens* Ehrh., which were aseptically and vegetatively propagated and planted in 1975. They were arranged in eight randomised blocks each testing $24(2\times3\times4)$ factorially arranged treatments including complete defoliation on either 25/26 July or 22/23 August compared with controls subject to natural defoliation which started at the end of September and reached 39% and 86% on 5 October and 3 November, respectively.

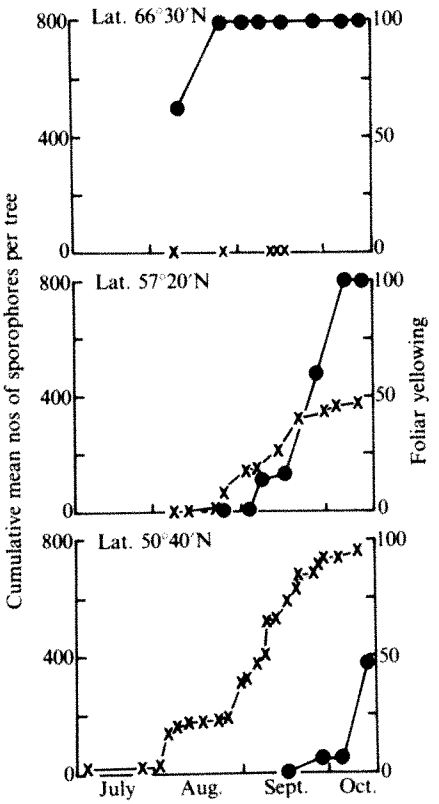

Fig. 1 Patterns during 1977 (6 yr after planting) of seasonal leaf yellowing (●), and the occurrence of sporophores (×) of sheathing mycorrhizal fungi associated with *Betula pendula*, when saplings from seed collected at three different latitudes were grown at lat. 55°52′ N (Bush Estate, near Edinburgh).

During 1978 sporophores, which appeared unusually early, were recorded at least twice during each of the six observation periods (A–F) from July to November (Fig. 2). By the end of July sporophores were associated with 25 of the 64 replicate control trees. A peak of 56 was reached in September/October before sporophore production ceased in November. From July to October numbers of newly produced sporophores ranged from 7.8 to 12.6 per tree in the different 3–4 week periods of observation (Fig. 2), contributing to a seasonal total, based on geometric means, of about 45.

During July and early August sporophore production around trees to be defoliated on 22/23 August was similar to that in the control series. As observations made on 25 August indicated, sporophore production ceased immediately after defoliation, with only one tree producing two sporophores during September, contrasting with 55 control trees averaging 10 each. This result duplicates the effects of defoliation in July but, in this instance, axillary and terminal buds started to 'break' in late August with a resultant new flush of leaves. From two trees producing a total of three sporophores in August, numbers of trees with sporophores increased to 16 and 43 in September and October as amounts of foliage increased; this trend was paralleled by increased mean numbers of sporophores per tree which reached 3.8 during October.

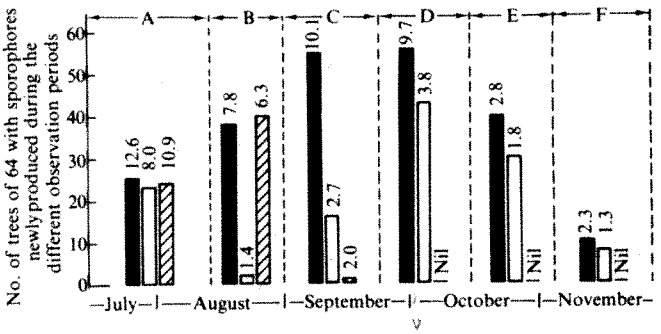

Fig. 2 Mean effects of defoliating *Betula* spp. on either 25 July (□) or 22 August 1978 (▨) on numbers of replicate trees with sporophores of associated mycorrhizal fungi newly produced within the different periods of observation. ■, Naturally defoliating set of control saplings. (Figures at tops of columns are mean numbers of sporophores per tree produced during each period; they were calculated from replicates producing at least one new sporophore during the relevant period.)

The effects of defoliation confirm that the production of sporophores by sheathing mycorrhizal fungi is disrupted when leaf function is impaired. Our observations support Lewis' contention[7] that many mycorrhizal fungi are 'ecologically obligately symbiotic biotrophs'. But, although they may be entirely dependent on their hosts for carbon[8], which they sequester, the rapidity of the responses, within 2 d of defoliation, suggest that the involvement of other substances produced by leaves, such as auxins, which can hasten the enlargement of sporophore primordia[9], should not be overlooked.

matters arising

Upper limits on production rate of NO per ion pair

RECENTLY, Fabian *et al.*[1] have suggested that the rate of production of NO per ion pair during a solar proton event should be 2–2.5 instead of the 1–1.5 used by other authors. They justify the larger rate because of rocket measurements of Arnold[2] taken during an auroral precipitation event. While Arnold's[2] measurements may be correct, we question the application of these rates to energetic solar protons as these particles mainly deposit their energy below 80 km. Here we place realistic upper bounds on the NO per ion pair production rate.

First, at altitudes between 80 and 120 km, each N or N^+ produced can potentially form one NO molecule and each N_2^+ can potentially form two NO molecules by well known ion chemistry[3–5]. Thus, by bounding the N, N^+ and N_2^+ production rates, we bound the NO production rate.

To calculate the maximum NO production rate, we follow the method of Porter *et al.*[6]. However, in this computation we assume that 20% of the $N_2(a^1\Pi_g)$ excitations form two NO molecules and that all excitations of N_2 and N_2^+ with thresholds above 9.76 eV, the dissociation energy, also form two NO molecules. This calculation yields an upper limit of 2.68 NO per ion pair for 10 keV electrons, which is larger and thus consistent with rates implied by the measurements of Arnold[2] as quoted by Fabian *et al.*[1]. Although there are some uncertainties in our calculations due to the cross-sections, we feel that our results are accurate to ±15%, in view of the use of self-consistent energy degradation methods by Porter *et al.*[6].

Second, we note that at altitudes below 80 km the maximum rate of NO production should be bounded by the production rate of N and N^+ formation because at these altitudes N_2^+ reacts almost exclusively to form water clusters and is removed[3]. In a second calculation we subtract the N_2^+-produced NO, leaving only the direct N and N^+ sources of NO and find a maximum production rate of 1.46 and 1.53 NO per ion pair for protons with energies of 20 and 200 MeV, respectively.

We thus conclude that in the altitude range below 80 km it is difficult to justify NO/ion pair rates greater than about 1.5. In fact, the NO per ion pair production rates for altitudes <80 km are probably close to the 1.2–1.3 calculated independently by Frederick[3] and Porter *et al.*[6]. However, in the thermosphere between 80 and 120 km, numbers as high as those quoted by Arnold[2] are clearly possible.

Amount is not supply rate in energy intake control

ON the theory that rate of energy supply determines intake[1], it is not as Rothwell and Stock state, "logical to assume that isoenergetic stomach loads will have similar effects on voluntary energy intake" (ref. 2), or that—when energy intake does not compensate for changes in energy expenditure—the animals may be "regulating food intake to meet their requirements for some dietary component other than energy" (ref. 3). The amount of energy in the stomach (or anywhere else) does not necessarily have a one-to-one relationship to the instantaneous delivery rate of that energy. The relationship depends on the physiological characteristics of the energy store's turnover.

We have emphasised[4–7] the relevance of others' findings that the rate of passage of energy from the stomach (and onwards to the tissues) depends to a considerable extent on the form that the energy is in, for example, the energy density of the diet[8]. We have calculated the long-term effects of some dissociations between amount and supply rate[5,6] and in the same context pointed out further such mechanistic as well as thermodynamic calculations which are required by an unmodified energy-rate or power-measuring theory of energy intake control. The report by Rothwell and Stock[2] clearly indicates the importance for theory and practice of extending the simulation work with experimental work to determine the as yet poorly analysed short- and long-term implications of satiation by energy metabolism.

ROTHWELL AND STOCK REPLY—If, as Booth claims, "the rate of energy supply determines intake", why do rats force-fed a balanced diet adjust voluntary intake such that their total energy intake is the same[1] as that of free-feeding controls? The rate of energy supply is radically different in these two situations and should therefore produce marked differences in intake; it certainly causes differences in energy retention because the force-fed rats become obese. This latter finding indicates that a greater fraction of absorbed energy is available to metabolism and should, also according to Booth[2], result in compensatory adjustments to energy intake. In our original paper[1] we suggested that the theory of intake control proposed by Booth and Toates[3,4] was unlikely to provide an explanation of our results. Given that neither the rate of energy supply nor the metabolic fate of that supply influences intake, we see no reason for modifying that statement and, as a comment on Booth's final sentence, suggest that it is

obviously necessary to extend the 'simulation work' if it is to keep pace with experimental developments.

ROTHWELL AND STOCK[1] demonstrated that partially tube-fed rats gained significantly more weight than their free-feeding controls even though both groups ate very nearly the same amount. We suggest the possibility that the weight differences result from changed levels of activity. This approach obviates the paradoxical problems suggested by Rothwell and Stock.

A single energy reservoir model is used, as the rats are mature adult males unlikely to change their fat-free weight on over-feeding. We can describe the rate of change of fat[2] quantities by the following differential equation

$$\alpha\, \mathrm{d}f/\mathrm{d}t = \varepsilon P - \mathrm{BMR} - \delta(l+f) \quad (1)$$

where α is the energy equivalent of fat, f, t is time, ε is the efficiency of food utilisation, P is the average daily food energy intake, BMR is the basal metabolic rate, l is the fat-free weight assumed to be constant or slowly varying, and δ is a constant independent of the total weight and indicates the average activity level of the rats. We have made no direct distinction between feeding and non-feeding activity of the rats. MacMillan *et al.*[3] have demonstrated densimetrically that in man the BMR is independent of the amount of fat present; we assume this to be valid in the case of rats also. Because the BMR is independent of f we can solve equation (1) directly obtaining

$$w = [(\varepsilon P - \mathrm{BMR})/\delta][1 - \exp(-\delta t/\alpha)] + w_0 \exp(-\delta t/\alpha) \quad (2)$$

where we have replaced $(l+f)$ by the total body weight w and $(l+f_0)$ by the initial total body weight w_0.

We used Kleiber's 3/4-power law[4] to deduce the BMR. The BMR of a 'standard' 65-kg man is 6.27 MJ per day (1,500 kcal d^{-1})[5]; thus, the average rat will have a BMR of 128 kJ per day. Within the rat groupings we scale the BMR by a 2/3-power law as Kleiber's rule only relates to average interspecies quantities.

To use equation (2) we take α to be 39.2 MJ per kg (9,370 kcal per kg)[5]. The value of ε is unknown but should reflect losses due to the thermic effect and the passing of small energy amounts in the faeces. Antonetti[6] used a value of 0.9 in man. We take ε to be unity, because this must be the limiting case, and apply it to both tube-fed and free-feeding rats. Table 1 shows the data of Rothwell and Stock[1] and includes the results of our calculations. There is enough information to solve equation (2) for the activity coefficient, δ (Table 1).

In each case δ was less for the tube-fed rats than for the control groups, suggesting that the observed weight gain difference can be explained by the decreased activity of the test animals. The possibility that the tube-fed rats might increase their non-feeding activity is not reflected in the decreased values of δ. The average value of the activity coefficient of the controls was (423 ± 73) kJ per kg per day; the daily activity energy expenditure was 153 ± 26 kJ.

We calculate that the average control rat expended about 54% of the total energy on all forms of activity. Rothwell and Stock[1] consider activity energy to be negligible; Miller and Mumford[7] deduce that about 3% of the total energy is expended on activity by severely exercised rats by applying a fixed energy expenditure factor of 0.5 kcal per kg per km to rat, man and elephant. Morrison[8] has measured spontaneous activity calorimetrically and reports it to be 25% of the total energy expenditure. Our results agree slightly better with those of Morrison[8] by assuming ε to be 0.9 (ref. 6). Repeating the numerical calculation in this case we find δ to be 333 ± 56 kJ per kg per day, giving a 48% value for activity.

We can deduce the level of activity for rats completely tube-fed. We have plotted in Fig. 1 the ratio of the activity coefficient of the tube-fed rats to that of the control group as a function of the fraction of tube-fed energy. We have included the limiting point for no tube-feeding. The linear fit extrapolated to the limit of complete tube-feeding gives a value of 0.25. We conclude that 75% of caged rat activity is food related. This value cannot be compared with Morrison's results[8] because our definition of food-related activity is broader.

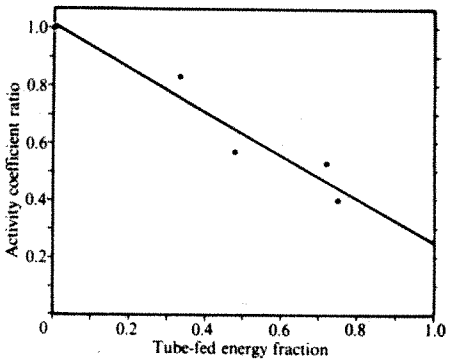

Fig. 1 The ratio of the activity coefficient of the tube-fed rats to that of the appropriate control group plotted as a function of the fraction of tube-fed energy. The point on the ordinate is the limiting value of the ratio for no tube-feeding. The other points are experimental. The linear least-squares fit is displayed and interpolates to a value of 0.25 for complete tube-feeding.

Equation (2) essentially describes the exponential increase of fat and allows an interesting speculation. The equilibrium value is approached to within $1/e$ of its final value in a time given by α/δ which is 93 ± 16 days. If a parameter proportional to the fat store size is sensed as an 'error signal' for a regenerative control process, and if the sensing time is similar to the rise time of the fat store, we can conclude that experimental studies dealing with problems of control must be carried out for times of the order of or longer than 93 days.

Tube-fed	9	400	489	367	21	74.7	136	147

ROTHWELL AND STOCK REPLY—We need not go beyond Alpert's first paragraph to see that the paradox in the control of energy intake revealed in our paper and further discussed below (see reply to Mrovosky) has been confused with the question of why tube-fed rats gain more weight than control rats on identical energy intakes.

Our paper was not intended to explain this effect of 'meal-feeding' on energy metabolism; we simply took advantage of this well known effect so as to induce excessive weight gains and observe the effect on residual voluntary intake. We were concerned with how intake is related to the regulation of energy balance whereas Alpert is concerned with mechanisms responsible for the greater efficiency of energy utilisation in tube-fed rats.

Although Alpert's theoretical considerations are not pertinent to the paradox discussed in our paper we would, nevertheless, like to make the following points.

First, differences in body energy gain in animals on identical metabolisable energy intakes must be due to differences in energy expenditure. Apart from the 'basal' contribution, expenditure can vary due to changes in activity and/or the efficiency of energetic transformations within the body (that is, diet-induced thermogenesis or the heat increment of feeding). Alpert assumes that the efficiency of energy utilisation within the body is constant and therefore ascribes differences in total energy expenditure entirely to changes in activity. He states that this is logical and mathematically consistent but ignores the fact that it is just as logical and mathematically correct to fix activity at a constant level and ascribe the changes in total energy expenditure to differences in the efficiency of utilisation.

Second, there is evidence that metabolic efficiency is greater in meal-fed animals (see ref. 1 for review). Activity may also be affected but observations have not revealed any noticeable differences. Furthermore, we have calculated the difference in activity that would be required to explain the greater energy retention of our tube-fed rats. Parkes[2] has determined the energy cost of walking in the rat to be 0.105 kJ per km per g body weight. Applying this value to the rats which were tube-fed 74% of control intake, we estimate that control rats would have to walk 2,000 m per day more than tube-fed rats to explain the differences in energy retention. Note that these were adult rats housed in pairs in cages with floor dimensions of 40 cm × 30 cm, so that it is extremely unlikely, if not physically impossible, for two rats to each walk 2 km per day in these conditions—and even this assumes that tube-fed rats were completely inactive.

In conclusion, we are not convinced by Alpert's deductions concerning the cause of the greater energy retention in our tube-fed rats and he has not attempted to explain why these rats failed to depress voluntary intake to compensate for their excessive weight gain.

Rothwell and Stock's paradox and multiple controls of feeding

ROTHWELL AND STOCK[1] reported recently that rats tube-fed a balanced diet intragastrically ingest overall (the tubed plus the voluntary intake) the same amount of energy as do control rats. However, the tube-fed rats gained more weight, presumably because of increased efficiency of energy utilisation associated with receiving intragastric loads in a few discrete meals. They considered it paradoxical that the total energy intake was not affected by the fate of the ingested energy.

These are interesting results, but how paradoxical they appear may depend on how strongly one considers energy content of the body to be the fundamental determinant of food intake. Most people, however, would probably accept that intake is under multiple controls, including such factors as palatability, previous conditioning and cost in obtaining food. Energy content of the body could be one factor in the control of food intake but is not necessarily the most important factor in every instance[2].

To determine if energy content of the body is one factor that affects food intake, or utilisation, in the intragastric tube-feeding situation, further analyses of the data might be useful. For instance, intake during the last few days of Rothwell and Stock's experiment, when the tube-fed rats were somewhat heavier than controls, could be compared with that during the first few days when the animals were similar in weight; if there were differences, energy content of the body would be implicated. If, on the other hand, it could be shown that intake and utilisation in the intragastric tube-feeding situation are independent of body weight, this would be much more surprising than the fact that tube-fed animals fail to control their intake in a way that maintains constant body weight. However, to show conclusively that intake is independent of weight might require longer experiments involving greater weight gains than those occurring in Rothwell and Stock's study.

2. Mrosovsky, N. & Powley, T. L. *Behav. Biol.* **20**, 205–223 (1977).

ROTHWELL AND STOCK REPLY—Mrosovsky suggests further analyses of the data to see if intake and utilisation are independent of the changes in body weight occurring during the experiment. A comparison of the energy intake of tube-fed rats during the first 5 days of each experiment with the intake during the last 5 days shows that they are identical, in spite of weight gains equivalent to 20% of starting weight. Furthermore, the rate of weight gain was remarkably constant throughout each experiment, therefore suggesting that both intake and utilisation were independent of body weight. By his own admission, Mrosovsky will be surprised by these results but we would agree that a conclusive demonstration of this independence of intake and body weight probably requires longer experiments with greater weight gains.

Is the benzodiazepine receptor coupled to a chloride anion channel?

FROM their observations on the ability of several anions to facilitate the binding of ^{3}H-diazepam to membrane fragments from rat cortical tissue, Costa, Rodbard and Pert[1] have inferred that this binding site is closely associated with a chloride ion channel. Their data are qualitatively similar to ours with regard to the rank order of potency of the anions and we can confirm that the bromide ion also causes a significant increase in the affinity of the benzodiazepine receptor for the ligand diazepam without significantly affecting the total number of sites available.

Costa *et al.*[1] have drawn a correlation between the ability of various anions to enhance ^{3}H-diazepam binding and their ability to penetrate the activated inhibitory postsynaptic membrane of cat motoneurones as reported by Eccles[2]. As the binding experiments were carried out in cortical tissue membrane fragments it is probably advisable to attempt correlations with electrophysiological data on chloride channels obtained in the same region of the central nervous system. Such data are available in the literature[3] and comparison of the electrophysiological data from Eccles[2] and Kelly *et al.*[3] immediately shows that the anion-size specificity in cortical tissue is considerably less than that in the spinal cord; this may

0028-0836/79/280172-02$01.00

© Macmillan Journals Ltd 1979

be explained by the fact that the chloride channel in the spinal cord is probably glycine linked whereas that in the cortex is linked to γ-aminobutyric acid.

We wish to refine the bulk correlations attempted by Costa *et al.*[1] by ranking the ability of the various anions to facilitate specific ^{3}H-diazepam binding and attempting correlations between the rank order so obtained and the ability of these ions to reverse the cortical inhibitory postsynaptic potential (i.p.s.p.) as reported by Kelly *et al.*[3]. It is difficult to ascertain which parameter from the anion facilitation data should be selected for such a correlation: percentage increase of ^{3}H-diazepam binding at maximal facilitation, percentage increase at an arbitrarily selected ion concentration, or the lowest ion concentration at which facilitation is seen. One parameter which encompasses these various possibilities is obtained by simply measuring the area under the curves for the facilitation of specific ^{3}H-diazepam binding against ion concentration (0–200 nM) (Table 1). None of the above correlations reached statistical significance, in the latter case the correlation coefficient with the area under the curve and the percentage probability of reversal of the i.p.s.p. was 0.61 whereas with the mean time to equilibrium it was 0.28. Using the non-parametric Spearman rank test we again found no significant correlation. The major criticism which can be raised against the use of these electrophysiological data is that the technical complexity of such experiments leads to quite large standard errors. It is interesting that Araki *et al.*[4] also observed differences in the ability of various anions to penetrate the cell membrane and in this case also we have been unable to find a significant correlation with the ability of the ions to facilitate ^{3}H-diazepam binding.

An alternative explanation is that the effects of these anions are due to their chaotropic properties. This possibility is not favoured by Costa *et al.*[1] because they feel that the concentration ranges over which chaotropic properties are normally observed are generally higher than the ED_{50} values for the anions in facilitating ^{3}H-diazepam binding, and also that perchlorate, while exhibiting powerful chaotropic properties, is relatively inactive in facilitating binding. In our study F^- caused a significant though small facilitation of the binding throughout the concentration range studied (5–200 mM), and SO_4^{2-} also caused a significant facilitation at 100 mM. It should be noted, however, that the rank orders of potency of the chaotropic properties are modified by several factors and are not invariant[5]. As an example of such a situation we may cite the work of Collins and Salton[6] in which 100 mM $Ba(SCN)_2$ is nearly as effective as 1% Triton X-100 in solubilising mannan from *Micrococcus lysodeikticus* membranes while being almost completely ineffective in the case of cytochrome *c*. Until we are more familiar with the characteristics of this membrane preparation it would be unwise to draw any conclusions about the effects of chaotropic ions upon it.

Table 1 Correlation between the facilitation of ^{3}H-diazepam binding and ion concentration

Ion	Area under specifically bound ^{3}H-diazepam curve (0–200 mM arbitrary units)	Weighted half time to equilibrium[3] (T_{Cl}/T_A)	% Reversals[3]
Br^-	704	1.04	100
I^-	650	2.24	93
NO_3^-	403	0.79	75
Cl^-	399	1.0	100
F^-	258	—	33
IO_3^-	173	—	0
SCN^-	165	1.98	67
ClO_3^-	126	0.41	80

Diazepam binding assays were carried out with well washed whole brain (less medulla-pons). Membrane fragments were prepared as described previously[7]. Membrane fragments equivalent to 125 μg protein were incubated on ice with 3 nM ^{3}H-diazepam in a total volume of 1 ml 100 mM Tris-citrate buffer, *p*H 7.1, and nonspecific binding was determined by displacement of ^{3}H-diazepam with 3 μM clonazepam. Sodium salts were used throughout with the exception of NH_4SCN, and compared with the maximal level of facilitation, inhibition was found with I^- at 200 mM and SCN^- at and above 50 mM. Areas under the curves were estimated by triangulation and even if SCN^- is omitted, because of its marked inhibitory activity, correlation coefficients do not increase markedly. Attempts to draw correlations between the electrophysiological data and the lowest anion concentrations required to produce a significant facilitation of ^{3}H-diazepam binding produced even weaker correlation coefficients.

We feel that the data so far available are insufficient to distinguish adequately between the possible explanations available for the facilitation of ^{3}H-diazepam binding caused by certain anions, and that it is premature to infer a direct linkage from benzodiazepine receptor to a chloride ion channel.

7. Martin, I. L. & Candy, J. M. *Neuropharmacology* **17**, 993–998 (1978).

RODBARD, COSTA AND PERT REPLY—In our recent study[1], only five anions (I^-, Br^-, Cl^-, NO_3^- and SCN^-) of a series of 18 tested increased the affinity of diazepam binding to rat brain membranes. Confirming the report of Tallman *et al.*[2], Martin and Candy[3] have reported the enhancement of diazepam binding by γ-aminobutyric acid (GABA) and have further noted the facilitatory effect of NaCl and KCl on the GABA-enhanced binding. However, we believe that their attempt to correlate the binding data with the electrophysiological data of Kelly *et al.*[4] is spurious for the following reasons. (1) The area under those biphasic binding curves has no apparent physicochemical meaning; (2) the anions have variable inhibitiory effects; (3) Kelly *et al.*[4] pointed out that the relationship between percentage reversal and anioninic mobility "is clearly not a simple one", and that the T_{Cl}/T_A equilibrium ratios 'only give an approximate estimate of the relative mobilities'.

It seems reasonable to view the facilitatory ion effect of anions on binding as an all or none phenomenon, as Eccles[5] described anion channel permeability. Viewed this way, it is striking that the same five anions which detectably enhance diazepam binding are the five most active anions according to Kelly *et al.*[4]. In fact, the probability of this being coincidental is about 1 in 1,000.

The possibility that these anions are effective by virtue of a nonspecific chaotropic effect is extremely unlikely in our view: (1) the active anions displayed an ED_{50} in the range of 2.8–20 mM, concentrations far below those usually necessary to elicit chaotropic effects; (2) strong chaotropic agents (guanidinium) are inactive or even decrease binding of diazepam to its receptor (unpublished data); (3) anti-chaotropic agents (fluoride, sulphate, phosphate) do not reverse the iodide enhancement of diazepam binding.

In conclusion, we agree with Martin and Candy's contention that differential linkage of neurotransmitter receptors with the same anion channel is a possibility. In fact, we have previously interpreted our finding[6] of large regional differences in the ability of iodide and GABA to enhance diazepam receptor binding as indicative of differences in the extent to which GABA and diazepam receptors share the same ionophore.

Finally, we report new data which we are preparing for publication. The compound 4,4′-diisothiocyano-2,2′stilbene disulphonic acid (DIDS) is a specific anion channel blocker in the erythrocyte membrane[7], which has an anion specificity similar to that of cortical neurones. In competition experiments, DIDS can completely reverse the enhancement of diazepam binding by active anions at concentrations (ED_{50} = 100 μM) which have no effect on control binding.

Although definitive proof of the linkage of benzodiazepine receptors with anion channels will require further electrophysiological substantiation and structural biochemical evidence, we believe that the benzodiazepine binding data

strongly support the notion[6] that benzodiazepine, GABA and perhaps glycine receptors interact with the same chloride ion channels.

Another interpretation of communal breeding in green woodhoopoes

LIGON AND LIGON[1] presented information which they stated "suggests helping is a strategy for personal gain", and concluded that their observations "do not support an interpretation of helping behaviour relying on kin-selected altruism." Obtaining critical evidence on these two points is difficult, perhaps justifying presentation of preliminary data. Nevertheless, it should be pointed out that their results are open to other interpretations and, in my view, they are entirely consistent with my proposed theory[2] incorporating kin selection and individual selection, which they rejected.

Ligon and Ligon apparently invoked the personal-gain theory because the helpers showed no evidence of discrimination in their feeding of nestlings according to genetic relatedness. They did not actually demonstrate any personal gain; they merely inferred that it must exist because they saw that some helpers were not related to the young they fed. I consider this to be insufficient evidence on which to base the interpretation of personal gain. The few data presented are equally compatible with a zero-gain or even a loss (that is, altruism) hypothesis, as long as, on average, helping causes a gain in inclusive fitness to the helper. The apparent eagerness of helpers to feed young could be similarly explained.

Although personal gain to helpers by helping has been invoked by many authors and seems highly likely (for review see ref. 3), I know of no case in which a personal gain in terms of direct (individual) fitness has been convincingly demonstrated. Although there is some evidence for this[4], firm empirical data based on a strong-inference hypothesis are lacking. Apparently, Ligon and Ligon considered that their observations of a few helpers feeding unrelated young was inconsistent with kin-selection theory. They did not give their reasoning, but it seems to be based on two points: lack of discrimination of genetic relatedness in feeding efforts, and presence of presumed personal gain.

Discrimination was not evident in the few cases described, but the sample is unfortunately quite small (three cases). It may be of interest that a similar, though insignificant, lack of discrimination has been shown in jays (Fig. 1 of ref. 5). Even some parents in communal birds sometimes fail to discriminate between their own young and that of others (p. 375 of ref. 6), but one would not interpret this as evidence that parents in general have no genetic interest in their young. In any case, discrimination is not a necessary feature of kin selection[7–12], even though some authors have written as if it were[13].

Personal gain, although inconsistent with altruism, is entirely consistent with kin selection. This is not always evident in writings on kin selection[13,14], but, as clearly shown by Hamilton[11], the concept of inclusive fitness specifies that genetic costs and benefits be accounted across all relatives (not just offspring), regardless of the sign of the effect. My theory[2] for the evolution of helping was based on a combination of kin selection and individual selection. Although I called helpers 'altruists', altruism or sacrifice by the helper was not a necessary or even desirable part of the theory, which is equally applicable when personal gain to the helper is involved.

As kin selection requires neither discrimination by relatedness nor individual sacrifice, it is difficult to see how the data of Ligon and Ligon are inconsistent with kin selection. The important condition is that the indirect fitness (inclusive fitness minus direct or individual fitness[12]) be raised by helping, and the Ligons did not consider this point.

LIGON AND LIGON REPLY—Brown's major criticism of our report[1] is that we rejected his theory[2] incorporating both individual and kin selection in the evolution of avian helper systems. Actually, we questioned only kin-selected or phenotypic altruism[3,4] in one kind of bird. Because green woodhoopoes can gain breeding status and helpers by first being helpers, whether or not they are related to the nestlings aided, we suggested that helping is a strategy for personal gain. For example, older birds gain and hold new breeding positions as a result of the support provided by younger individuals[5]. The system we describe corresponds to Hamilton's[4] selected category and can also be referred to as cooperation[6], reciprocal altruism[7], reciprocity[3] or mutualism[8]. Kinship ties may or may not be present but are not required for this kind of behavioural interaction.

Brown proposes alternative explanations for our observations. We feel that because of the many unknown factors related to kin-selection theory[9] the most parsimonious explanation for avian helping behaviour is personal or direct gain[10], when this can be ascertained. Very recently, Brown[11] has acknowledged that kin selection may not always be involved in communal helper systems, and Brown and Brown[12] have urged abandonment of the term 'altruism' to refer to avian helping behaviour. Both points are addressed in our report and we support both suggestions.

Scientific R&D in France

R.W. Cahn

Le Pouvoir et la Science en France. By Pierre Papon. Pp. 315. (Editions Centurion: Paris, 1979.) Paperback Fr.65.

THIS book is one of the few detailed studies of the politics of scientific research and development in France. The author is professor of physics in one of the Grandes Ecoles, has been involved in the central planning machinery of French government, and is active in advising the French Socialist Party on matters of scientific research.

Professor Papon is extremely informative — the book is full of historical facts and figures; he is critical of French administrative procedures and again backs his criticism with much historical evidence; and in the last third of the book he steps back from the here and now to analyse, with an impressive grasp, the problems of method and objective involved in attempting to plan scientific research at all. Starting with the ideas of Bernal (from whose *Social Functions of Science* he quotes a long passage) he analyses very fairly the temptations, pitfalls and possible benefits of planning applied to science and development, and faces the inescapable conflicts between scientific research perceived as an autonomous liberal profession and science as a servant of the Commissariat au Plan.

An initial chapter reviews the history of the scientific profession in France; there is a tantalising glimpse of 'le grand patron' (he says of Pasteur that "il ne put faire triompher ses idées qu'une fois qu'il eût vaincu le scepticisme d'un patron important"), but that crucial species is not further analysed. Professor Papon then goes on to recount in detail the development and repeated changes in central scientific administration. As in Britain, the changes were many. A wilderness of advisory committees, both general and specialised, interministerial committees and delegations waxed and waned (though some, particularly the Committee of the Twelve Wise Men of which Professor Papon was a member, have shown great staying power). The CNRS, which sets up and finances research teams, and the DGRST, which administers studentships, fellowships and grants, together fulfil the functions of the SRC in Britain. Last year, the various bodies and committees were brought together under the aegis of a specialised Minister of Science — a condition which, for better or worse, Britain has not yet reached.

The author goes on to analyse in some depth the position of scientific research in universities and the Grandes Ecoles. Although recognising the major stimulus CNRS has given French science, he criticises it for having sapped the scientific independence of academic institutions: many CNRS laboratories are off-campus. The engineering Ecoles come in for special condemnation for having neglected research, and this is partly laid at the door of CNRS for being very fundamentally oriented, and partly attributed to the mathematical and analytical bent of the Ecoles, beginning with the nature of their competitive entrance examinations.

A substantial part of the book is devoted to research in industry and in the large quasi-industrial state institutions, especially the Commission à l'Energie Atomique, whose history is recounted in detail. This topic leads Professor Papon on to analyse de Gaulle's hostility to supranational (as opposed to bilateral) scientific arrangements, the cause of his unrelenting persecution of Euratom. A preference for bilateral or trilateral accords survives today: sometimes it works very well, as with the Airbus Consortium; sometimes badly, as with French attempts to foster the computer industry (again the story is told fully). Perhaps the crowning irony in French technological history, as Professor Papon describes, was the CEA's decision in 1969 to replace the home-grown graphite/gas reactors with American-style light-water reactors; Britain, which is more open to American suasions in general, has not yet been persuaded.

For a British reader, perhaps the most surprising claim made by Professor Papon is that it is virtually impossible for a research scientist or engineer to penetrate the top echolons of industrial management. He tells us that the R&D laboratory is a place of exile eschewed by ambitious would-be industrialists, and many Polytechniciens and other graduates of Grandes Ecoles, though trained formally as engineers, go straight into administration. We are often told in Britain that the French approach to engineering education as an elite enterprise ensures proper recognition of engineering skills at the highest level. Professor Papon's arguments suggest that this is only so if the engineers contrive to forget their professional origins. It would be instructive to have chapter and verse, and perhaps the Finniston Committee in the UK will provide it as part of their international comparisons.

Only part of one sentence in the book is devoted to the influence of research workers' trade unions, of which there are several in France. Could this have happened if the book had been written by an English socialist?

Professor Papon is often hard on his fellow-countrymen and on his country's institutions, but he generally documents his assertions, his reading has been catholic, and he freely makes international comparisons. This modestly priced book will be of interest and value to all those concerned with science politics, whatever their nationality. □

Marine communities

Biogeography and Adaptation: Patterns of Marine Life. By G. J. Vermeij. Pp. 332. (Harvard University Press: Cambridge, Massachusetts, and London, UK, 1978.) £17.50.

THIS thought-provoking book is mainly concerned with the influence of biological interactions, especially predation, on the architecture of hard-shelled marine organisms and on the stability and biotic history of marine communities. It is divided into three main parts and is followed by an appendix, comprehensive reference list and index. The first part points out the occurrence of gradients in shell form of gastropods, bivalves and other organisms along latitudinal gradients and with depth below the high water mark. The author suggests that these primarily reflect anti-predatory defences which are developed to a greater degree and are found in an increasing proportion of species along a gradient from high to low

latitudes. The second part is concerned with inter-oceanic differences in the degree to which predation-related adaptations in shell structure are developed, and the third part reviews inter-oceanic differences in patterns of extinction and speciation along latitudinal gradients.

One has the impression that the author has drawn on a considerable personal experience of marine communities in many parts of the world and although most of the examples are taken from the Mollusca, particularly from the shelled gastropods, this does not seriously detract from the fundamentally interesting ideas which emerge from the text. The main problem with the book is that in many ways the intuitive ideas expressed in the text are ahead of the data necessary to support them. This is due in part to the difficulty of quantifying architectural differences in shell type and partly to the global comparisons ranging through geological time. Nevertheless the trends are illustrated as far as possible by profuse photographs, although the uninitiated (including myself) may find some of these difficult to interpret.

The chapter on vulnerability to extinction in stress-tolerant, opportunistic and "biologically competent" species and its relevance to biogeography throughout an evolutionary time scale will be of particular value to scientists and senior students with interests in palaeobiogeography. Nevertheless, I personally would have felt the work as a whole to have been more satisfying if there had been some more serious attempt to quantify the trends which are illustrated in the photographs. As the author himself admits frequently in the text, a great deal more data need to be obtained to verify some of the ideas raised in the book. However, informed speculation, particularly when expressed in a thoroughly readable and lucid style as it is in this book, can play an important part in promoting new work on the nature of animal adaptation. In this respect the book is a valuable addition to the literature and represents a significant contribution to our understanding of the ways in which biological interactions influence the structural design of living organisms.

Radiation damage in semiconductor materials

Radiation Effects in Semiconductors and Semiconductor Apparatuses. By V.S. Vavilov and N.A. Ukhin. Pp. 280. (Consultants Bureau/Plenum: New York and London, 1978.) £30.

AN English translation of a scientific book by an authoritative Russian author is always of interest as an insight into Russian thinking. When the subject has strong connections with technological fields such as semiconductors and nuclear science, the interest is even greater. It is thus a disappointment to find that the original of this book was finished over ten years ago — much too long ago in a fast-developing subject such as this. Viktor Vavilov has done distinguished work in the field of radiation damage in silicon, especially in the fields of photoconductivity and photovoltaic effects, and such work requires an extensive background knowledge of radiation damage in bulk silicon and germanium. The surveys of these latter topics are useful, especially as the classic work in this field was done before 1967. Moreover, the accounts given of the carrier removal rates and other defect phenomena in these semiconductors include summary tables which can be used by research workers for a long time. On the other hand, the fact that the semiconductor technology discussed is over 12 years old lends to other parts of the book an overwhelming impression of ancient history. In addition, the crediting of work to various authors is vaguely done, so that many sections do not even serve as historical guide. No specifically Russian insights are revealed, as much of the best work discussed is American. Evidence that the present anonymous translator was not an expert in the field comes from the mangled versions of US workers' names (Prines for Pines; Byub for Bube, and so on — products of translation into Russian and then back to English). "Apparatus" in the title should, of course, read "Device".

The surveys of radiation damage and transient radiation effects seem fairly complete, except for a curious (even political?) omission of the work of Rappaport, Wysocki and co-workers on lithium doping in silicon. The discovery by this group of the action of lithium in the 'healing' of radiation damage in solar cells was an astonishing technological application of basic radiation damage physics. Could it be that Vavilov does not wish to admit that, although engrossed in basic studies of lithium in damaged silicon, his group missed this particular trick; or is there some defence application of the principle which puts the work outside the realm of discussion in the USSR?

Due to lack of other good summaries of the field, this book will find a place on the shelves of research workers, but its main rôle is that of an historical record.

Andrew Holmes-Siedle is Consultant to the Physics Department of the Fulmer Research Institute (Slough, UK) in the fields of solid-state physics and radiation physics.

Mechanical properties of ceramics

Mechanical Behaviour of Ceramics. By R.W. Davidge. Pp. 165. (Cambridge University Press: Cambridge, 1979.) £15.

THIS book fulfils a need that has existed for some time now. The mechanical properties of ceramics have been a subject of comparatively intense research for some two decades or more — in fact, ever since the 1950s, when the hope was expressed that these brittle materials might be made tougher by more research, the optimism centring initially at any rate on the prospects for improvements in the ductility of polycrystalline ceramics by analogy, I suspect, with the history of improvements to cast iron. As becomes apparent from reading this book these hopes were not well founded. It would be hard to find a better author for this book than Dr Davidge who has been at the forefront of research in this subject for numberous years.

The layout of the book is essentially classical, mapping out our knowledge of the factors affecting the intrinsic elastic and strength properties of ceramics, the treatment of flaws through fracture mechanics and finally reviewing the essential details of plasticity and the reasons for many ceramics being inherently strong. These areas are reviewed in the first 5 chapters of the book.

Chapters 6-9 deal with the fracture strength,impact resistance, toughness, thermal shock, and last but not least, engineering design data. The scientific arguments are well presented and the accent is inevitably on the so-called engineering ceramics which are comparatively simple ones, usually single-phase polycrystalline and low in porosity. I suspect that the industrial ceramist who is often dealing with multi-phase, inhomogeneously textured ceramics often containing appreciable porosity, may view the book critically. For example, he will not find any comment on the well established strength/porosity relationships. Neither is there any attempt to demonstrate how the knowledge developed can be used to design a ceramic. No doubt Dr Davidge takes the view that our understanding has not developed sufficiently to take such issues on board.

However, the above remarks are not meant to detract from the excellence and usefulness of this book which I am sure will be welcomed by the scientist researching into the subject.

The Concept of a Blood-Brain Barrier

by **Michael Bradbury**, *University of London.*

An authoritative treatment of the blood-brain barrier — the history of the concept, its structure, function, and applied physiology and pharmacology. The subject is dealt with in the context of the blood brain — CSF system, and the emphasis is on exchange across the cerebral capillaries and their glial processes rather than on the cerebrospinal fluid or the extracellular fluid of the brain. The barrier is treated as a cellular membrane, similar in many respects to an epithelium, being permeable to water, polar solutes, and lipid-soluble compounds, and having the capacity for facilitated and active transport.

Hunger Disease: Studies by Jewish Physicians in the Warsaw Ghetto

edited by **M. Winick**, *Columbia University College of Physicians and Surgeons.*

A translation from the Polish of a manuscript smuggled out of the Warsaw Ghetto that details studies performed by the resident Jewish physicians on patients suffering from Nazi-imposed starvation. Some of the findings were firsts in the medical literature and others remain unique today. Each chapter of the book is followed by extensive comments by the editor — bringing the information up-to-date and outlining the most recent findings in the particular area discussed. Topics include: clinical changes in adults; clinical changes in children; metabolic adaptations including carbohydrate and acid base metabolism; circulatory changes including blood volume, circulation time, pulse pressure, venous and aertial pressure, oxygen consumption, and cardiac work measurements; changes in the eye and in vision; changes in the blood and bone marrow; and pathologic anatomy. (Series: *Current Concepts in Nutrition)*

Mechanisms of Cell Change

edited by **J.D. Ebert**, *Marine Biological Laboratory, Woods Hole, Massachusetts,*
and **T. Okada**, *Kyoto University, Japan.*

An authoritative, timely, and concise volume focusing on the central problem of development, based on the essential mechanisms underlying the development of integrated multicellularity, diversified tissues, and organismic wholeness. It includes detailed coverage of recent Japanese discoveries, since Japan has emerged as one of the world's centres of research in the field. The book is based on the proceedings of the 8th International Congress of the International Society of Developmental Biologists.

0471 03097 X — $48.65/£24.60

Advances in Enzymology and Related Areas of Molecular Biology Vol. 48

edited by **A. Meister**, *Cornell University Medical College.*

The forty-eighth volume in a continuing series of outstanding reviews by authorities in enzymology and related fields. The series reviews progress made in the various branches of this expanding science and has become essential to all who wish to keep abreast of the literature. *(Advances in Enzymology Series)*

April 1979 — 462 pages
0471 04428 8 — $36.50/£18.30

Moulds, Toxins and Food

by **C. Moreau**, *Laboratoire de Biologie Végétale, Faculté des Sciences, Brest;*
translated and edited by **M.O. Moss**, *Department of Microbiology, University of Surrey.*

In this comprehensive account of fungal toxins Claude Moreau adopts a multi-disciplinary approach covering mycological, biochemical, chemical, veterinary and nutritional aspects of the subject. The book has been considerably updated since the publication of the French edition and contains an additional chapter by the translator on recent developments in the study of mycotoxins. It is well illustrated and there is an extensive list of references.

February 1979 — 492 pages
0471 99681 5 — $49.50/£21.00

Methods of Biochemical Analysis Vol. 25

edited by **D. Glick**, *Stanford Research Institute, Menlo Park, California.*

Volume 25 of this ongoing series which deals with a particular determination or group of related determinants that are of great interest and use to biochemists. It includes chemical, physical, and biological assays as well as basic techniques and instrumentation for the determination of enzymes, vitamins, hormones, lipids, carbohydrates, proteins, minerals, anti-metabolites. *(Methods of Biochemical Analysis Series)*

April 1979 — 392 pages
0471 04397 4 — $38.95/£19.65

Table of Isotopes 7th Ed.

edited by **C.M. Lederer** and **Virginia S. Shirley**, *both of Lawrence Berkeley Laboratory, University of California, Berkeley.*

An up-to-date, concise, and readily usable compilation of nuclear data for each mass number, presenting properties of the more than 2600 known isotopes, both stable and radioactive. It includes isotopic mass, natural abundance, nuclear spin, neutron capture and fission cross sections, decay modes and branchings, decay energies, half-life, certainty and means of identification, means of production, energies and intensities of all radiations, angular and polarization correlations of radiations, half-lives of excited states, and level schemes for each nucleus as determined from radioactive decay and from nuclear reactions.

April 1979 — 1632 pages
0471 01479 3 — (cloth) $53.00/£26.60

KODANSHA SCIENTIFIC BOOKS

Adaptation and Speciation in the Fall Webworm

Ed. T. Hidaka
196PP. ¥6,000

This book gives a general account of the biology and ecology of the fall webworm *(Hyphantria cunea)*, an insect pest introduced to Japan from North America at the end of World War II.
The main topics covered include larval behaviour, life cycle programming, the biological clock, mating behaviour, population dynamics, past and present adaptation and speciation. Although the emphasis is given to the present status of the species in Japan, both the point of origin of the Japanese population on the American continent and the status of the larval types found there are discussed.

The Silkworm: an important laboratory tool

Ed. Y. Tazima
320PP. ¥9,000

The economic importance of silk, especially in Japan, has prompted exhaustive research on the domesticated silkworm, *Bombyx mori*. Tremendous progress has been made with this insect during the past 50 years in several sectors of pure and applied entomology, such as developmental physiology, nutrition, endocrinology, mutation studies, and toxicological testing. This progress derives not only from the ingenuity of the researchers concerned, but also owes much to the characteristics of the silkworm as an experimental animal. That is to say, it is easy to raise, easy to deal with, of moderate body size, shows uniform growth, and is readily available in large numbers at a single developmental stage.

Molecular Basis of Enzyme Function —Lysozyme—

By. K. Hamaguchi and K. Hayashi
216PP. ¥6,000

A considerable amount of modern biochemical research is directed toward elucidating the relationship between structure and function of proteins, and of enzymes in particular. Lysozyme is one of the simplest and best-studied enzymes; its structure and that of the enzymesubstrate complex have been analyzed in detail by X-ray crystallography, and the physicochemical properties of the lysozyme molecule in solution have been studied extensively. The aim of the present book is therefore to describe the physicochemical properties and enzymic action of lysozyme in relation to its structure, with special emphasis on the authors' own work, in order to develop a better understanding of the molecular basis of enzyme function.

Practical Mass Spectrometry for the Medical and Pharmaceutical Sciences

By. A. Tatematsu, H. Miyazaki, M. Suzuki and Y. Maruyama
296PP. ¥8,000

While numerous books are available that introduce the principles and basic applications of mass spectrometry, no single book has ever covered the theme of, 'how to use mass spectrometry practically and more effectively.' In the present volume, the mass spectrometer is discussed first, followed by the interpretation of mass spectra, fragmentation patterns, and a description of computerized high resolution techniques. Three full chapters are devoted to gas chromatography-mass spectrometry, covering topics from the column packing, glass capillary-column handling and sample derivatization to mass fragmentography and mass chromatography. The final four chapters provide a novel feature in that they deal specifically with advanced techniques, including the utilization of stable isotopes in drug metabolism, the principles and applications of never ionization techniques (viz. chemical ionization and field desorption mass spectrometry), and discussion of liquid chromatography-mass spectrometry combination analysis.

Please order from your bookseller or, in case of difficulty, direct from the publisher. Orders from individuals must be accompanied by a remittance.

The first nanosecond

Chlorophyll Organization and Energy Transfer in Photosynthesis. Ciba Foundation Symposium (new series). Edited by G. Wolstenholme and D. W. Fitzsimons. (Excerpta Medica: Amsterdam, Oxford and New York, 1979.) $38.25; Dfl86.

THIS book presents the proceedings of a meeting held in February 1978, on the primary processes of photosynthesis. The events in question span the time from the moment when light is absorbed, to the first separation of electric charges. All this happens in less than a nanosecond (10^{-9}s). The subsequent processes of biochemical electron transfer were deliberately excluded from consideration in this book. Those readers who find this too restrictive might consult *Primary Processes of Photosynthesis* (*Topics in Photosynthesis*, Vol. 2, edited by J. Barber; Elsevier: Amsterdam, New York and Oxford, 1977) which takes a broader view of the primary processes, at least as far as the millisecond time scale.

The present book is principally concerned with that remarkable molecule, chlorophyll and the way in which it is arranged in the chloroplast membranes to give the properties that are required for photosynthesis. In fact chlorophyll seems to exist in several types of proteolipid complex, each having a different function. The bulk of the chlorophyll serves as antenna to capture light energy and rapidly transfer it to reaction centres. The spectroscopic work of Katz and his group has convincingly shown that each reaction centre contains a special pair of chlorophyll molecules. The next step is presumed, by analogy with the simpler systems of photosynthetic bacteria, to be the formation of a radical pair in the reaction centre. From then onwards, the rest is chemistry. The details of these processes are being investigated from various directions. The structure of the system can be investigated by electron microscopy, and by biochemical investigation of the chlorophyll-protein complexes. The dynamics of energy transfer is investigated by spectroscopic techniques; at present only optical methods are fast enough. The most spectacular is laser-pulse spectroscopy which makes it posssible to study fluorescence lifetimes of the order of 10^{-11}-10^{-10}s. 'Picosecond' has become something of a buzz-word in this field. By this means the initial processes of energy transfer are now accessible, if the results are compared with suitable chemical and/or theoretical models.

The papers are interspersed with long discussions, (which even have their own reference lists and index). These are one of the most valuable features of the book, for here the experts on these disparate methods are trying to reconcile their results to give a coherent picture. How can the chlorophyll-protein complexes extracted by Thornber, Anderson and others, be identified with the various lumps seen in the chloroplast membranes in the freeze-etch electron micrographs of Staehelin and Arntzen? How does the theory of exciton transfer allow energy to be transferred from them to the reaction centres? Perhaps there is more chlorophyll in between, and so on.

The view of the photosynthetic unit which this book takes as its starting-point is considerably more advanced than it was a few years ago. It is possible, as Sir George Porter suggests in his Chairman's introduction, that a fairly complete understanding may emerge in the next few years. We are not there yet, but the book gives an indication of the techniques by which this understanding may be achieved.

Richard Cammack

Richard Cammack is Lecturer in the Department of Plant Sciences, King's College, University of London, UK.

Electrical phenomena in polymeric materials

Electrical Properties of Polymers. By A. R. Blythe. Pp.191. (Cambridge University Press: Cambridge, 1979.) £17.50.

THIS book provides an excellent basic introduction to a wide range of electrical phenomena in polymeric materials in terms of the molecular and electronic processes involved. It brings together the well-established area of dielectric relaxation, which has contributed greatly to our understanding of molecular conformations and correlated motions in polymers, with the less well understood phenomena of conduction and electrostatic charging, each of which are assuming increasing importance because of their relevance to polymer applications.

The introductory chapter includes a brief survey of the chemical and physical structure of polymers, providing a useful background to those with limited experience of polymer science. In chapter 2 the derivations of standard relationships between the equilibrium dielectric constant and molecular dipole moment are clearly outlined. The third chapter introduces and defines the frequency-dependent dielectric constants and discusses the associated relaxation parameters and underlying molecular reorientational processes. Chapter 4 presents a comprehensive account of dielectric measurement techniques. An illuminating discussion of current knowledge and ideas regarding ionic and electronic conduction mechanisms is given in chapter 5 together with relevant sections on conducting composites and resistivity measurements and some interesting suggestions on the feasibility of obtaining materials with novel conduction properties. The two final chapters are concerned with the practically important topics of dielectric breakdown and static charge phenomena, respectively.

The book is written with care and authority and is particularly recommended to students of polymer science as an educative text on electrical behaviour. Polymer research workers, industrial manufacturers and users of plastics should also find the book a useful acquisition, bearing in mind the detailed accounts of measurement techniques, the references to further reading at the end of each chapter and relevance of electrical properties to polymer applications.

Raman effect

The Scientific Papers of C. V. Raman. Vol. 1: The Scattering of Light. Pp. 699. (Indian Academy of Sciences: P.O. Box 621, Bangalore 560 006, 1978.) £8

THE Raman effect is one of the most significant discoveries ever made in spectroscopy. Professor Sir C. V. Raman (1880–1970) was awarded the Nobel prize for physics in 1930 for his work on the scattering of light which resulted in this discovery.

Sir C. V. Raman

This clearly produced volume contains a selection of 94 of the scientific papers published by Professor Raman, either by himself or along with his students, on the subject of light scattering. It contains an historical introduction to the life and work of this "grand old man" of Indian Science by S. Ramaseshan who was responsible for selecting and editing the papers on behalf of the Indian Academy of Sciences. The collection contains papers on colloid scattering, molecular scattering, surface scattering and Brillouin scattering and also his pioneering publications on molecular anisotropy.

The monograph he wrote in 1922 on the *Molecular Diffraction of Light* and also his investigations on X-ray scattering and Compton scattering have been included, as these played a significant role in his discovery of the Raman effect in 1928. The intense interest he developed in the scattering of light was due to the visual impact the blue of the Mediterranean sea made on him on his first voyage to Europe in 1921. Even on this journey he was well prepared for experimental observations, for he carried in his pocket Nicol prisms, a small telescope to which polarisers and analysers could be attached, a slit, and even a diffraction grating. In later years he studied the scattering from pure organic materials which S.. Venkateswaran, a part-time worker in his laboratory, had succeeded in purifying by slow distillation *in vacuo*. Using filtered sunlight to irradiate these liquids in his work with K. S. Krishnan, Raman observed that all pure organic liquid showed this "feeble fluorescence" and he became convinced that this was the modified scattering of altered wavelength corresponding to the "milder fluctuations" in the state of the scattering molecule. Pointing a direct vision spectroscope on to the scattered track he saw that the scattered light contained not only the incident colour but at least another separated in wavelength from it by a dark space. Then replacing the filtered sunlight by a mercury arc he recorded sharp modified Raman lines for which the frequency shifts were identified with some of the characteristic infrared active vibrational frequencies of the molecule.

He was a man of wide interests in physics and published many papers on sound, ultrasonics, the solid and liquid state as well as optical phenomena. His physical intuitive abilities enabled him to jump several steps in mathematics and his capacity to expound complicated concepts in physics in a simple and appealing manner always made him a popular speaker. The lecture in which he announced his discovery of the Raman Effect and his Nobel lecture are included in the volume.

Sir C. V. Raman lived long enough to see the whole field of Raman spectroscopy rejuvenated and increased in importance by the use of lasers, which form ideal sources for the observation of the effect. This has enabled much of the earlier work to be repeated under conditions of greater resolution and signal to noise ratio. However, this volume reminds us of the way that Raman blazed new trails by discovering new phenomena such as shear waves in liquids and the 'soft mode' process in crystals. This book will be of value to all interested in light scattering and the Raman effect. At £8 it represents outstanding value for money as it is a bound volume of nearly 700 pages. Along with the International Raman conference held last year in Bangalore this record of his work forms a fine tribute to the achievements of this outstanding Indian scientist.

G. R. Wilkinson is Professor of Physics at King's College, University of London, UK.

Marine productivity

Marine Production Mechanisms. International Biological Programme, Vol. 20. (Edited by M. J. Dunbar. Pp. 338. (Cambridge University Press: Cambridge, 1979.) £25.

LONG before the International Biological Programme (IBP) was thought of, international collaboration was a feature of marine science and it is probably because of this that this synthesis volume from the marine productivity section does not survey the whole field but presents a number of largely unrelated chapters summarising work carried out specifically under IBP auspices. The contributions fall into two groups, regional studies of productivity and ecosystem structure, with an *entr'acte* in the form of a short chapter by Velasquez on seaweed utilisation in the Phillipines.

The regional studies span seas from the sub-Arctic — primary production in Frobisher Bay, Arctic Canada, is described by Grainger — to the tropics — primary productivity in Indian waters being reviewed by Qasim. Detailed studies of food webs in the coastal waters of Japan are described by Hogetsu, the vertical distribution of phytoplankton in the open Pacific and Atlantic oceans by Semina, and production cycles in the Dutch Wadden Sea by van der Eijk. Parsons touches on mathematical modelling in his account of the Strait of Georgia, British Columbia, but there is no extensive discussion of the potentialities of this approach. Grindley discusses productivity and upwelling in the Benguela region and Dunbar relates production in the Gulf of St Lawrence to the pattern of water circulation, but the currently fashionable topic of the relationship of production to fronts in the sea has emerged since the IBP was concluded.

The contributions on ecosystem structure are of particular interest in being all by Russian workers. Pepita gives a quantitative account of energy flow in food webs in southern seas of the USSR and the tropical Pacific. A major role in energy supply is attributed to bacterial utilization of dissolved organic matter in tropical waters both by Pepita and by Shushkina and Vinogradov in the following chapter; the contributors to the earlier chapters largely assume that the classical radiocarbon technique of Steemann Nielsen gives an adequate measure of primary production. Neyman and Yablonskaya in the two next chapters employ the useful concept of trophic groups in studies of benthic faunas, and finally Golikov and Scarlato describe the pattern of distribution of benthic faunas in the shelf seas of the USSR. All this is most interesting but few details of methods are given so that, the references being almost exclusively to papers in Russian journals, assessment of the results will be difficult for most of us.

This book will be of great value to the specialist but cannot be recommended as an introduction to the study of marine productivity.

G. E. Fogg

G. E. Fogg is Head of the Department of Marine Biology at the University College of North Wales, Bangor.

COMING SHORTLY!

Immunology Letters

for the rapid publication of short reports in Immunology

Aims and Scope
The journal will provide a vehicle for the rapid publication of short, complete and definitive reports of work in all aspects of immunology. The essential criteria for publication will be clarity, experimental soundness and novelty. Results contradictory to current accepted thinking or ideas diverging from actual dogmas will be considered for publication provided that they are based on solid experimental findings. Preference will be given to papers of immediate importance to other investigators, either by their new methodology, experimental data or new ideas. Commentaries and replies related to the published reports may also be accepted provided that they are short (maximum 700 words) and scientifically relevant to the reports mentioned, in order to provide a continuing forum for discussion.

Contents of first issue:

Biological activity of anti-brain antibodies. The effect of anti-synaptic membrane antibodies on slow and action potentials of the rat sympathetic ganglion.
by V.L. Savić, B.D. Janković and J. Horvat (Belgrade, Yugoslavia).

Ontogeny of the immuno-neuro-endocrine relationship. Early thymectomy of the chick embryo.
by B.D. Janković, K. Isaković and Z. Knežević (Belgrade, Yugoslavia).

Rapid immunofluorescent detection of a viral infection in tissue culture.
by H.H. Weetall, A.A. Luderer, H.C. Orr and P.C. Probst (Corning, N.Y. and Bethesda, Md., USA).

Anti-BSA antibodies in the repertoire of the quasi-silent ($a3^-$) variants of the rabbit V_H allotype of the a-locus,
by P. De Baetselier, R. Hamers, C. Hamers-Casterman and W. van der Loo (St-Genesivs-Rode, Belgium).

A new kind of immunosuppression associated with erythropoiesis,
by E. Conway de Macario and A.J.L. Macario (Albany, N.Y., USA).

Quantitation of neutrophil infiltration in vivo,
by A.C. Issekutz and H.Z. Movat (Toronto, Ont., Canada).

The use of polyvinyl alcohols as tolerogenic carriers for suppression of anti-hapten IgE antibody responses,
by W.Y. Lee and A.H. Sehon (Winnipeg, Canada).

Cytotoxic effect of anti-lymphocytic globulin on leukaemic myeloblasts,
by M.F. Heyworth and S.C. Truelove (Oxford, U.K.).

The effect of antibodies to mononucleotides on RNA synthesis in vitro,
by O.V. Matarova and D.M. Goldfarb (Moscow, USSR).

Cytotoxicity of an antiserum to an acidic protein present in mesodermal macrophages.
by L.I. Persson, C. Wikkelsø and L. Rönnbäck (Göteborg, Sweden).

Immunosuppressive and contraceptive effects of testosterone and cyproterone acetate in guinea pigs,
by M. Vojtíšková, M. Poláčková, V. Vicklický and Z. Pokorná (Prague, Czechoslovakia).

Natural killing of human fibroblast cell lines differing in interferon-sensitivity,
by K. Ohmon, M. Kawata, K. Okumura, T. Kuwata and T. Tada (Chiba, Japan).

Publication Schedule and Subscription Information: Volume I in 6 issues (First issue scheduled for July 1979)
Subscription Price: US $75.50/Dfl. 155.00 incuding postage.

BRITISH MUSEUM (NATURAL HISTORY)
CROMWELL ROAD
LONDON SW7 5BD

CATALOGUE OF THE OCEAN BOTTOM DEPOSITS COLLECTION IN THE BRITISH MUSEUM (NATURAL HISTORY) Part 1: Atlantic and Arctic oceans, including the European seas. (The first of two volumes).

H. A. Buckley, C. J. Elliott, Nancy M. Graham, L. R. Johnson, D. R. C. Kempe and D. B. Williams.
1979 On microfiche with introductory booklet £12.00

The Catalogue lists on microfiche the holdings of some 30,000 samples of Ocean Bottom Deposits in the Department of Mineralogy, British Museum (Natural History), consisting of surface samples, cores, manganese nodules, and dredged rocks. The Collection was founded on that of H.M.S. Challenger and contains many other interesting items. Full collection details are given for each sample: position, depth, ship, station, date, collection method, amount, and description, together with notes and references. 'Splits' of most samples are available for research purposes.

There are five fiches detailing the Collection; a sixth has the introduction and four sample distribution plots, for North and South Atlantic, Arctic Ocean, and British Isles waters. The introduction and four plots are also included in visual format. The second part of the Caalogue, covering the Indian and Pacific oceans, should be available in 1980.

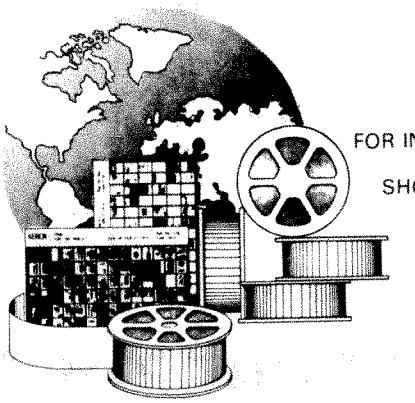
Circle No. 08 on Reader Enquiry Card.

A TEXTBOOK ON ALGAE

H D KUMAR and H N SINGH

A volume in the *Macmillan International College Editions* – low cost but authoritative books covering the history and cultures of the third world.

A general and comparative account of the structure, reproduction and life history of the most important generae of algae common in the tropics.



* A comprehensive introduction to an increasingly important field of study
* Deals with warm water algae

£7.95 hardcover 0 333 26071 6

24-28 March 1980, **Eurocon '80,** Stuttgart (Prof. Dr W.E. Proebster, IBM Deutschland GmbH, Postfach 80 08 80, Germany).

24-25 March 1980, **Radio Transmitters and Modulation Techniques,** London (The Institution of Electrical Engineers, Savoy Place, London WC2, UK).

24-28 March 1980, **Vacuum Devices,** Cambridge (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

25-27 March 1980, **Combined Municipal-Industrial Wastewater Treatment,** Dallas (Prof. A. Netzer, University of Texas at Dallas, PO Box 688, Richardson, Texas 75080).

26-28 March 1980, **Phase Transitions in Molecular Solids,** Exeter (Prof. A.J. Leadbetter, Dept of Chemistry, University of Exeter, Stocker Rd, Exeter, UK).

27-28 March 1980, **Coatings-80,** Atlantic City (Alena Enterprises of Canada, PO Box 1779, Cornwall, Ontario, Canada K6H 5V7).

Awards

Dr Donald S. Fredrickson, Director of the United States National Institutes of Health has been the awarded Gerónimo Forteza Gold Medal.

The Institute of Physics, London, and the German Physical Society have awarded the 1979 Max Born Medal and Prize to **Dr J.B. Taylor** of the Culham Laboratory, UKAEA.

The American Geophysical Union have made the following awards: **Frank Press** received the William Bowie Medal; **Syun-Ichi Akasofu** received the John Adam Fleming medal; **Edward E. Irving** received the Walter H. Bucher Medal; **Wallace S. Broecher,** received the Maurice Ewing Medal presented jointly by the United States Navy and the AGU; Three James B Macelwane Awards were conferred to **Ralph J. Circerone, Michael C. Kelly, and R. Keith O'Nions.**

The 1979 Hewlett-Packard Europhysics Prize has been awarded to a group of five physicists from several European countries: **Eric A. Ash** (University College, London); **Jeffrey H. Collins** (University of Edinburgh); **Yuri V. Gulaev** (Institute of Radio Engineering, Moscow); **Kjell A. Ingebrigtsen** (Norwegian Institute of Technology, Trondheim); **Edward G.S. Paige** (Department of Engineering Science, Oxford University).

Professor A.G. Everson Pearse (Royal Postgraduate Medical School, London), has been awarded the Ernst-Jung-Prize for Medicine 1979. Two other scientists have been awarded the Ernst-Jung-Prize, **Professor Karl Lennert** (Kiel) and **Professor Ake Senning** (Zurich).

The Council of The Institute of Physics has awarded the 1979 Holweck Medal and Prize to **Professor A. Blandin** of the Universite Paris-Sud, Orsay, for his contributions to the theory of metals.

APPOINTMENTS VACANT

UNIVERSITY
OF GENEVA
MEDICAL SCHOOL
THE DEPARTMENT
OF MORPHOLOGY
Geneva, Switzerland

invites applications for a position of

RESEARCH ASSOCIATE

in developmental biology. Candidates should be MD or PhD with experience of teaching embryology to medical students and be able to set up an active research unit in the Department. Ability to teach in French is mandatory. Salary, before income tax starts at SFr 57,000 per annum. Send complete résumé to: Dr L. Orci, Chairman, Department of Morphology, Medical School, rue Ecole de Médecine, 1211 Geneva 4, Switzerland.
W229(A)

UNIVERSITY
OF EXETER

TEMPORARY
LECTURESHIPS IN
ENGINEERING GEOLOGY

Applications are invited for a post of Temporary Lecturer in Engineering Geology. This post is tenable for one year from 1 September 1979 or as soon as possible thereafter.

Salary within the range £4,232 to £5,048 per annum (£4,333 to £5,199 per annum from 1 October 1979).

Further particulars from Miss Doreen Watson, Northcote House, The Queen's Drive, Exeter, EX4 4QJ, to whom applications (7 copies, candidates overseas 1 copy) should be sent by 30th July 1979. Please quote reference number 3217.
2527(A)

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

PHYSIOLOGY DEPARTMENT

A person is required for a new technical support post. Duties will include organising and carrying out determination of hormones by radioimmunoassay and other procedures and of metabolities by various analytical and autoanalytical methods; the developing of new assay procedures; and participating and co-operating in other departmental research.

Appointment will be as Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) according to experience. Applicants should have a degree in a relevant subject, for appointment as SO. Degree or HNC in a relevant subject with at least five years' post qualifying relevant practical experience for HSO.

Application forms are obtainable from the Secretary, NIRD, Shinfield, Reading RG2 9AT. Quote reference 79/13.
2475(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

funded by the University, in the DEPARTMENT OF FIBRE SCIENCE AND TEXTILE TECHNOLOGY

to work with Dr. J. Ferguson on the production of regenerated cellulose fibres using novel techniques. Applicants should have experience in chemistry, physics or textiles.

Appointment will be for one year in the first instance on Range 1A of the national salary structure for research and analogous staff with a commencing salary up to £5,048 per annum rising to £5,199 per annum from 1 October 1979. Placing according to qualifications and experience. Superannuation benefit. The appointment will commence on 1 September 1979, or as soon as possible thereafter.

Written applications naming two referees (quoting R27/79) should be forwarded to Dr. H. M. Elder, Department of Fibre Science and Textile Technology, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, from whom further information may be obtained.
2523(A)

The Gambia

Assistant Director
(Research and Specialist Services)
Department of Agriculture

Up to £9,975 (plus allowances)

Candidates, aged between 30 and 50, should hold a degree in Agriculture or related subject and have at least ten years' experience of agricultural research work on sub-tropical crops. They should also have some knowledge of administrative procedure in a Government Department of a developing country.

Duties will involve co-ordinating the planning and implementation of research and specialist services programmes.

Salary includes a substantial tax-free allowance paid under Britain's overseas aid programme. Basic salary attracts 25% tax-free gratuity.

Benefits include free passages, generous paid leave, children's holiday visit passages and education allowances, outfit allowance, appointment grant and interest-free car loan.

The terms on which civil and public servants may be released if selected for appointment will be subject to agreement with their present employers.

For full details and application form write quoting MD/214/NA.

Crown Agents

The Crown Agents for Oversea Governments and Administrations, Recruitment Division, 4 Millbank, London SW1P 3JD
2516(A)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF GEOPHYSICS

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the post of Postdoctoral Research Fellow to work on the analysis of regional gravity data in Britain. The project is collaborative with the Applied Geophysics Unit of the Institute of Geological Sciences and other University groups, and has the objective of preparing and interpreting a regional gravity map of Britain.

Applicants, who will need to be numerate with computing experience, should have a good background knowledge of British geology. Although based in Edinburgh, they should be prepared to spend part of their time working in collaborating institutions.

The appointment is for 2½ years with a salary of £4,776 to £5,321 pa beginning on October 1st, 1979. Applications, including a full curriculum vitae and two referees, should be made by August 13th 1979 to: Dr R. G. Hipkin, Department of Geophysics, JCMB, Mayfield Road, Edinburgh, EH9 3JZ. Please quote reference 5032.
2505(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PHYSICS

POST-DOCTORAL RESEARCH FELLOW IN RAMAN SPECTROSCOPY

Applications are invited for a post of

RESEARCH FELLOW

in the above Department to work on a project funded by the Science Research Council. The successful applicant will study the anisotropy and polarization-dependence of Raman scattering from single crystals of organic compounds whose structures are related to that of poly(ethylene terephthalate). The work will be closely linked with that of a large research group studying the properties and microstructure of polymers. The starting date for the project is 1 October 1979 and the appointment will be made for a fixed period of two years.

Starting salary in the range £4,333 to £4,910 (under review) on the 1A scale for Research and Analogous Staff (£4,333 to £7,521). The candidate will work under the direction of Dr. D. I. Bower, who will welcome preliminary enquiries about the post (Telephone: (0532) 31751 ext. 6530 or 6485).

Applications, accompanied by a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to the Registrar, The University, Leeds LS2 9JT, quoting reference number 52/9/D.
2514(A)

RESEARCH OFFICER

LABORATORY ANIMALS CENTRE

The Director's research programme is primarily concerned with an evaluation of the advantages which accrue from the use in research of specific pathogen free animals, in particular the cat. A person in the Research Officer category is required to assist the Director in this programme. Opportunities will occur for collaborative work with other departments in the Centre, which cover the whole spectrum of Laboratory animal science.
The successful applicant will have a degree or equivalent in a biological science, and at least two years relevant research experience. Salary will be related to age, qualification and experience and is supplemented by £354 London Weighting. Contributory pension scheme.
Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to The Director, MRC Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF.

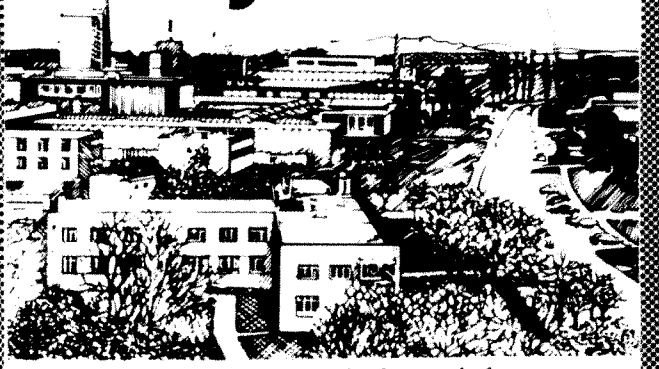
THE DEPARTMENT
OF
CLINICAL IMMUNOLOGY
has a vacancy for a
NEWLY QUALIFIED
TECHNICIAN

with relevant HNC and a sound knowledge of immunological/biochemical techniques, to work with the Senior Lecturer on problems related in particular to allergy to experimental animals.
Salary M.L.S.O. scale starting at £3,366 + £354 L.W.
Apply to the Secretary, Cardiothoracic Institute, Fulham Road, London, SW3 6HP, stating age, experience and qualifications and giving the names of two referees. 2472(A)

ENGLISH CHINA
CLAYS LTD

HEAD OF TECHNICAL
SERVICE (PRP)

English Clays Lovering Pochin & Co Ltd, the major operating Company of the English China Clays Group has a vacancy for a lively self-motivated person to head the Paint, Rubber and Plastics Section of Technical Service within Research & Development Department. The job involves managing a group of 12 people providing both a customer visiting service and the laboratory back up necessary for such a service.
Candidates should be graduates or possess an equivalent professional qualification and will have several years experience of a relevant customer technology, preferably with an emphasis on the rubber industry. Knowledge of a foreign language would be an advantage.
The position is based at the Company's well equipped laboratories at St Austell in Cornwall where facilities provided are excellent.
Competitive salary is negotiable and fringe benefits include Profit participation, pension and free life assurance; full assistance will be given with re-location expenses.
Applications, together with a curriculum vitae, quoting reference 276C to: The Company Secretary, John Keay House, St. Austell, Cornwall. 2474(A)



UNIVERSITY
OF EXETER
DEPARTMENT OF GEOGRAPHY
TECHNICIAN GRADE 3

Applications are invited for the post of:
GEOGRAPHY
TECHNICIAN
to work in the physical geography laboratories. The work involves the analysis of river water samples. Applicants should possess the Science Laboratory Technician's Part I Certificate or equivalent. Salary scale £2,931 to £3,336 pa with initial placement according to age, qualifications and experience.
Further particulars from Miss Doreen Watson, Northcote House, Queens Drive, Exeter, to whom applications should be sent by 27 July 1979. Please quote reference No. 5121. 2513(A)

UNIVERSITY
OF LIVERPOOL
BIOENGINEERING AND
MEDICAL PHYSICS UNIT
RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant/Senior Research Assistant/Research Associate to work on a research project concerned with the development of an artificial blood vessel.
The project has been running for three years and has led to a prototype vessel which is at present undergoing thorough evaluation, leading eventually to commercial exploitation.
The research assistant will be involved in the application and development of small scale production and testing apparatus, as well as being innovative in making improvements necessary for future generations of prosthesis. He/she will be expected to utilize His/her own specialities and interests in the research and development of the improved product.
The post is most suitable for someone with a degree in a related physical science, an interest in bioengineering and possibly research experience. Any queries regarding the post should be made to Mr. R. Clarke, 051-709 6022, ext. 2292.
The initial salary will be on the scale £3,689 to £5,321 pa, or £4,232 to £5,850 pa, for candidates with a PhD.
Applications, together with the names of three referees, should be received not later than 31st July, 1979 by the Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote Ref: RV/695/N. 2528(A)

Health Physicists

Science graduates are invited to apply for professional operational Health Physicist posts in the Environmental and Medical Sciences Division of the Atomic Energy Research Establishment at Harwell. The Division is responsible for provision of health protection services for the establishment, and for a broadly based research programme in this field.
Harwell is the largest research laboratory of the United Kingdom Atomic Energy Authority, and one of Europe's premier contract research laboratories. It is situated in pleasant countryside mid-way between Oxford and Newbury, approximately 10 miles from the M4 motorway.

Duties
To be responsible to a Senior Health Physicist for running an effective radiological protection and occupational hygiene service for a major area of the establishment. The job is a challenging one involving advice to staff of all grades on protection standards and procedures, and supervision of a small team. Health Physicists are required to assist in training programmes for professional and other staff.

Qualifications and experience
Applicants should possess a degree in a scientific subject. Experience of work with radioactive materials or toxic hazards would be an advantage. Necessary specialist training will be provided.

Salary
Appointments will be made in the grade of Professional and Technology Officer Grade II. Salaries, which are currently under review, are in the range £3947-£6140 a year, depending on qualifications and experience. Benefits include four weeks annual holiday, plus public and privilege holidays, superannuation and sick pay schemes.

Accommodation
Rented housing may be available for married candidates living beyond daily travelling distance, and hostel accommodation can be provided for single officers.
For an application form and further details please write to: Mr. F. G. Northeast, Personnel Department 'E' (Ref: E3981), Room 204, Building 77, Harwell, Oxon. OX11 0RA, or telephone Abingdon (0235) 24141 Ext. 2408.
2550(A)

HARWELL

Technical Officer Plant Physiologist/ Agronomist

Plant Protection Division is the focal point in the ICI Group for the research, development and marketing of crop protection chemicals on a world-wide basis.

We are looking for an experienced post-graduate to lead a small research team engaged in the discovery of products to regulate the development of crop plants. Initially the work will be concerned with monocotyledonous crops and in particular temperate cereals. This is an important position within an expanding and exciting branch of the pesticide industry.

The job holder will be responsible for organising and technically supervising glasshouse and growth room experiments to test growth regulator chemicals, and for advising on field programmes. The person we recruit will also be a member of multidisciplinary work groups within the Plant Growth Regulation project team, and integration of the work programme with that of other disciplines is an important aspect of the job.

Applicants must have a PhD or equivalent experience in a biological discipline, preferably in the field of agricultural botany or whole plant physiology, and ideally will have gained further research or industrial experience. Specialist knowledge of the physiology and agronomy of cereals, and familiarity with the crop in the field are essential. Experience of working with plant growth substances and some background knowledge of chemistry are desirable.

Jealott's Hill Research Station is situated on an attractive farm estate between Bracknell and Maidenhead. We offer a very good remuneration, and we will help with relocation expenses where appropriate.

If you are interested in this vacancy, please write or telephone for an application form to: Mr D Spence, Personnel Officer, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berks. Tel: Bracknell 24701 EXT 3350. Please quote Ref 79/PGR.

university college of swansea

Research Assistant

Applications are invited from candidates with a good honours degree in Biochemistry or a related discipline for the vacancy of **Research Assistant** in the **Department of Biochemistry**. The successful applicant will work on an SRC sponsored research programme concerned with the carbamoyl phosphate synthesis in the blue-green alga *Gloeocapsa*. This is part of a wider programme involving studies of nitrogen-fixation in blue-green algae.

The appointment will be for one year from October 1, 1979, the salary will be £3,775 per annum.

Further particulars and application forms (2 copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom they should be returned by *Friday, August 3, 1979.*

2503(A)

UNIVERSITY OF EDINBURGH

CENTRE FOR TROPICAL VETERINARY MEDICINE

LECTURER IN TROPICAL ANIMAL PRODUCTION

Applications are invited for the post of Lecturer in Tropical Animal Production. The appointment will be for two years.

The successful candidate will contribute to the M.Sc./Diploma course in Tropical Animal Production and Health run jointly by the Centre for Tropical Veterinary Medicine and the School of Agriculture.

The person appointed would become a member of staff of the Department of Tropical Animal Health. Preference will be given to graduates with experience of animal production in the tropics and specialist knowledge of an aspect of cattle production would be an advantage.

The salary offered would be in the range £3,689 to £8,452 (£3,775 to £8,992 from 1st October 1979).

Applications should be sent to the Director, Centre for Tropical Veterinary Medicine, Easter Bush, Roslin, from whom further particulars can be obtained. Closing date 16th July. Please quote reference 1065.

2405(A)

INSTITUTE OF CANCER RESEARCH: Technician required at the Sutton, Surrey, laboratories to assist research (supported by MRC) into the effect of drugs on the response of mouse tumours to X-rays. Experience not essential, but BSc, HNC or equivalent qualification a requisite. Salary in range £3,261 to £3,582 pa plus London Allowance of £354 pa (scales under review). Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref 301/B/79.

2535(A)

INSTITUTE OF CANCER RESEARCH: Technician required to assist in a project on human colon cancer at Pollards Wood Research Station, Buckinghamshire. Experience in microbiology essential. Salary in scale £3,261 to £3,471 pa (scales under review). Please write with full curriculum vitae in duplicate and the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/80.

2534(A)

UNIVERSITY OF GLASGOW

POSTGRADUATE RESEARCH ASSISTANT

A biochemist is required to carry out studies on neurochemical and behavioural aspects of lead exposure as part of a Scottish Home and Health Department funded project. The project, which will last for a minimum of three years, will be studying the influence of chronic environmental lead exposure on neuro-transmitter release and behaviour in animals together with aspects of brain morphology and function.

Salary will be on Range 1B of the salary scale for Research and Analogous Staff (£3775 - £5488) depending on age and experience. The post is superannuated.

The successful applicant will have the opportunity to register for the degree of Doctor of Philosophy in the University of Glasgow.

Applications should be made to Professor A. Goldberg, or Dr. M.R. Moore, Department of Medicine, Gardiner Institute, Western Infirmary, Glasgow, G11 6NT and accompanied by a Curriculum Vitae and the names and addresses of two referees.

In reply please quote Ref. No. 4484M.

The International Atomic Energy Agency

seeks

SENIOR GEOCHEMIST

FOR ITS LABORATORY IN MONACO

To work with biologists and other chemists on problems of the transfer of pollutants to and from marine sediments. PhD in Marine geology, geochemistry or chemistry and 10 years of appropriate experience. Initial contract two years, emoluments depending on experience US$36,922.30 tax-free. Additional allowances for dependants. Travel and removal expenses paid. Six weeks annual leave. Send curriculum vitae under Vacancy Notice No. 55/79 to IAEA, Division of Personnel, PO Box 590, A1011 Vienna, Austria. W220(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY

Scientific Programmer

Applications are invited for two posts in the Instrumentation Division to develop new algorithms and large portable computer programmes for mathematical and statistical analysis. Applicants should have extensive experience in writing and documenting user-oriented programmes. A background in handling large amounts of data and in areas like image processing, X-ray diffraction, system identification or large-scale linear and nonlinear programming would be helpful. A degree in numerical analysis or computer science is preferred, but a physicist or engineer with the above qualifications would also be considered.

The salary offered will be between DM3,500 and DM4,500 monthly, depending on qualifications and experience. Certain allowances are payable in addition, depending on personal circumstances.

The closing date for applications is 15 September 1979.

Please write briefly, quoting reference 79/14, with a curriculum vitae and the names of referees to:

Sir John Kendrew, Director General, EMBL, Postfach 10.2209, D-6900 Heidelberg, Germany. W214(A)

WELSH NATIONAL SCHOOL OF MEDICINE

(University of Wales)

DEPARTMENT OF HAEMATOLOGY

pplications are invited from science aduates for the post of RESEARCH FFICER in the above Department at eath Park, Cardiff. The person ppointed will take part in the investigation iron chelating agents of potential eraputic use and will be actively involved iron balance studies using animal odels. The appointment is for a three year riod. Salary on the scales for University esearch and Analogous Staff, starting lary dependent upon qualifications and perience but could be up to £4505 per num.

Applications in the form of a brief rriculum vitae with the names and dresses of two referees and quoting ref. o. H24/2/34 should be sent to the gister and Secretary, Welsh National hool of Medicine, Heath Park, Cardiff, 4 4XN, three weeks from the date of pearance of this advertisement. Further ormation available from Professor A. obs, Department of Haematology 22/755944 ext. 2375). 2492(A)

THE UNIVERSITY OF LANCASTER

CHAIR IN ENVIRONMENTAL SCIENCES

Applications are invited from scientists for appointment to a Chair in Environmental Sciences. The department currently has 19 full time academic staff. Its interests include a wide range of scientific subjects grouped into the four sections: Geological and Surface Water Processes, Atmospheric Processes, Solid Earth Sciences and Planetary Sciences. The department offers honours degrees in Environmental Sciences and contributes half of the content in each of the honours degrees in Ecology and in Geophysical Sciences. There are good workshop facilities and well equipped laboratories for research and teaching. The appointee will replace Professor A N Hunter as Head of the Department for a minimum period of five years.

Further particulars may be obtained (quoting reference L152/D) from the Establishment Officer, University House, Lancaster, LA1 4YW to whom applications (9 copies) naming three referees, should be sent not later than 31 August 1979.

2540(A)

CSIRO AUSTRALIA

Impending vacancies for Divisional Chiefs

Institute of Biological Resources

CSIRO, Australia's largest research organization with some 7,000 staff has recently grouped its research divisions into five institutes.

The objectives of the Institute of Biological Resources are to expand knowledge and understanding of Australia's biological resources and to discover and develop better methods for the management and use of its crops and pastures, forests and wildlife of both land sea with the aims of improving the efficiency and reliability of primary production while preserving and enhancing the desirable features of the Australian environments.

The Institute consists of eight divisions with a total staff of about 1,640 of whome some 600 are professional.

During 1980 and 1981, the position of Chief of the Divisions of Fisheries and Oceanography, Forest Research, Entomology and Wildlife Research within the Institute will become vacant owing to retirements. The positions will be advertised some months hence. But in the meantime, preliminary expressions of interest are invited, and **CSIRO** would be pleased to provide information on the work of the Divisions.

A Chief of the Division is responsible for the leadership, development, scientific direction and integration of the research programs of the Division, and is encouraged to promote active collaboration with other divisions, industry and research bodies working in associated areas.

Appointment to the organization is for an indefinite period and carries commonwealth superannuation privileges subject to normal conditions. The position of Chief is offered for a negotiable term of the order of seven years, with subsequent options for a further term, if mutually desired, or a senior position in the organization. Salaries are subject to negotiation, and currently are not less than $ A 34,374 p.a. (Chief, level 2).

As a brief introduction, the Division of Fisheries and Oceanography is based at Cronulla (Sydney, NSW) with other centres in Queensland and Western Australia. The Division of Forest Research is based at Canberra (ACT) with stations in Victoria, Queensland, South Australia, Western Australia and Tasmania. The Division of Entomology, based in Canberra, has centres in NSW, Queensland, Western Australia and Tasmania, and several overseas research groups. The Division of Wildlife Research based in Canberra has centres in the northern territory and Western Australia. Copies of the annual reports of the divisions are available from CSIRO Head Office and from the Australian Scientific Liaison Offices in London and Washington.

Mr. M.V. Tracy, Director of the Institute, would be pleased to discuss the position with potential applicants. He would also be pleased to receive advice concerning these appointments from people with a particular interest in them but who do not wish to be considered as applicants. He can be contacted at:

CSIRO, Head Office, P.O. Box 225, Dickson ACT 2602, Australia.

Mr. Tracy expects to visit the United Kingdom and USA in the next 12 months, and would be pleased to have discussions concerning the appointments with potential applicants and other interested parties.

2545(A)

EUROPEAN JOURNAL OF BIOCHEMISTRY

Applications are invited from graduates in biochemistry, PhD preferably, for the post of

EDITORIAL SECRETARY

at the journal's office in Liège.

Salary will be around £5,800 net per annum, or more according to special experience. Applicants should preferably be nationals of the member states of the European Economic Community.

Applications, which should include the name of at least one referee and complete curriculum vitae, should be sent as soon as possible to Professor Claude Liébecq, 69/054 Boulevard de la Constitution, B-4020 Liège, Belgium.

2533(A)

PROBLEM SOLVING MARKETEER
Physiological Measurements
(Excellent Salary + Car + Expenses)

Nicolet Instruments Limited is the United Kingdom subsidiary of the Nicolet Instrument Corporation of Madison, Wisconsin, who are manufacturers of Physiological Measurement Systems for clinical and research applications. The enormous success of these products in the United States has led to plans to expand this business into the United Kingdom.

The job of the problem solver will be to increase the sales of our medical division products by visiting medical establishments throughout the United Kingdom discussing physiological measurement problems and proposing solutions. The problem solver will also organise demonstrations, meetings and exhibitions, write editorials, advertise and generally ensure the success and growth of this business.

The person we are looking for will be a creative physiological measurements practitioner with a broad knowledge of measurement techniques including evoked responses, histogramming, signal averaging, EEG analysis, have the ability to relate equipment features to problem solutions, have a pleasant personality and a creative approach.

We believe these qualities are likely to be found in a keen physiological measurements expert working in neurology, audiology, opthalmology, medical physics or a related field, who wish to develop their career in a commercial environment. Product training will be given to the successful candidate in the United Kingdom and the United States of America.

This senior position will carry an excellent salary, company car and expenses.

FOR FURTHER DETAILS PLEASE CONTACT:
The Managing Director, Nicolet Instruments Ltd., Budbrooke Road, WARWICK. CV34 5XH or telephone: WARWICK (0926) 44111.

PHARMACOLOGISTS IN BASIC RESEARCH

We are seeking for our department of Dermatology a senior and a junior pharmacologist to join our group engaged in the study of skin pharmacology.

The successful candidates will have working knowledge of the analytical technics used in molecular pharmacology as well as experience in the detection and isolation of pharmacological mediators.

In addition, the candidates will be familiar with and have an interest in developing *in vitro* and *in vivo* animal model systems.

The senior appointment requires 8 years of post doctoral research experience and ability to motivate and direct research team, and a knowledge in skin pharmacology would be advantageous.

The junior appointee will have a minimum of 3 years of post doctoral research experience and ability to work independently.

The newly created Institute, based near Nice in the South of France, is engaged in basic research into the structure and function of the skin and its disorders.

For further information, please send curriculum vitae to:

e candidate should be a young graduate th Mathematics and Physics alifications and some teaching perience, preferably in developing untries. Editorial experience would be vantageous but not essential.

ter a period of training and assessment, candidate will be expected to deal with ir own projects through all stages of ing and production so a responsible, lligent and highly meticulous attitude he work is essential.

ase apply in writing to Sheilagh Browne, sonnel Manager, 4 Little Essex Street. ndon WC2R 3LF. 2519(A)

MACMILLAN EDUCATION

PROGRAMME DIRECTOR

SYNCHROTRON RADIATION

A dedicated source of synchrotron radiation based on a 2GeV electron storage ring is under construction at Daresbury Laboratory and is scheduled to come into operation during 1980. The design allows for up to twelve beam ports which could provide for up to about fifty experimental stations. A wide ranging scientific programme in physics, chemistry, biology and materials science is envisaged involving universities and other research institutes from all over the United Kingdom and Europe.

Applications are invited for the post of Programme Director of this new facility.

The Programme Director will be responsible to the Laboratory Director for the implementation of the scientific programme on the Synchrotron Radiation Source in accordance with the decisions of the Facility Committee which advises the Council's Science Board on the usage of the new Source and gives approval to experiment proposals. The work will cover the organisation and administration of the experimental programme and the provision of equipment and facilities required to support it in collaboration with the user groups. There is an associated programme of theoretical research, and close liaison with the Theory Group is essential.

The existing group of scientific and supporting staff for this activity will be expanded to cover a wider range of science and the experimental programme will also be supported by staff from other divisions of the Laboratory. The appointee will be expected to be an active collaborator in the research being undertaken on the facility.

The successful candidate will be a scientist with an established reputation in any area of research relevant to the use of synchrotron radiation, the administrative ability to co-ordinate a complex operation and the personality to secure the effective co-operation of the users and the staff of the Laboratory.

The post will be permanent. Alternatively, the Council will consider secondment from, or a joint appointment with, the candidate's own establishment.

The salary will be within the range of Deputy Chief Scientific Officer £13,359 – £15,116 (with a further increase in April 1980).

Applicants of either sex, should write no later than 31st July 1979 giving details of qualifications and experience to:

The Director
DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

2500(A)

UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of LECTURER IN PLANT ECOLOGY in the DEPARTMENT OF PLANT SCIENCE. Salary range: £4232 - £8452 p.a. Appointment to be made at lower end of scale. Duties to commence 1st October 1979.

Application (2 copies) together with the names and addresses of two referees should be forwarded to the Vice-Principal (Administration) and Registrar, University College P.O. Box 78, Cardiff CF1 1XL, from whome further particulars will be available. Closing date 31st August 1979. Reference 1848. 2491(A)

THE SALMON RESEARCH TRUST OF IRELAND INC.
BIOLOGIST

Applications are invited from persons with at least a good 2nd Class Honours in Zoology or equivalent qualifications for posts of Biologists at the Trust's installations near Newport, Co. Mayo. Starting salary not less than £4,000 rising to £6,450. Accommodation provided. Full details from The Secretary, St. James's Gate, Dublin 8. (Tel. Dublin 753645). Closing date for applications, 15 August. 2544(A)

POSTDOCTORAL POSITION

available to study transcription of cloned *drosophila* tRNA genes in *e. coli* and in vitro using RNA polymerase III. Project includes extensive collaboration with other laboratories at University of British Columbia working on gene expression, *drosophila* genetics and chromosome structure. Experience with nucleic acids and nucleic acid enzymes desirable. Apply with curriculum vitae to: Dr G.B. Spiegelman, Department of Microbiology, University of British Columbia, 2075 Wesbrook Mall, Vancouver, British Columbia, Canada V6T 1W5 W228(A)

COMPUTATIONAL SCIENTIST IN PROTEIN CRYSTALLOGRAPHY

The Daresbury Laboratory has a vacancy for a computational scientist in protein crystallography to develop a comprehensive suite of protein crystallography programs and to investigate new computational techniques. The post will be based in the Computational Science Group at Daresbury but will involve close collaboration with the university groups.

Applicants should possess a PhD or equivalent experience, in the field of protein crystallography and will be expected to spend some of their time on a research project.

An IBM 370/165 and a Cray 1 computer are installed at the laboratory and access is available to the IBM 360/195s at the SRC Rutherford Laboratory. The laboratory also provides a purpose-built synchrotron radiation source for the universities which will be used by protein crystallographers.

Appointments will be made at salaries (under review) between £3695 and £6216 depending on age, ability and experience. Posts are normally available for a fixed term of 3 years and are superannuable.

Closing date: 3rd August 1979

For further information please write to or telephone Pella Machin Tel No. (0925) 65000 Ext. 528.

Applications should be sent together with curriculum vitae and the addresses of two referees, quoting reference number DL/690/T to

(University of London)
Post-Doctoral Research Associate

Applications are invited for a 3-year appointment supported by the Science Research Council, to work on adhesion and locomotion of tissue cells. Candidates should possess a PhD degree, or expect to obtain one this year. Salary £4,857 per annum, rising to £5,340 per annum, (inc London Allowance).

Applications, including curriculum vitae and the names of two referees to Dr. David Gingell, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB. 2482(A)

INSTITUTE OF CANCER RESEARCH in association with the Royal Marsden Hospital, Sutton, Surrey, require Junior Technician in the Department of Histopathology. Applicants should have a minimum of 5 'O' levels including Maths, English and two science subjects or (preferably) two science 'A' levels or ONC in Medical Laboratory Sciences. Training will be given in all aspects of histological technique and Day-release will be granted. Salary in scale £2,037 to £3,015 p.a. depending on age and qualifications (scales under review), plus London Allowance of £354 p.a. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London, SW7 3NU, quoting ref. 301/B/75. 2498(A)

COMMONWEALTH AGRICULTURAL BUREAUX

POST OF DIRECTOR

COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS

Cambridge, UK

This vacancy arises from the retirement o Dr. R.H. Richens, Director of the Burea since 1964.

The main work of the Bureau is to collec and disseminate to research worker throughout the world information on th genetics, cytology and breeding o agricultural crops. This is done principall through the publication of *Plant Breedin Abstracts*, which comprises some twelv thousand abstracts per year, summarizin papers in over thirty languages. Like a others in the CAB series, *Plant Breedin Abstracts* is replicated in machine-readabl form and is accessible online through th DIALOG system.

The Director is responsible fo maintaining the high scientific standard c the journal and for the day-to-da management of the Bureau (nine scientif staff with clerical support).

Applicants should have appropriat scientific qualifications and detaile knowledge of plant breeding in bot temperate and tropical countries Experience in scientific editing is essenti and administrative competence is als required. Some knowledge of foreig languages and the linguistic problem involved in scientific information work desirable.

The scale for the post is £6609 to £846 with merit awards to £9450 (subject t revision). The starting salary will relate t qualifications and experience. The post pensionable.

The normal retiring age is 60, but th may be extended to 65.

Application forms and full particular can be obtained from the Executiv Director, Commonwealth Agricultur Bureaux, Farnham House, Farnha Royal, Slough SL2 3BN. Closing date: 3 August 1979. 2511(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the post of

RESEARCH FELLOW

in the

DEPARTMENT OF ZOOLOGY
Gegaga Institute of Tropical Endocrinology.

Appointee should have a PhD in Anim Biology (preferably fish) and is expected work on a variety of aspects of Biolo Endocrinology, Physiology a Hybridization of cichlid fish Tilapia wit view to improving tropical pond cultu Salary Scale: Research Fellow K£2,016 3,312 pa (K£1 = £1.24 sterling). The Brit Government may supplement salary range of £4,278 to 4,818 pa (sterling) f married appointee or £2,730 to 3,156 (sterling) for single appointee (review annually and normally free from tax) a provide children's education allowan and holiday visit passages. Fam passages; non-contributory medi scheme; FSSU or SSSF; subsidiz housing/housing allowance.

Detailed applications (2 copies) w curriculum vitae and naming 3 referees be sent direct to Registrar (Recruitm and Training) University of Nairobi, P Box 30197, Nairobi, Kenya by 8 Aug 1979. Applicants resident in the UK sho also send one copy to Inter Univers Council, 90/91 Tottenham Court Ro London, W1P 0DT. Further details may obtained from either address. 2481(A

UNIVERSITY OF SYDNEY

LECTURESHIP IN GEOGRAPHY

Specialist in Coastal Zone Resources and Management required for Coastal Studies Unit, which is incorporated in the inter-departmental Marine Studies Centre. Appointee will be required to participate in undergraduate and postgraduate teaching and research. He/she should have a substantial background in economic, political and social aspects of land use management and have demonstrated ability to work with decision making bodies. He/she must also have sufficient expertise in coastal morphology and dynamics to work with the Coastal Studies Unit on comprehensive projects concerned with aspects such as beach erosion and longshore and onshore sediment transport. Preference may be given to applicants with experience of the Australian coast although applications from outside Australia welcome. A PhD or equivalent in postgraduate experience required.

The position is expected to be filled by a probationary appointment of three years, capable of leading to tenure, but if all the University's requirements for tenure are deemed to be satisfactorily met tenure may be granted at the time of appointment.

Salary range: $A15,786 — $20,737 p.a.

Applications including curriculum vitae, list of publications and names of three referees by *31 August 1979* to the Registrar, University of Sydney, NSW 2006, Australia, from whom further information available. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. 2509(A)

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL
(University of London)
West Smithfield,
London, EC1A 7BE

DEPARTMENT OF HAEMATOLOGY

GRADUATE RESEARCH ASSISTANT

Applications are invited from graduates in Biological Sciences to work on a project investigating the control of erythropoiesis. An interest in immunology and/or differentation would be an advantage. The project is funded by a Wellcome Trust for three years under the supervision of Dr. T.A. Horton.

The post is tenable from October 1st 1979, and the salary will be in the Research Assistant Range 1B.

Applications, with the names of two referees and curriculum vitae should be sent not later than 27th July 1979 to the Secretary of the Medical College at the above address, quoting reference 843. 2549(A)

TWO MEDICAL LABORATORY SCIENTIFIC OFFICERS

required in the Jerry Lewis Muscle Research Centre, Hammersmith Hospital to participate in research projects on neuromuscular disorders.

a) To work on electron microscopy of muscle. Previous EM experience preferable.

b) To carry out tissue culture of human tissues. Previous experience of tissue culture preferable.

Both posts on MLSO scale of £3,621 to £4,680 per annum plus £354 London Allowance. Initially according to age and experience.

Applications with names and addresses of two referees to Professor V Dubowitz, Department of Paediatrics, Hammersmith Hospital, Du Cane Road, London W12 0HS. 2524(A)

ICI Pharmaceuticals Division Alderley Park

have vacancies for:

Graduate Pharmacologist

To work in Central Nervous System Research. The successful applicant will join a research team engaged in the search for novel psychotropic drugs, in particular drugs which may be of use in the treatment of schizophrenia.

Post graduate experience in neuropharmacology and a capacity for independent work will be an advantage. Ref: DB 4.

Experimental Toxicologist

To work in our Safety of Medicines Department. The successful applicant will supervise a small team of laboratory staff and will be responsible for the running of short term and long term toxicity studies in rodents, lagomorphs and marmosets from the receipt of protocol to the writing of the final report.

Applicants must be Home Office licensees with a wide range of experience of toxicology on rodents or lagomorphs. Experience with marmosets and other primates would also be desirable. Applicants must also have had experience in managing work groups, with a minimum amount of supervision and be used to working to the highest standards of G.L.P. Education to H.N.D. level is also desirable. Ref: DB 5.

The Division's research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Conditions of service, salary and assistance given to married staff in moving house are designed to attract and retain staff of high calibre.

Applicants, male or female, should write quoting the appropriate reference number to:

Mrs D Bass, Assistant Personnel Officer, ICI Pharmaceuticals Division, Mereside Research Laboratories, Alderley Park, Macclesfield, Cheshire. 2499(A)

UNIVERSITY OF REGINA
(Canada)

ASSISTANT PROFESSOR DEVELOPMENTAL BIOLOGY

Applications are invited from candidates who have training and experience in the biology of development at the molecular, cellular and organismic level. Expertise in plant development and regeneration from somatic cells is desirable, but not essential. Applicants must have at least two years of postdoctoral experience.

The appointee will share in the teaching of undergraduate and graduate students and is expected to develop an active research programme. Minimum salary: $18,829. Starting date: as soon as possible.

Applications including a curriculum vitae, list of publications, a statement of research interests, and the names of at least three referees should be sent to Dr. H. Bertrand, Department of Biology, University of Regina, Regina, Saskatchewan S4S 0A2, Canada before August 20, 1979. W207A

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF PHYSICS

Applications are invited for the one-year post of Postdoctoral

RESEARCH ASSISTANT

in a team studying molecular collision process by high speed pulsed microwave spectroscopy. Initial salary range pa: £4,232 to £5,850 (£4,333 to £6,066 from October 1st) according to age, experience and qualifications. Superannuation.

Applications should be sent as soon as possible to Dr. M. A. H. McCausland, Department of Physics, Schuster Laboratory, The University, Manchester M13 9PL, from whom further details are available. 2479(A)

The New South Wales Institute of Technology
Sydney, Australia
SCHOOL OF LIFE SCIENCES

Principal Lecturer and Head
Department of Biochemistry

The New South Wales Institute of Technology is a corporate tertiary institution, established to provide a wide range of professional courses for those entering or already employed in industry, Government, and technological fields.

The School of Life Sciences occupies a six-storey building at Gore Hill adjacent to the Royal North Shore Hospital. There are well equipped laboratories for teaching and research in biochemistry, pathology, microbiology, environmental biology, physical biology and general biology. The School also jointly operates the Gore Hill Research Laboratories and an Electron Microscopy Unit with the Royal North Shore Hospital.

The appointee will be responsible to the Head of School for the teaching and development of undergraduate and postgraduate programs in biochemistry. This will include the continuing development of a postgraduate course in clinical biochemistry.

It is anticipated that the appointee will possess substantial post-graduate qualifications and have relevant teaching and administrative experience. A professional interest in clinical biochemistry or biochemistry related to industrial applications would be an advantage.

The President of the Institute, Dr. R.L. Werner, will be available in London for preliminary interviews from 10-20 September, inclusive.

Further information on the Institute and conditions of employment may also be obtained from Miss Challoner, at the address below.

Conditions and method of application.

The position carries a salary of $A 26,644 per annum.

Fares and a contribution toward removal and initial accommodation expenses will be provided for an overseas appointee. A housing loan scheme is also available. With consent of Council, academic staff are permitted to undertake limited consulting work.

Applications close on 24th August, 1979. Applicants should arrange for three confidential referees' reports to arrive by the same date. Applications should include: address, telephone number, personal details, experience, qualifications, affiliations, publications, research work conducted, and the names and addresses of those referees contacted. Applications and referees' reports are to be sent to:-

The Official Secretary, N.S.W. Government Offices, 66 Strand, London, WC2N 5LZ. Telephone: 01-839 6651. 2547(A)

ASSOCIATE DIRECTOR

EISCAT Scientific Association

The position of Associate Director for Scientific Programmes with the European Incoherent Scatter (EISCAT) Scientific Association will become vacant on 1 January, 1980, and must be filled as soon as possible after that date.

EISCAT is an organisation set up by scientific research bodies in six European countries. The UK partner is the Science Research Council. The purpose of the organization is to construct and operate a research facility in Northern Scandinavia for the purpose of conducting research related to the auroral ionosphere by means of incoherent scatter radar technique.

The person appointed will be required to work at the headquarters in Kiruna, Sweden. He/she must direct the scientific activity which will include reviewing proposals for experiments from scientists within the member countries and aid in the implementation of these experiments. He/she must also help organize cooperative experiments with groups conducting related research with other types of instruments, and be responsible for the operation of the observing stations in Kiruna and in Sodankyla, Finland, in close cooperation with the Associate Director responsible for the station in Tromso, Norway.

Applications are invited from persons with several years of experience in ionospheric and magnetospheric research. In addition to research experience administrative ability is desirable. Good knowledge of or experience in several of the following fields is required:

The physics of the troposphere, mesosphere, ionosphere and the magnetosphere;

Plasma physcis;

Measurement techniques, particularly involving the application of radio waves for diagnostic purposes;

Radar techniques and technology;

Digital computers, real time and off-line processing.

The appointment in Sweden will be for a two-year period. Remuneration and benefits will be in accordance with qualifications and experience; the terms and conditions of appointment will be negotiable.

Applications by letter, including a full c.v., should be sent by no later than 17 August to:

Mr. A. CHALLIS, SCIENCE RESEARCH COUNCIL, P.O. Box 18, SWINDON, WILTS., SN2 1ET.

2542(A)

BIOLOGICAL CHEMISTRY POLYSACCHARIDES

Applications are invited for posts of Scientist and Technician in a section of the Research and Development unit of Weddel Pharmaceuticals Ltd, a subsidiary of the Union International Company Ltd. The section is part of the Chemical Services Department at the Union International Research Centre, St. Albans and is engaged in investigation of complex carbohydrates for medicinal uses.

THE SCIENTIST will require a good honours degree in Biochemistry or Chemistry and an interest in the isolation and characterisation of natural polymers. Some industrial experience would be advantageous but not essential.

THE TECHNICIAN should be qualified to about HNC standard in science and have an aptitude for careful experimental work. Training in specific techniques will be given.

The laboratories are pleasantly situated and within easy reach of St. Albans city centre.

Applications please in writing, giving full career details to:

J. E. Dawes (AD 6093),
Weddel Pharmaceuticals Ltd.,
14 West Smithfield,
London,
EC1A 9JN

2480(A)

SCOTTISH UNIVERSITIES RESEARCH AND REACTOR CENTRF

1. REACTOR HEALTH PHYSICIST

2. RESEARCH FELLOW IN NUCLEAR MEDICINE

Applications are invited for the above posts which are at present temporary although there is a possibility of the first becoming permanent in the future. In both cases candidates should possess an honours degree in a physical science and have a knowledge of radioactivity and nuclear techniques. For the first post experience in health physics is necessary and for both some expertise in nuclear medicine, radiochemistry or a related topic is desirable. Successful candidates will be expected to pursue research in collaboration with Scottish University Departments. Applications including curriculum vitae and the names of two referees should be sent to the Director, Professor H. W. Wilson, Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow, G75 0QU, not later than 3rd August 1979.

Salaries: Post 1: £4,232 to £8,452 pa (Lecturer Scale)
Post 2: £3,689 to £7,145 pa

University Superannuation Scheme. 2507(A)

UNIVERSITY OF NAIROBI — KENYA

Applications are invited for the post of LECTURER IN CLIMATOLOGY — DEPARTMENT OF GEOGRAPHY. Applicants should possess Ph.D. qualifications in Geography (with climatology as their principal areas of specialization). Interest in the studies of arid zones may be an advantage but not a condition. Applicants should also demonstrate interest in high level research evidenced by publications.

Besides the teaching of climatology at both undergraduate and postgraduate levels, the appointee should be able to participate in the teaching of at least two other areas of Geography. Salary scale: Lecturer K£2016 - 3312 pa (K£1 = £1.24 sterling). Family passages; FSSU or SSSF; non-contributory medical scheme; subsidized housing/housing allowance. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Registrar (Recruitment and Training), University of Nairobi, P O Box 30197, Nairobi, Kenya by 8 August 1979. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further details may be obtained from either address. 2484(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)
DENMARK HILL, LONDON, SE5 8RX.

LIVER UNIT

Applications are invited for the post of POSTDOCTORAL SCIENTIFIC RESEARCH FELLOW

to join a multidisciplinary team investigating factors governing susceptibility to alcoholic liver disease. The successful applicant would be responsible for setting up tissue typing in the Liver Unit in collaboration with Professor R. Batchelor at the Hammersmith Hospital, and some previous experience in immunological techniques is essential.

Salary on the scale for Research and Analogous Staff Grade 1A (up to £7145 + London Weighting).

For further details, contact Dr. Roger Williams, Director of the Liver Unit at the above address.

Applications to the Secretary of the Medical School by 3rd August 1979.

2459(A)

INSTITUTE OF CANCER RESEARCH: Technician required at the Chester Beatty Research Institute, Fulham Road, London, SW3, to join a research team to work on the development of new chemotherapeutic agents for use in cancer. Cytotoxic drugs will be covalently linked to antibodies raised against tumour cells in order to target the drug specifically to the malignant tissues in the mammalian body. Candidates should possess an HNC, university degree or equivalent qualification in pharmacology, microbiology, biochemistry or other relevant subject. Experience in tissue culture methods would be an advantage. The post is available immediately and is tenable until July, 1983. Starting salary will be in accordance with MRC scales in range £3,261 to £4,293 p.a. (under review) plus London Allowance of £354 p.a. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/78. 2478(A)

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London)

LABORATORY SCIENTIFIC OFFICER

Required in a research laboratory a technical assistant in a team with Professo Holborow investigating immunologic aspects of rheumatic and other disease The vacancy is suitable for someon interested in training in immunoenzym methods. Salary range (currently und review) £3,615/£4,284 including Londo Weighting, according to qualification The post is available from 1st September

Applications as soon as possible t Professor E. J. Holborow, Bone and Joi Research Unit, The London Hospit Medical College, Turner Street, Londo E1 2AD, quoting reference n BJRU/7/79. 2476(A)

ANGLO-AUSTRALIAN OBSERVATORY

Research Astronomers

The Anglo-Australian Observatory comprises the 3.9 metre telescope near Coonabarabran, NSW, and a laboratory at Epping near Sydney, Australia. There is a scientific staff of six astronomers nominated by the United Kingdom and Australia. Three of these positions become vacant prior to October 1980.

Candidates should have a strong background in physics or astrophysics. Appointments will be fixed terms of 1 to 5 years, with salaries in the range A15,422 to A30,530 per year, plus other allowances, fares, etc in addition.

The successful applicants will have the choice of being based at the laboratory or the telescope. They will provide assistance to visiting astronomers, and also contribute to the development, maintenance and general running of the AAT and its instrumentation. In addition they will have opportunities for personal research and collaboration with Australian and UK astronomers.

Applications should include:

1. Age, citizenship, country of residence and marital status.
2. Qualifications and experience, including date of PhD.
3. Astronomical research projects for which telescope time will be sought. Sufficient information is required to show the proposals would be competitive in applications to a time assignment committee.
4. Any instrument development project in which the applicant is particularly interested.
5. When applicant would be available.
6. Length of appointment envisaged.
7. Names and addresses of three referees.

Enquiries and applications should be addressed to:
Mr A Challis, Manpower Section, Science Research Council, PO Box 18, North Star Avenue, Swindon, Wiltshire SN2 1ET by 31 July 1979.

The three references should also be addressed to Mr Challis.

2510(A)

UNIVERSITY OF SUSSEX

SCHOOL OF MOLECULAR SCIENCES

POSTDOCTORAL RESEARCH ASSISTANT

pplications are invited for a position as a ostdoctoral research assistant to work ith Professor C. Eaborn on synthetic and echanistic aspects of the chemistry of erically-hindered organosilicon mpounds. The appointment will be for 1 ar starting from October 1979, and the arting salary will be in the range 232-£5591 p.a. Applications, including rriculum vitae and the names and dresses of two referees, should be sent as on as possible to Professor C. Eaborn, hool of Molecular Sciences, University Sussex, Brighton BN1 9QJ. 2501(A)

UNIVERSITY OF NOTTINGHAM QUEEN'S MEDICAL CENTRE

TECHNICIAN

DEPARTMENT OF BIOCHEMISTRY

pplications, male or female, are invited r the position of Technician in the epartment of Biochemistry. The ccessful candidate will be required to rk on the study of cell free protein nthesis in bacteria. Applicants should be aduates or hold HNC/HND or uivalent qualifications. Salary range 261 to £4,680 per annum depending on age and qualifications.

Application forms from: Mr F. C. eeby, Chief Technical Adviser, Medical hool, Queen's Medical Centre, ttingham. Closing date 27th July, 1979. 2512(A)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF ANIMAL PHYSIOLOGY
Babraham, Cambridge, CB2 4AT

Two vacancies exist at the Institute of Animal Physiology, Animal Research Station, Cambridge, at Senior Scientific Officer level.

CELL BIOLOGIST/ DEVELOPMENTAL BIOLOGIST

interested in working on basic problems of the development and differentiation of the early mammalian embryo. The person appointed will be expected to pursue independent studies on some aspect of the egg during preimplantation development. Experience in cell fusion, membrane biology or nuclear-cytoplasmic interactions would be an advantage. Ref. TR7.

BIOCHEMIST/ MOLECULAR BIOLOGIST

with an interest in applying modern biochemical techniques to the study of the mammalian egg during early development. Preference will be given to applicants who will be willing to pursue independent studies on some aspect of oocyte maturation, fertilization or preimplantation differentiation. Experience in protein synthesis or gene expression would be an advantage. (Ref MFH6).

Candidates should possess a first or upper second class honours degree together with at least four years relevant post-graduate experience, with preferably a PhD degree and a good record of published work. Salary in scale, which is under review, £5,154 to £6,898 pa. Non-contributory pension scheme. Application forms and further details may be obtained from the Secretary of the Institute. Please quote reference number. Closing date for applications 6th August 1979. 2515(A)

EUROPEAN TRAINING PROGRAMME in BRAIN AND BEHAVIOUR RESEARCH

TRAINEESHIPS

Traineeships of three, six or rarely nine months are offered to promising young scientists working in the area of brain and behaviour research in order to broaden their skills and knowledge in a field other than but related to their own. The grants are given to allow them to learn a particular technique abroad for which training is not offered in their own country. The trainee is expected to return to her/his original post upon termination of her/his training so that her/his institute will in turn be able to benefit from newly acquired skills.

All applications have to be accompanied by a letter of recommendation by the sending institute and by a letter of acceptance from the receiving institute. Preference is given to post-docs under the age of 35.

TRAVEL GRANTS

Travel grants are awarded to allow young research workers to visit another laboratory in connection with an on-going research project or to participate in international meetings and symposia. In addition special grants are to be awarded to students to enable them to take part in the yearly meetings of the European Neuroscience Association (ENA) which this year will take place in Rome on September 10-14.

Applications should be accompanied by letters of recommendation from the sending institute and of invitation from the institute to be visited. Applicants should be postgraduate research workers with the exception of applications to attend the yearly ENA meeting. In this particular case preference is given to postgraduate students.

The deadline for completed applications is *March 15 and September 15*. Further information and application forms may be obtained from:

INTERNATIONAL LABORATORY FOR RESEARCH ON ANIMAL DISEASES (ILRAD)
Nairobi, Kenya

IMMUNOLOGIST TO WORK ON PARASITIC DISEASES

There are in the laboratory of the Director of ILRAD two vacancies for immunologists to work on theileriosis. The research will include the infection and transformation of bovine lymphocytes and other cell types by theileria parasites and analysis of cell-mediated immune responses to the parasites and parasitized cells.

Applicants should have experience of cellular immunology and of parasitic or other infectious diseases.

Salary will depend on age and experience. Perquisites include moving allowance, housing and commutation allowances, medical and retirement benefits.

Applications, with *curriculum vitae*, list of publications and the names of three referees, should be submitted to the Director, ILRAD, PO Box 30709, Nairobi, Kenya by 12th August 1979. W203(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF ONCOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

A postdoctoral research assistant is required, for a period of 3 years, to work on an MRC funded project. This will study the late effects of X-irradiation on the response of normal tissues to chemotherapeutic drugs. Applicants should have experience either in mammalian radiobiology, or in the study of cell kinetics in vivo.

Starting salary, according to age and experience, up to £5,034, inclusive of London Allowance. Applications, together with a curriculum vitae and the names of 2 referees should be addressed to Dr. E. Hamilton, Department of Oncology, The Middlesex Hospital Medical School, London W1P 7PN. 2517(A)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICS

COSMIC RAY RESEARCH

Applications are invited for three posts of RESEARCH ASSISTANT, each of 24 months duration, for work within the cosmic ray studies group under Professor P.H. Fowler, FRS. These posts will be concerned with experiments to measure the high energy component of the ultra-heavy cosmic rays and the "anomalous" component of the low energy cosmic rays.

Experience with nuclear or spacecraft instrumentation, especially the use of drift chambers and microprocessor based data acquisition systems, would be appropriate.

Salaries will be on the scales for research staff grades 1A (2 posts) £4232 x £273 and 1B (1 post) £3689 x £272.

Applications should be made by 3rd August to Dr. R.M. Redfern, H.H. Wills Physics Laboratory, Tyndall Avenue, Bristol BS8 1TL. Telephone: Bristol 24161 ext. 110. 2506(A)

UNIVERSITY OF WARWICK

RESEARCH TECHNICIANS

The Department of Biological Sciences has vacancies in its four Research Groups, namely Chloroplast development, Developmental Biology (Molecular Genetics), Microbiology and Virology. The posts involve working under the direction of a senior scientist on a specific research project using the modern experimental techniques and instrumentation of molecular biology. The posts are for contract periods of one to three years and are available from October, 1979. Applications are invited from graduates and others with appropriate qualifications in biochemistry and/or microbiology. Salary either on Technician Grade 2B scale £2,759 to £3,138 p.a., or Grade 3 scale £2,931 to £3,336 p.a. Applications by letter giving full details of qualifications, experience etc to the Personnel Office, University of Warwick, Coventry CV4 7AL, quoting Ref. No: 47/D/79 by 20th July, 1979. 2396(A)

UNIVERSITY OF THE WEST INDIES
Trinidad

Applications are invited for the post of:

TEMPORARY LECTURER

AGRICULTURAL ENGINEERING
DEPARTMENT OF CROP SCIENCE

for two years. Specialization in soil and water management or mechanization of crop production is desirable. Salary scale 1977/78 (under review) TT$19,071 to 29,799 pa (£1 sterling = TT$5.18). Family passages; FSSU; unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 20% of pensionable salary; study and travel grant. Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent direct to Secretary, UWI, St Augustine, Trinidad as soon as possible. Applicants resident in the UK should also send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 2538(A)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF BIOCHEMISTRY
SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES

GRADUATE RESEARCH ASSISTANT

Applications are invited for a MRC funded graduate research assistant to work with Dr C R Lowe on the development of specific electrode systems for proteins, carbohydrates and steroids of clinical importance. Applicants should have a good Honours Degree in Biochemistry or Chemistry.

The appointment is for one year in the first instance, with the possibility of renewal for a further two years. The salary will be £3,775 pa on scale 1B for Research and Analogous Staff; USS benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton, SO9 5NH by 30 July 1979, quoting reference 1085/R/N. 2495(A)

UNIVERSITY OF EAST ANGLIA

Norwich

RESEARCH IN ENVIRONMENTAL CHEMISTRY

Applications are invited for the position of Senior Research Associate on a project to investigate the chemistry of the air-sea interface, more especially the measurement of natural volatile organo-metallic compounds in surface waters with a view to evaluating their role in the global cycling of trace metals. The post is suitable for someone with a first degree training in chemistry and relevant postgraduate experience in chemistry or oceanographic/atmospheric services. The appointment is for two years on the salary scale £4232 — £7145 per annum plus USS.

Further information is available from Dr. P.S. Liss, School of Environmental Sciences, University of East Anglia, Norwich NR4 7TJ, to whom applications, including the names of two referees, should be sent as soon as possible. 2502(A)

UNIVERSITY OF LIVERPOOL

TWO TECHNICIANS (Grade 2B)

DEPARTMENT OF BIOCHEMISTRY

To assist groups studying (a) The biosynthesis and metabolism of sterols in higher plants and algae. (b) Hormonal control of insect development. Minimum qualification ONC or equivalent relevant qualifications. Minimum experience of 3 years.

The posts are tenable for 2½ years with possibility of renewal.

Salary within a range of £2757 — £3138 p.a., according to qualifications and experience.

Application forms may be obtained from The Registrar, The University, P.O Box 147, Liverpool, L69 3BX. Quote ref RV/686. 2468(A)

THE FACULTY OF MEDICINE Memorial University of Newfoundland requires a RESEARCH SCIENTIST who will be a staff member. The successful candidate must have considerable research experience involving messenger ribonucleoprotein complexes and translational control of protein synthesis in euckaryotic cells. In addition, the successful candidate must have graduate with a Ph.D. Degree from an approved college or university with major course work in Biochemistry or Molecular Biology. The incumbent will be primarily involved in conducting a research program in the characterization of the messenger ribonucleoprotein complex of euckaryotic cells. Current emphasis is on the role of these complexes in translational control of protein synthesis during myogenesis. Duties will also include responsibility for supervising research projects on the regulation of protein synthesizing machinery in both euckaryotic and prokaryotic cells. The salary for the position will be at the rate of $16,254.00 per annum. Applications or enquiries should be forwarded, not later than July 31, 1979 to Dr. Bruce Sells, Professor, Laboratories of Molecular Biology, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada. W221(A)

SUB-EDITOR

required to work on POLYMER, the international journal for the science and technology of polymers, within an expanding group of scientific research journals based in Guildford. Minimum qualification: first degree or equivalent, preferably in chemistry or the physical sciences; preference will be given to candidates with experience in sub-editing, proof-reading and handling scientific texts from edited version to publication. Good salary and career opportunities. Salary £3,880 + L.V.'s and reading allowance.

MRC NEUROCHEMICAL PHARMACOLOGY UNIT

MRC Non-clinical Scientific Staff

A vacancy exists on the Scientific staff of the Unit for a NEUROPHYSIOLOGIST to undertake research on the actions of drugs and neurotransmitters at the single cell level in mammalian CNS. The Unit's research programme focuses particularly on the mode of action of anti-psychotic and other psychoactive drugs, and studies of neuropeptides.

A well equipped neurophysiology laboratory with computer facilities is available, and candidates should have several years postdoctoral experience in this or a related field of research.

Salary depending on age and experience, is expected to be within the range £5048 (-£6627) or £6886 (-£8452) but an appointment at a more senior level is not excluded. MRC Conditions of service, including superannuation.

Contact: Dr L Iversen, Director, MRC Neurochemical Pharmacology Unit, Department of Pharmacology, Medical School, Hills Road, Cambridge, CB2 2QD. 2486(A)

UNIVERSITY OF WARWICK

SENIOR RESEARCH TECHNICIAN

Required in the Department of Biological Sciences to organise the daily running of the technical services of a Virology Research Group and to assist with research under the personal direction of Professor D.C. Burke. The research is aimed at cloning of the interferon gene in bacteria.

Applications are invited from suitably qualified persons with several years experience of biochemistry and preferably tissue culture. Salary on the Technician Grade 5 scale: £3474 to £4056 p.a. The post is available initially for 12 months with the probability of extension for a further 5 years.

Applications in writing giving full details of age, experience etc., to the Personnel Office, University of Warwick, Coventry CV4 7AL quoting Ref. No: 48/3D/79, as soon as possible. 2487(A)

INSTITUTE OF CHILD HEALTH

SENIOR MEDICAL LABORATORY SCIENTIFIC OFFICER OR MEDICAL LABORATORY

SCIENTIFIC OFFICER

Applications are invited for the single post of SMLSO or MLSO to take part in a 4 year, Leukaemia Research Fund supported research project examining the molecular basis for the synthesis of onco-fetal proteins (particularly-feto protein) in human tumours. Experience with DNA and/or RNA extraction and assay a major advantage. Tissue culture experience also helpful.

The grading of the post (SMLSO or MLSO) would depend on the experience and qualifications of the successful applicant. SMLSO salary scale is £4347 to £4769; MLSO scale is £3366 to £4680 plus London Weighting.

Applications, accompanied by full curriculum vitae and addresses of two referees, to: Dr. J. Pritchard, Department of Haematology and Oncology, The Hospital for Sick Children, Great Ormond Street, London, WC1N 3JH. Enquiries about the post to Dr. Pritchard on 01-405 6200 Ext. 248. Closing date for applications 25 July 1979. 2548(A)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF PHYSICS

Applications are invited for the post of

LECTURER

in the Department of Physics. The successful candidate will be expected to carry out experimental work within the Atomic, Molecular and Polymer Physics Group of the Department. Some preference will be given to candidates intending to pursue studies in the fields of coherent interactions or laser spectroscopy, but candidates having other interests which are related to those of the Group will also be considered. The appointment is from October 1st, 1979 or as soon as possible thereafter at an initial salary normally within the range £4,333 to £5,199 p.a. Further particulars and application forms are obtainable from the Registrar, the University, Manchester M13 9PL, to whom completed forms should be returned by August 3rd. Quote ref: 147/79/N. 2526(A)

UNIVERSITY OF BRISTOL

SCHOOL OF CHEMISTRY, ORGANIC GEOCHEMISTRY UNIT

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant (Grade 1B) to assist in the application and development of computerised gas chromatography-mass spectrometry and related techniques to the analysis of organic compounds in sediments and petroleums. Instrumentation includes Finnigan 4000, MS 30 and CH-7 spectrometers interfaced to an INCOS 2300 data system. Applicants should have a qualification in chemistry or physics and an interest in instrumentation. Previous experience in mass spectrometry and/or gas chromatography would be an advantage.

This post is funded by the Natural Environment Research Council (starting salary £3689 - £4232 per annum).

Please send applications with details and the names of two referees to Professor G. Eglinton, University of Bristol, School of Chemistry, Cantock's Close, Bristol BS8 1TS. 2490(A)

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Applications are invited for a three-year POSTDOCTORAL appointment to work with Dr D.G. Smyth in the Laboratory of Peptide Chemistry, available from October 1st 1979. The position will be filled by a candidate with interest and preferably experience in the field of neuroactive peptides, with particular emphasis on the study of processing enzymes and control mechanisms. Some training in the techniques of protein chemistry or membrane biochemistry would be an asset.

The appointment will be in the salary range £4940 - £6627 per annum according to age and qualifications plus £502 p.a. London Allowance; superannuation provision.

Applications, giving details of qualifications, experience and the names of two referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA before 31st August 1979, quoting reference PC/1. 2485(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF THERAPEUTICS AND CLINICAL PHARMACOLOGY

Applications are invited for the post of

TEMPORARY LECTURER

(non-medical) in Therapeutics and Clinical Pharmacology. The appointment will be for a period of three years. The duties will be to undertake pharmacokinetic studies in collaboration with the medical and scientific staff of the Department. An interest and experience in measuring the drug content of biological fluids by chromatographic or enzymatic methods will be an advantage.

Salary in the range £4,333 to £8,992 (from 1 October) plus superannuation. Further details may be obtained from Professor O. L. Wade, The Department of Therapeutics and Clinical Pharmacology, The Medical School, Birmingham B15 2TJ (Tel: 021 472 1301 Ext 3201).

Applications, naming three referees, should be sent by 10 August 1979 to the Assistant Registrar, The Medical School, Birmingham B15 2TJ. 2521(A)

UNIVERSITY OF GLASGOW

POSTDOCTORAL RESEARCH ASSISTANT

PROTEIN CHEMISTRY/ VISION RESEARCH

Applications are invited for a Postdoctoral Research Assistant for an M.R.C. funded project on the isolation and characterization of specific visual pigment proteins. The post is available from 1st September, 1979 for a period of 14 months. Salary will be on Range 1A (Research and Analogous Staff) up to a maximum of £6627 (interim), depending on age and qualifications.

Experience in membrane proteins and/or protein chemistry essential.

Please submit applications, including resume, publications and names and addresses of at least two academic referees to: Dr. Alan Cooper, Department of Chemistry, University of Glasgow, Glasgow, G12 8QQ (Tel. 041-339-8855, ext. 7278).

In reply please quote Ref. No. 4483M. 2466(A)

STUDENTSHIPS

Athrofa Gogledd-dd Cymru
The North E Wales Institute
of higher education

KELSTERTON COLLEGE, CONNAH'S QUAY, DEESIDE, CLWYD

SRC CASE STUDENTSHIPS

Applications are invited for two SRC CASE Studentships, tenable from 1st October, 1979 for work on the following projects:

1. "Mechanism of lipid oxidation in aqueous emulsions", in collaboration with Unigate Ltd. Supervisor: Dr. J. C. Allen.
2. "Radioimmunoassay of polyamines", in collaboration with Ortho Diagnostics, Ltd. Supervisors: Drs. J. C. Allen and C. J. Smith.

The co-operating bodies will supplement the SRC Studentships by £250 p.a. Applicants should possess or expect to obtain 1st or upper 2nd class Honours, and should write as soon as possible, with curriculum vitae, to the Institute Registrar, North E Wales Institute, Kelsterton College, Connah's Quay, Deeside, Clwyd. CH5 4BR. 2426(F)

AGRICULTURAL RESEARCH COUNCIL

POSTGRADUATE STUDENSHIPS

(Standard Telecommunication Laboratories Limited)

Applications are invited from students interested in research designed to develop new methods for preventing trace element deficiency diseases in cattle and sheep.

Applicants should have a physiological background and experience of radioisotopic and stable balance methods and will be required to register for a higher degree, usually at the University of Reading.

Candidates should have a 1st or Upper Second class honours degree in a relevant subject.

The Institute is situated in a pleasant rural area with a staff restaurant and good recreational facilities. If required, accommodation for a single person could be provided in the Institute's hostel.

Non-contributory pension scheme.

Application forms from: Secretary, Institute for Research on Animal Diseases, Compton, Nr. Newbury, Berks. RG16 0NN. Quoting ref. 400. 2460(F)

UNIVERSITY OF GLASGOW

DEPARTMENT OF FORENSIC MEDICINE AND SCIENCE

N.E.R.C. RESEARCH STUDENTSHIP

Applications are invited from persons who hold or expect to hold a first or upper second class honours degree in chemistry, environmental sciences or a related discipline for a research studentship, commencing 1/10/79, funded by the Natural Environment Research Council.

The research, leading to the degree of Ph.D., will be on the topic "Environmental Geochemistry of Trace Metal Pollutants in the Urban Area of Glasgow". Analytical techniques available include AAS, FAAS, NAA, EDXRF and GLC.

Applications, including a curriculum vitae and the names of two referees, should be sent immediately to Dr. J.G. Farmer, Department of Forensic Medicine and Science, University of Glasgow, Glasgow G12 8QQ, Scotland.

In reply please quote Ref.No.4479M. 2467(F)

FELLOWSHIPS and STUDENTSHIPS continued

Commonwealth of Australia

QUEEN ELIZABETH II FELLOWSHIPS

Physical & Biological Sciences

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships scheme. Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proven capacity for original work. These are post-doctorate awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS: Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a Ph.D., or equivalent qualifications, in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine). Awards will, in general be restricted to applicants who are not more than 30 years of age on the date when applications close. Applications will also be considered from candidates for the Ph.D. degree if their thesis has been submitted for examination.

STIPEND: $17 131 (Australian) per annum – increased to $18 403 per annum at age of 28 years.

ALLOWANCES: Are payable in respect of a Fellow's dependent spouse ($500 p.a.) each dependent child ($200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses.

APPLICATIONS: *Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen Elizabeth Fellowships Committee, Department of Science and the Environment, P.O. Box 449, Woden A.C.T. 2606, Australia; the Minister (Scientific), Canberra House, 10-16 Maltravers Street, London WC2R 3EH, U.K.; or the Australian Embassy, 1601 Massachusetts Avenue, Washington D.C. 20036, U.S.A. Applications for the next round of awards, which will be announced in December 1979 close at the Canberra address on 24 August 1979.*

2469(E)

UNIVERSITY OF DUBLIN
Trinity College

UNIVERSITY OF DUBLIN
TRINITY COLLEGE
and
ST. PATRICK'S COLLEGE, MAYNOOTH
POST — DOCTORAL FELLOWSHIPS IN CHEMISTRY

Applications are invited for two positions supported by the National Board for Science and Technology.

One of these, with Professor D.R. Lloyd (Trinity College) and Professor C.M. Quinn (St. Patrick's College, Maynooth), is for work on photoemission from adsorbates. Experimental work will be carried out at Trinity College, using an angle-dispersive spectrometer. Previous experience with ultra-high vacuum work is highly desirable, and familiarity with some of the experimental and theoretical techniques of surface science would be advantageous. This fellowship is available from 1st October 1979 for one year initially, with extensions possible up to a total of three years, at a salary of £3837-3994-4153 P.A. (presently under review).

The other fellowship is for work with Dr. J.M. Kelly and Dr. D.H. Grayson, both at Trinity College, on the synthesis and properties of polymer-bound coordination compounds, and porphyrins. In order to assess their potential as solar energy converters. Previous experience with polymers, coordination compounds, heterocyclic compounds or in photo-chemistry would be helpful.

Intending applicants should contact the Establishment Officer, Trinity College, telephone Dublin 772941, extension 1775, in the first instance. Enquiries may also be made by telex 5442 TCD E1. The closing date for receipt of completed applications will be Friday, 17th August 1979.

2470(E)

UNIVERSITY OF KENT AT CANTERBURY

POST-DOCTORAL FELLOWSHIP IN MICROPROCESSOR CONTROL OF FERMENTATION

Applications are invited for a post-doctoral research fellowship in connection with a project involving the application of microprocessors to the continuous culture of micro-organisms. The successful candidate would be expected to study culture optimisation and strain selection using an apparatus consisting of a microprocessor interfaced with various monitoring and control devices attached to a fermenter. The appointment is for one year and is available immediately. Candidates should have a good honours degree in microbiology, biochemistry, bio-engineering or a related subject and post-graduate experience in an allied area. Previous experience with computer applications and programming would be an advantage.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom completed applications should be submitted by 10 August, 1979. Please quote Ref: A40/79. 2518(E)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES

RESEARCH FELLOW
RESEARCH ASSISTANT

Applications are invited for the above posts, which are funded by the SRC, in an established research group concerned with gamete recognition systems in algae. Both appointments are available for a fixed period of up to three years.

The Research Fellowship is suitable for candidates who already hold, or who expect to be awarded a PhD degree, preferably in the area of cell surface biochemistry (plants or animals) although candidates with experience in other areas will be considered. The successful applicant will be involved in the isolation and characterisation of fertilization receptors from the surfaces of algal gametes.

The Research Assistantship is suitable for a recent graduate in a biological subject. The successful applicant will be expected to work closely with other members of the group and will be particularly responsible for the development of cytochemical aspects of the project.

Starting salary at an appropriate point on the IB scale (£3,775 to £5,488) (Research Assistant) or the IA scale (£4,333 to £7,521 (Research Fellow) for Research and Analogous Staff according to age qualifications and experience. Both scales are under review with effect from 1 October 1979.

Informal enquiries about the posts will be welcomed and may be made through Drs J A Callow or L V Evans (Tel: 0532 31751 ext. 6580 or 6576).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 53/11. Closing date for applications 25 August 1979. 2522(E)

Southampton THE UNIVERSITY

APPLIED ELECTROCHEMISTRY and ELECTROCHEMICAL ENGINEERING

A number of Studentships are available within the Chemistry Department for postgraduate research on topics in applied electrochemistry and electrochemical engineering in the fields of organosynthesis, metal recovery and pollution control. Successful candidates will be expected to register for a higher degree.

Suitably qualified scientists and engineers should apply to Dr R E W Jansson, Director, Wolfson Centre for Electrochemical Science, Chemistry Department, The University, Southampton SO9 5NH, sending a curriculum vitae and the names of two referees. Please quote Ref N.

2463(F)

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY

POSTGRADUATE STUDENTSHIP IN BIOCHEMISTRY

Applications are invited for a three-year studentship available from October 1979. Candidates should have a good degree in biochemistry or related subject and the successful candidate will be expected to register for a PhD in the above Department. The project, supported by Action Research for the Crippled Child, involves the use of cell culture studies in the study of homocystinuria, a genetic defect of methionine metabolism in man. The research methodology involved in the project will be multidisciplinary.

Applications, together with the names and addresses of two referees, should be sent to Dr R. Griffiths, Department of Biochemistry, University of St Andrews, North Street, St Andrews, Fife, Scotland, as soon as possible. 2529(F)

CHEMISTRY DEPARTMENT UNIVERSITY OF OTTAWA

Post-Doctoral Research Fellowship in Electrochemistry

Applications are invited internationally for an industrially sponsored Post-Doctoral Fellowship in the electrochemistry of specialized battery and energy storage systems. Candidates should have a recent PhD in electrochemical surface studies, electrode process work or materials science. The stipend will be $16,000 pa plus some assistance with moving expenses where appropriate.

Applications, with two letters of recommendation, are to be sent to Professor B E Conway, Chemistry Department, University of Ottawa, Ottawa, Canada. W217(E)

UNIVERSITY OF ALBERTA

BIOCHEMISTRY DEPARTMENT

POST-DOCTORAL FELLOWSHIP

Apply to Dr A. R. Morgan, Biochemistry Department, University of Alberta, Edmonton, Alberta, T6G 2H7 Canada. Candidates must be knowledgeable in physico-chemical and metabolic aspects of DNA. The two main areas in which the successful candidate would have a choice of doing research would be multi-stranded nucleic acids and their possible biological roles (nucleoids, chromosome condensation, tertiary structures) and DNA replication. The position is available immediately.

W213(E)

Redland Technology Limited

(in association with Kings College London and Surrey University)

NERC and SRC CASE Studentships

Redland Technology is a member of Redland Limited, the multi-national group of Companies which is principally concerned with the manufacture of building and construction materials.

Applications are invited for two CASE Studentships for research into the mechanism of colour development on firing clay building products. One Studentship is at Kings College London University and will study the mineralogy of the clay material. The other Studentship is at the University of Surrey and will study the properties and structure of the fired materials.

Both the successful applicants will spend two months each year at the Redland Technology Laboratories at Horsham in West Sussex and additional payment will be made for this activity.

Applicants should have a good Honours Degree in Ceramics/Mineralogy/Geology/Chemistry/Physics or other appropriate discipline.

Further information can be obtained from:

Dr. G. W. Aston, Redland Technology Limited, Graylands, Horsham, Sussex. Tel: 0403 2351

2461(F)

Redland Technology

THE HARTLEY FELLOWSHIPS of the UNIVERSITY OF SOUTHAMPTON

Applications are invited for three Fellowships normally tenable from 1 October 1980, for up to two years research, in any field for which facilities are available within the Faculties of Arts, Science, Engineering & Applied Science, Social Sciences, Law, Education, Medicine and Mathematical Studies.

Fellows will normally be appointed from persons of high promise whose records show evidence of capacity for original research, and who have up to five years post-doctoral experience or equivalent research record.

Salary will be related to age and experience and be within nationally agreed ranges for research staff in universities. (No provision for travel or removal expenses).

The closing date for applications for the 1980 competition is 1 November 1979.

Details and application forms from Mr E.D. Gordon, The University, Southampton SO9 5NH.

Please quote reference N. 2462(E)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSICS

— RESEARCH STUDENTSHIP

LUMINESCENCE IN AMORPHOUS SEMICONDUCTORS

Applications are invited from men and women for an SRC CASE Research Studentship in collaboration with Dr. P.J. Dean, Royal Signals and Radar Establishment, Malvern, leading to the degree of Ph.D. The investigation will be concerned with electroluminescence and deep traps in amorphous semiconductors, within our established group studying laser excited luminescence in these materials.

Current work includes picosecond pulse exitation for time resolved studies. The programme will give experience in fundamental solid state physics and in electro-optical techniques, and presents an opportunity to study novel materials of current technological interest. The award will be subject to the usual SRC conditions with about £500 p.a. supplement by the RSRE. Applications (with the names of two referees) or enquiries to Dr. I.G. Austin/Dr. T.M. Searle, Department of Physics, The University, Sheffield S3 7RH. Tel. 78555 ext. 4288 or 4289. Quote ref: R 338(G. 2465(F)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH FELLOWSHIP IN BIOENERGETICS

Applications are invited for a Research Fellowship to investigate the factors controlling the synthesis of ATP after short flash excitation of membranes isolated from the photosynthetic bacteria. The principle aim of this SRC-supported project is to determine the relationship between electron transport reactions through defined segments of the electron transport chain, the development of the electrochemical proton gradient and the extent and rate of ATP synthesis after single and multiple flashes.

The appointment is for three years commencing October 1979 (or as soon as possible thereafter) in the range (under review) £4,333 to £5,488 (from 1 October). Starting salary not expected to exceed £4,910 pa. Candidates should preferably have some previous experience in the field of mitochondrial, chloroplast or bacterial bioenergetics.

Applications, including a short curriculum vitae and the names of three academic referees should be sent by 10 August to Miss L. R. Heyes, Senate Registry, University of Birmingham, PO Box 363, Birmingham B15 2TT. Further details may be obtained from Dr. J. B. Jackson, Department of Biochemistry. Tel: 021-472 1301 Ext. 3113.

2520(E)

Southampton THE UNIVERSITY

POST GRADUATE STUDENTSHIPS IN CRYOGENICS

Applications are invited from science and engineering graduates for one year. MSc and 2/3 year MPhil/PhD studentships in Cryogenics. Telephone Dr R G Scurlock, Southampton 559122 Ext. 2112/2068. 2464(F)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMISTRY

Applications are invited from men and women for an SRC CASE Studentship: academic investigator: Dr. A.J. Smith; co-investigator: Dr. D. Brown, Chemistry Division, Harwell. Subject: "Very High Co-ordination Numbers in Actinide Compounds". The work will involve preparative chemistry and crystal structure analysis (with the appropriate computing) of compounds of (i) uranium and thorium and (ii) the α-active elements protactinium, neptunium, and/or plutonium. Training will be given in radiochemical and crystallographic techniques; previous experience in these fields is not essential. First or Upper Second degree required.

Details from, and applications to, Dr. A.J. Smith, Department of Chemistry, The University, Sheffield S3 7HF as soon as possible. Quote ref: R 339/G 2508(F)

UNIVERSITY OF SOUTHAMPTON

STUDENTSHIP IN BIOCHEMICAL PHARMACOLOGY

Applications are invited from graduates for a research studentship on the usual MRC/Research Council terms, to study the mechanisms by which environmental chemicals may cause cancer of the gastrointestinal tract.

Candidates should have a first or upper second class honours degree in Pharmacology, Biochemistry or a related subject and will be expected to register for an MPhil with possibility of transfer to PhD. The studentship will be tenable from October 1979.

Applications with curriculum vitae and names of two referees to Dr A. G. Renwick, Pharmacology, Medical & Biological Sciences Building, Bassett Crescent East, Southampton, SO9 3TU. 2496(F)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London)

MEDICAL RESEARCH COUNCIL STUDENTSHIP

Applications are invited from a candidate with a good honours degree to work on biophysical aspects of cell-substratum interactions or membrane fusion.

Applications, including curriculum vitae, and the names of two referees, to Dr. David Gingell, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB. 2483(F)

THE CITY UNIVERSITY

DEPARTMENT OF CHEMISTRY

Applications are invited for Research Studentships tenable from 1st October 1979 and leading to a higher degree in physical chemistry.

Awards include (A) SRC CASE Studentship for work on the influence of organic sulphur compounds on hydrocarbon combustion (Professor C.F. Cullis, in collaboration with Esso Petroleum Company) (b) SRC CTA Studentship for work on organosilicon compounds as fuel additives (Professor C.F. Cullis, in collaboration with Dow-Corning) (c) SRC CASE Studentship for work on ion-exchange and detergency using zeolites (Dr. R. P. Townsend, in collaboration with Unilever Research) (d) SRC CASE Studentship for work on novel oxidation reactions of hydrocarbons in zeolites (Drs. R. P. Townsend and S. A. Matlin in collaboration with Johnson-Matthey) (e) Studentship for work on the emission of particulates during combustion processes and their interaction with other combustion products. Applications should be sent to Professor C. F. Cullis, Department of Chemistry, The City University, Northampton Square, London EC1V 0HB (Tel: 01-253 4399 Ext. 367) as soon as possible. 2532(F)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications are invited for a three-year MRC-financed research fellowship. Salary will be on the RF IA scale £4,333 to £7,521 (to operate from 1st October 1979) plus superannuation. Starting salary will be up to £5,488 according to age and previous (not necessarily related) postdoctoral experience.

The project is to study the chemical changes in virus-infected cells both *in vitro* and *in vivo* by X-ray microanalysis of frozen, freeze-dried unstained sections of cells. Observed changes will be correlated with virus-induced changes in patterns of polypeptide synthesis analysed by conventional techniques. The work will be carried out in two laboratories under the supervision of Dr. J. Stephen (Department of Microbiology, Birmingham University) and Dr. T. A. Appleton (Department of Physiology, Cambridge University). Full provision has been made for travel between the two institutions and stays of short duration in Cambridge.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, P O Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees, should be sent by Friday 27 July, 1979. Please quote ref NM6. 2397(E)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE

RESEARCH STUDENTSHIP

Applications are invited from graduates with a good honours degree for a Southampton and Wessex Medical School Trust Research Studentship tenable for three years from 1 October 1979. Successful applicants will be offered the opportunity to study for the degree of PhD, on an ongoing project investigating biochemical and immunological properties of hepatitis B virus.

Further details may be obtained from Professor Ralph Wright, Department of Medicine, Level F, Centre Block, Southampton General Hospital, Tremona Road, Southampton, SO9 4XY, telephone Southampton 777222, ext. 4299. Applications required by 23 July 1979. 2497(F)

ASSISTANTSHIPS

Centre for Applied Microbiology & Research, Porton Down
Diagnostic Reagents Laboratory

Post-Graduate Research Assistantship

A graduate research assistant with at least a 2nd Class Hons. Degree is required to investigate the use of triazine chromophores in protein and enzyme purification, immobilisation, assay and structural analysis. The successful candidate will be expected to register for a PhD. The post is funded by a research contract and is tenable for up to 3 years.

Salary will be in the range £2991-4275 (under review). NHS terms & conditions of service.

This post may be discussed informally by contacting Dr. A. Atkinson, Director, Diagnostic Reagents Laboratory. Tel. 0980-610391, Ext. 406/365.

Applications, including curriculum vitae and two academic referees should be sent to Mrs M. Bushby, Personnel Officer, CAMR, Porton Down, Salisbury, Wilts. Closing date 27 July 1979.

PHLS Public Health Laboratory Service Board. 2489(P)

UNIVERSITY OF EXETER

NERC RESEARCH ASSISTANTSHIP

Applications are invited for the post of Research Assistant in the Department of Biological Sciences. The post is tenable for two years, commencing as soon as possible. The successful applicant will work under the supervision of Mr I J Linn on a project which will involve the use of miniature radio transmitters and a semi-automated data capture system to study the range, movements and social systems of short-tailed voles *Microtus agrestis* in the field.

The minimum qualification is a good Honours degree in Zoology, Biology or Ecology; an interest in or qualification in computing and/or electronics will be an advantage.

Salary will be on the Research Assistant scale: £3689 rising to £3961 p.a. (under review). The post is superannuable.

Further particulars may be obtained from Miss Doreen Watson, Northcote House, The Queen's Drive, Exeter, to whom applications (3 copies) should be sent by 3 August 1979. Please quote reference No.7163. 2504(P)

LKB 4400
Speed and Sensitivity with Style

24 DEC 1979

Using the latest technology to provide eye-catching design, solid-state heating for the horizontal analytical column and a high temperature reaction coil for fast colour development, the LKB 4400 Amino Acid Analyser is capable of performing fast analyses on small sample volumes at the picomole level. Indeed a complete protein hydrolysate analysis, including regeneration and equilibration is carried out in only 65 minutes. Physiological fluid analysis takes less than 4½ hours.

With its built-in 70 sample autoloader and optional data handling accessory, the 4400 Analyser can fully automate your chromatographic separation.

The British family Wilj announce two talented new members

Gamma Counter 2001-S

* 50mm Crystal, 50mm shielding
* Multiple-channel facilities (SMIC)
* Additional user variable window
* Digital display directly in KeV
* Accepts alternative external counting heads
* Incorporates our unique easy to calibrate system

RIA Data-Processor 2701

* Easy to use — it asks you the questions
* Dual-channel
* Choice of curve fits: Polylinear, Logit/log & Spline
* Statistical checks

These two new additions increase Wilj's long lead on other lower-cost RIA equipment. This combination can count and process **double-isotope kits** in one simple operation.
Higher energy isotopes can be counted with the larger crystal and increased shielding.

Data-processing is no problem with Wilj peripheral options. Teletypes, paper tape, data-logger and the Hewlett-Packard 9815A programmable calculator and software can all be accommodated.

Whichever combination you choose, all Wilj products come complete with an unconditional 2 year guarantee. (U.K. Only)

wilj **SYSTEM 2001**

PROVEN RELIABILITY, VALUE AND PERFORMANCE

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a* is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Animal Marking

Recognition Marking of Animals in Research

Edited by BERNARD STONEHOUSE

* The edited proceedings of a symposium sponsored by the R.S.P.C.A.
* Includes the most up-to-date methods covering a wide range of animals from Molluscs to Elephants.
* The concern of the 27 contributors is to promote sensible, practical and above all humane methods of marking.
* Royalties from this volume are dedicated to the R.S.P.C.A.

Dec. 1978, £10.00, 0 333 23584 3

Carter's energy message

President Carter has emerged from his self-imposed period of isolation to announce a six-point plan for cutting dependence on foreign oil imports. Those who expected his long silence to be followed by some dramatic gesture were to be disappointed; the content of his speech to the nation was confined to proposals which had received wide currency in recent months — holding oil imports to 1977 levels (themselves the highest ever) and paring down imports by a half over the next decade, developing synthetic fuels, making a more positive start on conservation and so on. Nothing was said about nuclear power. No imaginative political moves were made — but this is not President Carter's style.

At least Carter's aims are relatively modest. At the time of the 1973 energy crisis President Nixon wheeled out a plan, 'Project Independence', of which was intended to make the United States independent of foreign energy suppliers by the year 1980.

Perhaps the most eyecatching proposal is that alternative fuels, notably synthetic fuels, should account for 2.5 million barrels per day by the year 1990. This would be rather more than a tenth of present-day oil consumption. Even this (as David Dickson points out on page 181) is little more than catching on to a recent optimistic public mood that expensive synthetic fuels will eventually be acceptable in the market place. And environmental objections, including those concerning carbon dioxide (see also page 189), will have to take a back seat.

President Carter has chosen to couple his energy message with a deeper warning to the American people that there is a crisis of confidence, moral and spiritual, in the nation. There may be a crisis of confidence in the presidency, and certainly Americans are worried about their future industrial competitiveness, but to bring in moral and spiritual values is surely to confuse the real message: that a whole raft of institutional and social changes are going to be necessary to meet a new era of energy austerity. □

Aldermaston goes a little public

The invitation for a number of members of the press to visit Aldermaston, the centre of Britain's atomic weapons' research, was an unexpected and pleasant surprise. Defence research establishments rarely open their doors, and as far as anyone could remember this was the first time a contingent from the press had been inside the security fence. The purpose of the visit was, from Aldermaston's point of view, to demonstrate their new laser compression facility recently opened by the Queen — a facility which seemed strangely similar to another laser compression facility just 30 kilometres away at the Rutherford Laboratory. Why can't the weapons people and the academics pool their resources (the price tag is, after all, several million pounds) and share a bigger and better facility? The Americans seem to have far less inhibitions about doing defence and academic work in the same building.

But the purpose of the visit, from many of the journalists' point of view, was not so much to look at a laser, nor even at the splendid display of non-weapons-related research gathered in a giant marquee and discretely draped with reminders that a pay dispute was still on. Rather, it was a unique opportunity to fire at the Director of the establishment a whole range of questions about broader issues concerned with nuclear weapons.

The most persistent questioning concerned the return to action of the plutonium facility which had to be closed last August when some workers in it were found to have been exposed to higher than permitted doses of radiation. It seems that as yet a substantial fraction of the facility is still not fully in operation. One of the big problems is manpower — not just skilled craftsmen but also health physicists prescribed by the Pochin report.

Even on this matter the Director and his colleagues were the very soul of discretion. When it came to questions such as 'What is happening under the Polaris improvement programme?' 'What is going to happen to the US/UK agreement on nuclear exchanges, due for renewal this year' and 'How would a comprehensive test ban pose problems for nuclear weapons stockpiles', the discretion was absolute — each was answered with a 'no comment'

It would have been a somewhat disgruntled team of journalists which would have left Aldermston under these circumstances were it not that the message did seem to have registered that the lack of public information on the British nuclear deterrent, particularly at a time at which major decisions are being made, is a matter of some concern. Promises were made that the Ministry of Defence would look into giving the press a fuller briefing in the near future on nuclear policy. The sooner the better. □

Sparks continue to fly in low-level radiation row

David Dickson describes a conflict in paradigms behind differing interpretations of the health hazards of nuclear power

Two and a half months after the National Academy of Sciences submitted to the Environmental Protection Agency the "final draft" of a long-awaited report on the biological effects of ionising radiation, an *ad hoc* committee within the academy is still meeting to re-write the most controversial section of the report, that discussing the appropriate model for interpreting the dose-response relationship for low levels of human exposure.

With public concern at the possible health hazards of nuclear power fuelled by the recent accident at Three Mile Island — and the nuclear industry no less concerned about meeting the costs of a possible tightening of occupational exposure levels — the issue is inevitably a hotly-debated one. Hopes that the temperature might be reduced by referring the issue to the academy, however, have been frustrated by a dispute over the interpretation of scientific evidence as heated as the public controversy outside.

The scientific dispute emerged briefly into public view at a press conference in May, when presentation of the draft conclusions of the academy study was accompanied by a strongly-worded minority statement claiming that the report's conclusions could lead to "detrimental apprehension" over radiation hazards; when additional members of the drafting committee indicated their own reservations, academy president Dr Philip Handler decided that the disputed section should be re-written.

Controversy already surrounds two other academy reports on politically sensitive issues, one on methods of nuclear waste management which was withheld from publication partly at the request of the Department of Energy, the other a massive study on energy policy which is already two years behind schedule. And Dr Handler has now announced that top NAS officials will be taking a close look at procedures for handling such issues over the summer "to see that these type of problems don't happen again."

Concern over the health effects of radiation is as old as knowledge of radiation itself. Until the mid-1960s, the main issue of controversy was whether a threshold exists below which radiation can be assumed to have negligible effect; since then, most scientists have accepted that there is probably no such threshold, and the debate has been over the shape of the dose-response relationship at low levels of exposure.

In a report in 1972, the academy's Committee on the Biological Effects of Radiation (BEIR) suggested that a linear hypothesis, extrapolating backwards from the known relationship at high levels, was the most appropriate to adopt for regulatory purposes — given all the uncertainties involved — and this has been accepted by various standard setting bodies.

However, this hypothesis has been attacked from both sides. Suporters of the nuclear industry claim that it is too restrictive, considerably overstating the risks; on the other hand studies of nuclear workers and others have been reported which, industry critics claim, show even existing exposure levels to be too high.

The BEIR committee, in its new report, sticks to the linear hypothesis as the most "prudent" assumption. Within the committee, however, a fierce battle has raged over whether, and if so to what extent, this assumption overstates the "true" risk. Both sides in the dispute agree that there is insufficient human data to provide statistically valid risk estimates for exposures of less than about 10 rads; where they disagree, with almost religious fervour, is what type of models can be used to fill the gap.

Supporters of the linear hypothesis tend to rely predominantly on epidemiological and statistical arguments. They claim, firstly that there is sufficient evidence from other studies, such as the effects of the medical uses of radiation, to make the linear hypothesis plausible; and secondly that the lack of human data makes it statistically impossible to reach any more precise assessment.

Their opponents, in contrast, tend to rely more heavily on radiobiological data obtained from studies of the effects of radiation on lower organisms. In the minority report attached to the draft of the committee's report, it is stated that "even if the linear model *were* in fact to afford a substantially better fit to epidemiological data, this would be insufficient justification for rejection of models that are consistent with a vast body of radiobiological evidence."

According to the latter arguments, a more appropriate dose-response model (at least for "low energy transfer" radiation, such as gamma rays) would be a quadratic one, possibly with a linear component. The linear hypothesis, they suggest, should only be accepted as an upper limit, with suitable recognition of a low limit of equal validity. "It should then be stated that the true risk is between these limits, and very likely near the lower limit".

Radiobiological data is also given greater prominence in deliberations within the National Council for Radiobiological Protection, a body which, although private, has been attacked by critics for its links to the nuclear establishment. Dr Victor Bond, for example, chairman of an NCRP committee which is soon to produce a report on low level radiation expected to reach different conclusions to the BEIR committee, told a Congressional committee last month that there were "good biological reasons" to support the lower estimates.

Dr Bond referred in particular to studies such as those carried by Dr Harald Rossi, one of the most outspoken critics of the linear hypothesis on the BEIR committee, and colleagues at the Columbia University College of Physicians and Surgeons in New York, on genetic changes in cells of the plant Tradescantia. "Radiobiology in simple systems is important to the establishment of the most-probable dose-effect relationships for the human being" he said, adding that the linear hypothesis for low level radiation was "biologically unsubstantiated".

Nowhere is the difference between the supporters and the critics of the linear hypothesis more marked, however, than in their different interpretations of studies on survivors of the atomic bombs dropped on Hiroshima and Nagasaki.

The critics point for support of their curvilinear hypothesis to studies of the mortality rates from all forms of cancer carried out between 1950 and 1974 on 80,000 survivors in the two cities. Concentrating in particular on the Nagasaki mortality data, this reveals an effect "about ten times lower than that based on proportional projections from persons receiving high X-ray doses" according to Dr Edward Webster of Harvard Medical School, co-author with Dr Rossi of the original minority report.

Supporters of the linear hypothesis, however, look at the Japanese data differently. They criticise the mortality data for its lack of statistical precision (in particular in the light of uncertainties over the relative effects of gamma and neutron components), arguing that "it is difficult to define a functional form in the dose reponse relationship" and that a linear-quadratic curve "is not demonstrably superior to a simple linear fit."

As an alternative, the original draft of the report suggests that it is more useful to look at data on cancer incidence rather than on mortality; and that a registry of solid tumours among Nagasaki survivors — evidence whose validity is questioned by the critics — supports their general hypothesis.

A further dimension to the dispute — and, one that some argue, is largely fuelling it — has been a sharp difference in attitude towards the nuclear power industry. Dr Edward Radford of Pittsburgh University, chairman of the BEIR committee, has made little secret of his personal views that current permitted exposure levels for nuclear workers are unnecessarily and perhaps dangerously high, suggesting that exposure levels be

0028-0836/79/290180-02$01.00

Macmillan Journals Ltd 1979

reduced by a factor of up to ten.

"The purpose of requiring more restrictive occupational exposure limits is to provide clear design criteria to allow engineers to design facilities to meet these kinds of standards, rather than rely on the somewhat nebulous and legally dangerous to the industry 'as low as reasonably achievable' concept," he says.

The dissenting group on the BEIR committee has made it equally clear that it feels too restrictive exposure levels could place an unnecessarily heavy burden on the nuclear industry. The original minority report warns that overestimates of radiation hazard could result in "serious detriment" to national energy policy. "If the guide line levels were reduced in the way [Radford] wants them, there would not be any nuclear industry at all" one committee member has been quoted as saying.

The BEIR committee dispute has been characterised as a conventional scientific disagreement. "Such controversies have existed within the scientific community since time immemorial. We will truly be in trouble when scientists passively accept each other's work without challenge," says Dr Sidney Marks of the Battelle Memorial Institute's Pacific North-West Laboratory.

In this case, however, the incentive has been primarily provided not by a desire for knowledge, but by a specific regulatory need; and the resulting impasse therefore carries both scientific and political dimensions. Initially the academy had hoped that this could be accommodated in the minority report; however when it emerged that over half of the BEIR committee's somatic effects subcommittee shared the reservations about the degree of support given to the linear hypothesis, it was decided that a redrafting of the whole section to produce "a more balanced expression of differing interpretations" would be more appropriate.

The new version will, it is hoped, be ready for re-submission to the full committee within a few weeks. The academy still says that "dissenting views will be published in the final report"; so whatever is agreed is unlikely to be taken as the last word. □

US scientists warn of environmental dangers from synthetic fuels

As President Carter was preparing the details of a major national programme to stimulate the production of synthetic fuels, announced in his energy speech last Sunday, the Council of Environmental Quality released a report warning that a rapid increase in the use of synthetic fuels could have serious environmental consequences through speeding up the accumulation of CO_2 in the atmosphere (see also page 189).

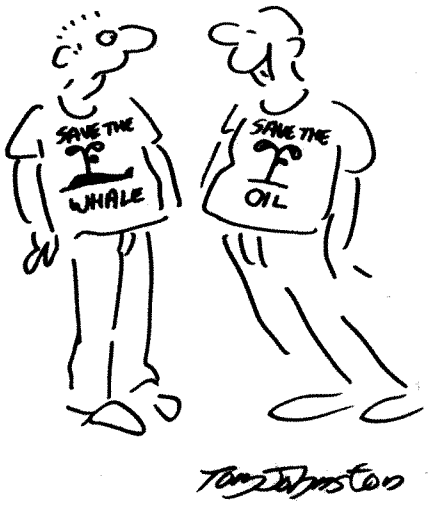
Synthetic fuels, previously a relatively unfashionable area of research, have suddenly been receiving the enthusiastic attention both of the President and of the US Congress.

Despite wide uncertainties over both economic and technical viability, the House of Representatives has already passed a bill authorising a crash development programme aimed at a target of producing 2 million barrels of synthetic fuel a day by the year 1990. And in his energy speech, delivered after almost two weeks of closeted discussion with his top advisers, President Carter proposed a programme that would develop America's alternative fuel sources from coal, oil-shale, plant products and the Sun to replace 2.5 million barrels a day of imported oil by 1990.

However both environmentalists and scientists have expressed concern at the environmental implications of such programmes, urging the President to concentrate on means for achieving energy conservation rather than the search for substitute fuels.

In a report to the CEQ, the four scientists say that the production of CO_2 resulting from the use of synthetic fuels (such as gas or oil) made from coal is almost 50% higher than the CO_2 emissions resulting from the production of energy directly from coal, and twice as high as the result of obtaining an equivalent amount of energy from natural gas.

"It is our conviction that an appropriate reaction to the mounting worldwide squeeze on supplies of energy requires consideration of the CO_2 problem as an intrinsic part of any proposed policy on energy," the four scientists say.



Environmental groups have warned the President about other potentially damaging aspects of a massive synthetics fuels programmes, ranging from the disruption caused by the construction of large production plants to the creation of large quantities of carcinogenic substances.

In a letter sent to the President last week, five such groups urged that he not allow himself to be caught up in what they described as a "synfuel panic", and consider lower-cost conservation programmes as an alternative to a massive commitment to synthetic fuels.

Many of the environmental risks associated with such a commitment were "unacceptable", the groups said in their letter; emphasis should rather be placed on more solar development programmes, less costly programmes for synfuel development, and more oil and gas exploration.

Support for such a policy also came from a different direction, namely a study prepared by the Harvard Business School, soon to be published by Random House under the title "Energy Future". According to this study, the need to constrain oil imports is much greater than most economists and energy analysts have realised, since the political and other costs of dependence on a few producing countries has to be included on top of the market price for oil.

The Harvard study suggests a diverse national energy policy encouraging modest growth in the use of coal, some reliance on nuclear power, and continued efforts to develop synthetic fuels; however it argues that in the current political climate, a stepped-up programme to accelerate conservation and solar energy would prove far more rewarding than any other energy path.

Tom Johnston

The environmental hazards associated with a major synthetic fuels programme were also covered by a report published last week by the Department of Energy's Office of Technology Impacts. Although the report says that it should be possible to find acceptable sites for large synthetic fuels production plants, it warns that successful commercialisation does have environmental risks, and that stringent environmental controls, management practices and "permitting conditions" should be maintained.

The Department report says that deployment of synthetic liquid facilities on an accelerated schedule to 1990 appears feasible in terms of current environmental constraints, although a target of 2 million barrels a day, rather than 500,000, would bring "rapid siting difficulties".

In reaching its conclusion, the report says there is some risk that environmental research and development programmes cannot fully satisfy all existing and expected regulatory demands, but that these risks should be known by 1985, and it is expected that appropriate control adjustments can be made.

"Reduction of these uncertainties requires refocusing of environmental research and assessment programmes to aggressively address these areas", the report says. **David Dickson**

Congress slows growth of biomedical research

Appropriations committees in both the US House of Representatives and the Senate have recommended increases in the amount of money requested by President Carter for biomedical research in his budget proposals for the fiscal year 1980, submitted to Congress at the beginning of the year. However the increases, which average about 6% over the amount spent by the US on such research in the current financial year, is less than the expected rate of inflation — and considerably lower than the 24% increase over the President's proposal voted by Congress last year.

In his budget message, the President proposed that the research budget for the National Institutes of Health should remain virtually static, at about $3.2 billion, between 1979 and 1980. Of particular concern to many research workers had been the proposal to reduce from 5,673 to 3,062 the number of new grants and competing renewals for investigator-initiated research (implying a drop from 42 to 20% of those approved for funding actually receiving support).

On the advice of its appropriations committee, the House has recommended that the NIH budget be increased next year by $202 million — or 6.4% over the current year; the major proportion of this increase will go to support investigator-initiated research in the various institutes, with the aim of increasing the number of new grants to 5,000.

"Thus the bill continues the real growth in federal support for basic biomedical research which has prevailed in recent years", the committee says in its report, adding that its primary objective "is to allocate funds to the most promising research endeavours as determined by the peer review system".

The committee also says that the present balance between non-competing continuations, competing renewals, and new grants "warrants a careful review to determine whether current procedures and mechanisms leave enough room for the support of unconventional ideas and new investigators without proven 'track-records' ". It has requested the director of NIH, Dr Donald Fredrickson, to undertake such as review and to make a report before 1 October.

It also suggests that the NIH should explore the possibility of starting a programme to awarding stipends to medical or dental students to spend brief periods engaged in health research projects, with the hope of attracting them to research careers and thus increase the number of MDs and DMDs going into basic and clinical research.

The Senate is yet to vote on appropriations for biomedical research. However the Senate's appropriations committee last week accepted the proposal of its subcommittee that would cut $13 million of the increase proposed by the House, still leaving intact an increase of 6% over the current year's funding. A single figure has to be agreed by both the House and the Senate before the appropriation can become law. □

Germany's research minister calls for 'critical science'

WEST GERMANY wants its scientists to be more critical in their research and to give due consideration to the disadvantages of technological advances as well as the advantages. There should be more discussion with pressure groups and the public before fundamental decisions on, say, nuclear energy are made.

This change of emphasis in Bonn's research and technology policy was outlined by Research Minister Volker Hauff when he released a major directory of research in West Germany recently. The 650-page report — *Bundesbericht Forschung VI* — is the Bonn government's sixth assessment of research policy, institutions and financing.

Hauff said the risks of research and technical progress should enter into decisions more than before. The government wanted to be more critical, to analyse and take account of the advantages and the disadvantages of new developments and to hold a dialogue with trade unions, individual population groups and pressure groups *before* taking decisions, not afterwards.

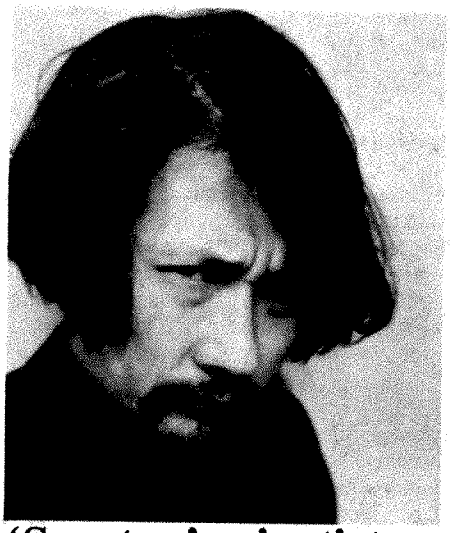
There is now a growing protest against almost every new large-scale technical construction in West Germany, even down to pressure groups against new roads and railway lines. Among the fields whose disadvantages need more critical examination, Hauff mentioned genetic engineering, the investigation of new sources of energy, and the widespread introduction of microelectronics. On the other hand, the research report, despite all the criticisms and objections surrounding Gorleben, still stands by the government's controversial "integrated disposal" policy for getting rid of the waste from nuclear power stations.

The report records a total expenditure of DM30,000 million for research and development last year, of which half came from the state and half came from industry. It amounted to a 2.3% share of the gross national product. The main focus of R&D expenditure by the federal government (totalling DM8,500 million) was on the Federal Ministry of Research and Technology's promotion programmes (DM4,700 million) and on the Defence Ministry's research expenditure (DM1,700 million). The Länder on the other hand finance research mainly in the universities and other colleges.

The growth rate of the total R&D expenditure in the Federal Republic has declined from 20% per year in 1969 to 8% in 1978.

Within the R&D expenditure, the proportion for defence research and other government departmental research is declining, while that of the Ministry of Research and Technology's promotion programmes is rising slightly. The proportion of basic research fell from 19.5% in 1975 to 16.5% in 1979, but should rise again slightly to 17.1% by 1981.

The report also explicity catalogues the aims of research and technology policy. In addition to the earlier three aims — expansion of scientific knowledge, increase in economic efficiency and improvement in citizens' living and working conditions — there are now a further two: the conservation of resources, and the "improvement of knowledge about technological risk", to provide a better basis for decision making. As far as possible, all five aims are to be pursued with equal vigour. The inference is that the previously dominating emphasis on economic interests is to yield gradually in favour of a broader outlook. To what extent the non-economic aims stand a chance of realisation is, however, questionable.



This is evident in the Federal government's stress on how little latitude there is for 'going it alone' in the face of international competition, and in the increasing recognition that national decision-making mechanisms set narrow limits on its research and technology policy. While Research Report V was still saying briskly in 1975: "Research policy must investigate needs, evaluate various possible solutions . . . and set priorities"; this time the language is more reserved: "In an organisation of research which has, for good reasons, been designed pluralistically, government research promotion can and may lay emphasis on matters of content within a limited compass only."

Klaus Höpfner

●According to their annual report for 1978, just published, the Deutsche Forschungsgemeinschaft (which funds much of Germany's research in universities) spent over 700 million DM last year for more than 10,000 projects in all branches of science and research. The biosciences shared the largest fraction of the money, although their share sank from 37.1% (1977) to 36.2% (1978). The other natural sciences augmented their share slightly to 24.7%, while engineering sciences fall 0.5% to 20.9%. The most rapid increase came in the social sciences, which grew 17% from 1977 to 1978. □

'Spartan' scientist must go, says UK

Dr Tetz Yoshimura (above), the Japanese mathematical physicist, who seeks to stay in Britain and pursue his research undisturbed by the 'rat race' of modern Japanese life, is to be deported from Britain. His appeal against deportation was rejected last week by the Home Office on the grounds that his position "presents insufficient unusual features to justify giving him favourable treatment".

This represents a shift in standpoint from previous Home Office notifications, which rejected his application to stay on the grounds that his income from freelance coaching and translation work was insufficient to maintain him. Although Dr Yoshimura's spartan life-style allows him to maintain himself on £12 per week (half his average income), further guarantees were required. When the author Russell Hoban came forward as financial guarantor, the Home Office dropped the financial aspect, and turned to the fact that Dr Yoshimura's various academic committments had terminated — not surprisingly, since coaching and the marking of examination papers is not normally required during the long vacation.

It seems strange that the Home Office claims the case exhibits no unusual features. Dr Yoshimura is an example of a now almost extinct race of scientists who hope to work without the support of major public funding bodies. When he came to Britain in 1971, he hoped to find a haven of academic detachment. Even the bulky file of correspondence on his case contains the occasional off-print or letter from an academic publisher about the proper placing of a bracket, that have somehow crept into the official hassling.

Faced with the final deportation order, Lord Avebury, chairman of the inter-party parliamentary Human Rights Group told *Nature* that he hoped that Dr Yoshimura's scientific colleagues would bring all possible pressure on the Home Secretary to reverse his decision.

Controls urged on mineral fibre

A unique government-industry-trade union working party organised by the UK Health and Safety Executive has proposed controls on mineral insulation wools used as substitutes for asbestos, and called for a programme of research to define further the hazards of fibres.

The report estimates that 15,000 workers are involved in the production and steady use of man-made mineral fibres (MMMFs) with up to 250,000 workers coming into "occasional" contact with MMMFs. In addition, the Chairman of the Party, D J Evans estimates that perhaps 20 times this number handle the materials privately.

The fibres are produced from glass, rock, slag and metallic oxides and include fibreglass and rock and slag wools which are widely used for home insulation as a substitute for asbestos. The proposed limits are a fibre limit of five fibres/ml and a mass limit of 5 mg/m^3. (The present limits for asbestos exposure are 2 fibres/ml which is expected to be lowered to 1 fibre/ml shortly. The National Institute for Occupational Safety and Health in the US has proposed a new limit of 0.1 fibre/ml.) The time for introduction of the MMMF standard is "not to exceed three years".

In separate appendices, the trade union and industry representatives express the fundamental conflict in hazards legislation over who is to pay — industry in the form of safer equipment, or the work force in terms of poor health and possibly early death. Industry contends that no hazard has been shown to exist and as such controls must be based strictly on cost. "In the absence of a scientific basis upon which any changes in the (general dust standard) can be made, any change must be based upon what is considered to be the best practicable engineering controls."

Industry is willing however to support the introduction of a standard. "While emphasising the absence of a scientific basis for the figure we accept the proposed standard of 5 fibres/ml." This standard is not expected to affect industry operations significantly.

In their statement the TUC states that it would prefer a standard of 1 fibre/ml and feels it could live with a standard of 3 fibres/ml as "an acceptable and attainable standard under present engineering control knowledge." The TUC disagrees with the 5 fibre/ml standard and it also disagrees with the three year lead-in period, calling instead for adoption of the standards within 12 months.

In the middle of the political fight between those who assign the limits, and those who bear the risks, stand the scientific specialists. In the UK, research into the hazards of fibreglass is being conducted at three places. In Southampton, Professor Donald Acheson will conduct human epidemiological studies. In Edinburgh, the Institute of Occupational Medicine is working on standardisation techniques, and at Penarth a Medical Research Council unit will conduct animal studies as well as designing measurement devices. Additional research is being conducted by the industry funded. International Agency for Research into Cancer with support of the World Health Organisation.

Experienced health and safety observers, however, point out that the situation bears an uncomfortable resemblance to the history of asbestos. In the UK, the first cases of asbestosis were reported by lay people in 1898, and the government noted cases of death in 1900. But the first legislation was not introduced until 1931, and widespread public awareness of the extent of the hazard did not occur until the 1970s. Fibreglass and its cousins are relatively recent materials and the historical data may not even exist.

Dr Morris Greenberg, medical adviser to the Health and Safety Executive thinks that the situation is difficult. "We think that MMMFs are not in the same league as asbestos but we don't know how far down the leage table they are." **Joe Schwartz**

Man-made Mineral Fibres. Report of a Working Party to the Advisory Committee on Toxic Substances. HMSO. 50p.

Asbestos, not glass fibre, killed woman

Scientists at the US National Institutes of Health announced last week that a case of pneumoconiosis reported by Japanese research workers last autumn as possibly being related to exposure to glass fibre had turned out to be the result of previous exposure to asbestos. The link between glass fibre and pneumoconiosis had been suggested by a Japanese research worker at a meeting last year held under the auspices of the National Cancer Institute, following his discovery of physiological damage in the lungs of a woman who had worked with glass wool similar to the damage caused by asbestos fibres.

The report received considerable publicity, and generated wide concern in the glass fibre industry. However the NIH reported last week that microscopical analysis of biopsy material carried out by Dr I J Sellikoff of the Mount Sinai School of Medicine showed the presence in the lung of asbestos fibres, but not glass fibres.

The NIH report says that during discussion of the original report, it was understood that six other cases of pulmonary disease had been found. "The existence of these cases cannot be confirmed and is attributed to a linguistic error", the NIH says.

news in brief

IWC offers some hope for sperm whales: Conservationists won a half-victory at last week's International Whaling Commission meeting after years of unsuccessful campaigning. There will now be an indefinite ban on factory-ship whaling for sperm whales, and a whale sanctuary will be set up in the Indian Ocean for ten years. About 7,000 sperm whales will be saved by the factory-ship whaling ban, which will probably put an end to the Russian whaling fleet. The small minke whale, however, has not received the same protection. Commercial minke whaling has been excluded from the IWC moratorium, and the Antarctic end of the Indian Ocean where the minke is found in great numbers will not form part of the sanctuary.

The IWC also set a new quota of 16,000, some 4,000 less than last season's kill. Recommendations were made by IWC's technical committee on humane methods for slaughtering whales but no nation offered to allow independent observers on to their ships, so research on death times and killing methods will be difficult. The IWC also agreed that scientific permits and quotas on the number of whales needed for research would now have to be approved by a science committee. Previously each nation set their own quotas.

Conservationists were disappointed that a proposal to ban all sperm whaling was rejected by the IWC and that shore-based sperm whaling will continue. The commission also rejected a proposal to prohibit trade between IWC and non-IWC nations, and a proposal to add the narwhal and white whales to the IWC's list of protected species. The commission also failed to come to a decision on pirate whaling.

Malformations at birth increased in Séveso last year: Figures issued by the special regional commissioner for Séveso, Mr Antonio Spallino, suggest that there has been an increase in the past year in the number of local children born malformed. According to Spallino, of 2,777 births recorded in the Séveso region in 1978, 90 infants were born malformed and 24 were classed as 'doubtful cases'. The comparable figures for 1977 were 2,756 births, 41 malformations and 25 doubtful cases. In July 1976, a trichlorophenol reactor belonging to the Givaudan company at Séveso, overheated, discharging its contents — including a teratogen 2,3,7,8 — tetrachloro-dibenzo-p-dioxin (dioxin) — over a populated area near Séveso in Italy. Concern was expressed at the time that the presence of dioxin, a well-known teratogen, could lead to an increase in birth malformations. The current figures do suggest such an increase, although the rate of malformations reported for 1978 is still comparable with the norm for Western Europe and bears little relation to the concentration of dioxin.

MRC staff committee criticises MRC management for budget cut inaction: Officers of the National Staff Side of the UK Medical Research Council have mounted a campaign to oppose cuts in the medical research budget, that includes strong criticism of MRC officials. The committee cites the closure of two MRC units and the future loss of 380 jobs or 10% of the workforce as evidence of the damage being done to the nation's research effort. "We do not agree that the Council should implement or even accept the imposed cuts. The MRC seem to have done nothing to offer resistance on their own account and have refused to be associated with our protests." Officials in the MRC claim that further assessment is needed and that management has its own separate channels of communication with government. "No figures yet exist for losses due to budget cuts and the two unit closures were for scientific not economic reasons" an MRC official told *Nature*. "The official side has made its views known to the government through the Advisory Board for the Research Councils." The Council's views have not been disclosed pending a Council meeting called for 19 July.

Aldermaston unions to file contamination lawsuits: Four trade unions at Aldermaston, the UK's nuclear weapon laboratory, are considering more than 70 claims for damages against the Ministry of Defence for plutonium contamination. The action follows the unions' refusal last February to work in contaminated areas identified by the Pochin report. The report was produced by Sir Edward Pochin, a radiologist, after plutonium had been found in the lungs of three workers in the laboratory's laundry room. Nine workers in the industry-chemistry section were also contaminated.

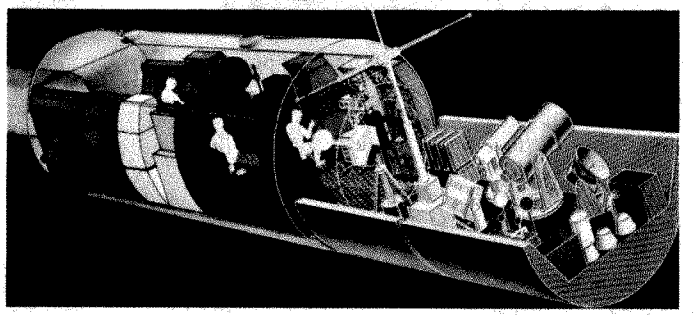
Sussex students now expelled: Sussex University students Richard Flint and Shaun Fensom have been expelled from the university for their part in preliminary science examination disruptions. The expulsion was the result of a second disciplinary committee action announced on 6 July. A faculty committee consisting of pro-vice Chancellor Professor T Nuttal as chairman and four faculty members, M Hawkins, W Lamont, L Cook, and J Maynard-Smith, appointed by the university Senate had reinstated the students on 25 June — provided they were "not found guilty of a further breach of discipline as defined by the disciplinary code after this judgement". One week later the committee reconvened to consider the student disruptions of the week of 18 June as a separate series of events from the first disruptions in May. The June demonstrations saw the breaking down of doors and the first arrests and injuries, when faculty members confronted a picket line of 150 students in front of the Building of Engineering and Applied Science. A faculty petition signed by over one hundred faculty members — few of them from the science faculty — called for the reinstatement of the two students (as well as a withdrawal of threatening letters to university student rent strikers (21 June)) to no avail.

In addition criminal charges of malicious intent to cause damage have been filed against five students and the university has taken out a £20,000 order of compensation against five students and a £10,000 order of compensation against the student union.

UK government scientists win claim; strike goes on. Scientists of the striking Institution of Professional Civil Servants have won their pay claim for this year. The Civil Service Department has granted pay rises in five scientific grades ranging down from 34.1% for the top grade of Principal Scientific Officer to 22% for Assistant Scientific Officer. The rises are linked to those for administrative grades — a hotly contested point. In what has become an increasingly bitter series of negotiations the IPCS has also won its demand that next year's salaries are to be negotiable. The CSD had demanded the union accept without negotiation the results of a pay research exercise to determine their pay.

In the meantime the IPCS in still on strike in support of claims for the governments 40,000 technologists — an action which is supported strongly by the scientists. Government scientists at Royal Ordnance factories at Glascoed, South Wales and Bradeway Green and Chorley both near Manchester have brought shell manufacture to a halt. In addition scientists at the government's Forensic Laboratory withdrew their labour in a two week strike but, because of the Official Secrets Act, could not disclose the effect of their action even to the union leadership. The IPCS has called for arbitration and is continuing its tactics of selective strikes, half day strike-demonstrations and withdrawal of good will.

NASA orders a Spacelab from ESA: On 5 July, NASA signed a contract with the European Space Agency for the supply of components for a second Spacelab flight unit identical to those of the first Spacelab unit which ESA is currently building. The cost to NASA of the second Spacelab will be announced by ERNO, the



0028-0836/79/290184-02$01.00

© Macmillan Journals Ltd 1979

German head of the consortium which will be building it, at the end of this month. NASA hopes however, that it will not exceed 110 million accounting units (1 a.u. is $1.25).

A memorandum of understanding that NASA should buy a second Spacelab from ESA was signed when the two agencies first embarked on the Spacelab programme. During much of last year, ESA and NASA spent time trying to think of ways in which NASA could procure the second Spacelab without any exchange of funds. A system of bartering, however, was unattractive to ESA which was reluctant to provide a Spacelab in exchange for free shuttle flights for some of the first Spacelab's demonstrations missions. Difficulty in filling some of the demonstration missions with sufficient experiments, mainly because of costs, meant that ESA could not guarantee in advance that it would use the shuttle flights it had bartered for. The two agencies therefore finally agreed to revert to the normal way of selling and buying by exchange of funds.

Funding of the first Spacelab is currently undergoing some difficulties, however. Present estimates of the total cost are now 680 million accounting units, about 140% of the original estimated cost. Under the Spacelab agreement, any participating state is entitled to leave the programme when costs rise to 120% of the original estimate. In principle, however all states want to continue despite the 40% overrun — but some, notably Italy, are finding difficulty in raising the funds.

Another factor which could add further to costs is a possible further delay to the Spacelab launch caused by difficulties with the space shuttle. Despite the recent statement by Dr Robert Frosch, NASA's administrator, that the space shuttle's first operational flight will now be delayed until September 1981, however, ESA has received no formal notification of any further delay to the first Spacelab launch most recently scheduled for August 1981.

Religious leaders criticise links between knowledge and power: Scientists and technologists have weakened their claims to intellectual freedom by showing bias on the side of those who wield economic power, according to Dr Philip Potter, general secretary of the World Council of Churches. Addressing the opening session of a two-week conference on science and religion in Boston last Thursday, Dr Potter said that there was little sign that scientists were on the side of the oppressed, the deprived and the "marginalised".

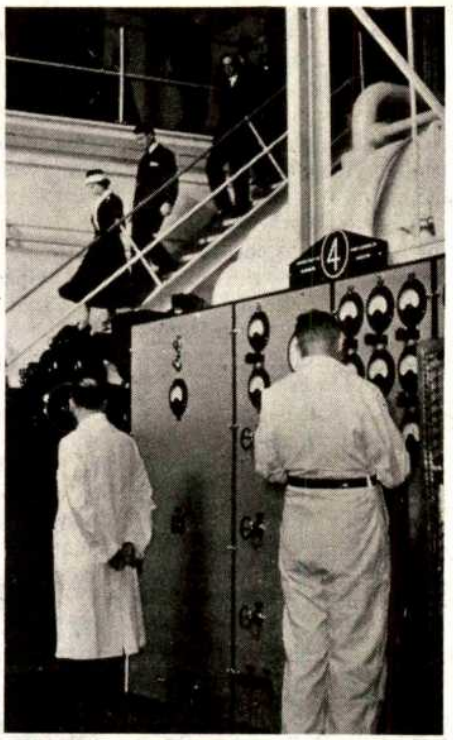
"Science and technology might claim to be objective and universal, but this claim is not born out in reality," said Dr Potter, who is a methodist minister in Jamaica. "Science and technology are not neutral or value-free but are instruments of power, and that means political power"; a leading issue of the conference was therefore how ways could be found of allowing the public a greater share of decisions on how science should be employed.

In contrast to Dr Potter's comments, Dr Robert H Brown, an astronomer from the University of Sydney, Australia, defended science against claims that it had been corrupted through colluding with the powerful against the interests of the poor. "Some tell us that the ideals of science have been so eroded by its alliance with power that it has little to offer us," he said. "I suggest that it is no more a valid reason for turning away from the values of science than it was for scientists to turn away from the Christian faith."

Laetrile claimed to increase size of tumours: Doses of the controversial drug Laetrile, which some claim to have anti-cancer properties, has been shown to increase the size of tumours in rats, and eventually lead to cyanide poisoning, according to the report of two US medical research workers in the *Journal of the American Medical Association*. The researchers, from the Northwestern University medical school, say that doses described as "realistic in terms of human ingestion" led to a progressive increase in the size of tumours when administered to rats, and as the dosage was increased, so to did the incidence of death from cyanide poisoning. "The findings seriously question the use of amygdalin [Laetrile] in clinical medicine under any circumstances" said Dr Janardan D Khandekar, one of the scientists involved.

Meanwhile the Food and Drug Administration has rejected the charge from one of its staff scientists that it is unethical for the agency to study the effects of Laetrile, as has been requested by the National Cancer Institute, even though there is no scientific evidence of its efficacy.

In reply to a citizen's petition filed by Dr Robert Young, the agency has said that it does not consider such studies to be unethical since the tests might provide some useful information. "The ethical aspects of failing to discover a useful cancer drug are complex and not well explored, but the prospect of such an outcome occurring because of intellectual rigidity or over adherence to an ethical dogma is unsettling," replied Dr Richard Crout, director of the Bureau of Drugs, although admitting to "a great deal of ambivalence" on the matter.



Germany's science council recommends sites for new polar research institute: The federal government of West Germany, which aims to join the consultative round of the Antarctic Agreement, wants to strengthen polar research activities in the FRG and therefore decided some time ago to establish a central polar research institute "as soon as possible". Last month, the Science Council (Wissenschaftsrat), which was asked to advise, welcomed the initiative and made some detailed suggestions for the new 30-scientist establishment.

The Science Council recommends that the institute should set up as a foundation under public law and financed equally by the federal government (the *Bund*) and the *Land* where it is situated. It should be responsible for the planning, construction and operation of the German research station in the Antarctic and direct the operation of the ice-breaking research and supply ship in the polar regions. Moreoever, it should have an important function in co-ordinating national and international polar research activities, thereby co-operating with other institutions acting in this field and building on a long-standing tradition of German polar research. Concerning its location, the Science Council recommends that it should be established in the neighbourhood of a large university with internationally proven research in the relevant fields. The Science Council therefore put Kiel at the top of the list, Hamburg next, and Bremen (including Bremerhafen) third. Among the three towns, Hamburg has rejected the institute, as it is fully occupied with establishing a new technical university. Kiel, on the other hand, is showing a strong interest, but faces strong political objections in Bonn.

India to launch oceanographic research vessel: An oceanographic research vessel will be commissioned by 1981 for research and development of marine resources in India. The Indian government's decision to acquire the vessel is in line with the government's recognition of the importance of ocean waters and the sea bed as store of living and nonliving resources. Earlier, the Government of India had enacted the Maritime Zone 1976 which reserved the right of survey and exploration of the marine resources of a 320 km 'Exclusive Economic Zone' and the continental shelf exclusively for the Indian people. To ensure optimum utilisation of research facilities and proper co-ordination the Ocean Science and Technology Agency (OSTA) was set up in 1978. The research vessel is to be manufactured in the Federal Republic of Germany.

UKAEA: boom or bust?

Two years after the establishment of the United Kingdom Atomic Energy Authority 25 years ago, the Queen was opening the world's first full-scale nuclear power station at Calder Hall (see right). But these early boom years of British nuclear power are over. Energy forecasts are drastically lower, and uncertainty about the future of the industry has led to the loss of key staff. The fast breeder design team, for example, has been virtually disbanded. So even if the new government wished to re-invest in the nuclear industry — as the Prime Minister indicated at the recent summit meeting in Japan — it would first have to re-establish confidence in the industry itself. So while Britain's new energy ministers, headed by Secretary of State David Howell, consider the formation of a new energy policy for Britain, we asked **John Surrey** of the Science Policy Research Unit at the University of Sussex to give us his view of the future of nuclear power in this country. On a following page, **Paul McDonald** considers the difficulties facing another major energy option — conservation.

How the UKAEA might survive

LONG-term forecasts given at the UK National Energy Conference in June 1976 pointed to a future 'energy gap', due to rapid growth in demand and rapid depletion of British North Sea oil and gas reserves. They indicated that without major investment in coal and especially nuclear power, the UK would have to rely on increasingly large and expensive oil imports after about 1990. Only the gas industry challenged the forecasts, arguing that North Sea supplies would last until at least 2000. For the other fuel industries, high demand forecasts promised security and expansion.

Coal's target capacity for 2000 was set at 170 million tonnes — the maximum attainable given the need to replace a large proportion of current capacity and the long lead times for major projects such as the development of the newly discovered coal-fields at Selby and Belvoir. The same climate encouraged the UKAEA (Atomic Energy Authority) to present a 'reference' programme which envisaged 104,000 MW of nuclear power in operation by 2000, including 33,000 MW of fast reactors. These were to be preceded by a 1,300 MW demonstration plant, originally code-named CFR-1 and later CDFR. The 'reference' programme would require about 6,000 MW of nuclear plant to be built *each year* — somewhat more than the total nuclear generating capacity in service today.

A recent consultative document, the 1978 Green Paper on energy policy, contained much lower demand estimates for 2000 — 450-560 mtce (million tonnes of coal equivalent). For comparison, the mid-point of the 1976 forecasts was 558 mtce and the top of the range was 760 mtce. The 1978 official forecasts were very close in several respects to those published by Chesshire and me shortly before the Green Paper appeared. The two sets of estimates were very close for final energy consumption and, in the 'high' case, for primary energy. But in the 'low' case the Green Paper estimate of primary energy demand was 115 mtce higher than ours (see Table 1). Given the other similarities, this big difference can only stem from an assumption behind the official forecasts that electricity consumption, and therefore conversion losses, will be much greater than we estimated under the 'low' case. The discrepancy simply illustrates that the prospects for electricity are one of the biggest uncertainties in energy planning — which is of key importance for coal and nuclear power, given their dependence upon electricity generation.

Until nuclear power stations can work satisfactorily and economically under highly variable load conditions, the scope for nuclear power will be limited to base load generation. In the UK, it is further restricted by a large plant surplus, including a large amount of plant still under construction. Furthermore, electricity is expensive relative to other fuels: in the industrial market the price ratio of electricity is 5.4 relative to gas, 6.1 relative to coal and 3.8 relative to oil.

As long as the relative price is so high, electricity will not substitute for oil and coal in competitive crude heat uses, or for gas in many premium uses. Even assuming that nuclear-generated electricity will henceforth be cheap relative to oil and coal, the fact that nuclear power currently

Table 1 1978 Forecasts of UK Energy Consumption in 2000

	1977 Actual	Forecasts for 2000 SPRU[1]	Green Paper[2]
		billion therms	
Domestic	15.0	14.2—16.2	(13.6)—15.8
Transport	13.1	17.2—19.9	(15.8)—17.0
Other final consumers	7.6	6.0— 8.7	(7.0)— 9.0
Iron and steel	4.9	3.7— 8.4	(7.0)— 9.9
Manufacturing industry	17.9	19.6—28.2	(20.0)—25.4
FINAL ENERGY	58.5	60.8—81.4	(63.4)—76.8
		million tonnes of coal equivalent	
Coal	122.7	83—162	170[3]
Oil	136.6	124—224	150
Natural gas	62.8	88	50—90
Nuclear and hydro	14.3	40—102	95
PRIMARY ENERGY	338.4	335—577	(450)—560

accounts for only 13% of electricity supplied to the British grid means that the price of electricity will not fall appreciably relative to the price of oil and coal until base load is supplied predominantly by nuclear power stations. That, of course, would involve a large nuclear programme to replace the fossil fuel power stations built in the 1950s and 1960s and — since two-thirds of British coal output goes to power stations — a big fall in coal demand.

One is inescapably drawn to the conclusion that electricity demand growth over the next two decades will continue to be low, especially if the supply of North Sea gas reaches 6,000 million cubic feet a day in the early 1980s and remains at that level until 2000. In these circumstances, electricity demand growth will be chiefly in certain premium uses where electricity offers advantages which outweigh its high price. Information available on domestic appliance ownership levels and industrial process applications indicates that the growth potential from these electricity-specific uses is quite small.

Compared with the earlier 104,000 MW 'reference' programme the 1978 Green Paper sees a nuclear component of 25-40,000 MW in 2000, implying the construction of only 1-2,000 MW annually from 1985. The central question now facing the nuclear industry is no longer whether it can muster the skills and resources to build a large programme, but whether it can survive a long period of low home ordering and continued difficulty in exporting.

Following Ince B, Drax B and two new advanced gas cooled reactor orders, further advance orders for power stations should be out of the question on cost grounds. It is therefore urgent to identify the resources and skills that are specific to nuclear design and engineering and to examine how they can best be organised and retained against the time that series ordering can take place. This problem must have precedence over the fast reactor question, for it would be sheer folly to develop fast reactor technology without ensuring that the design and manufacturing base is there so that nuclear power stations can be built efficiently when they are needed. If there is a solution, it is likely to require the rationalisation of the whole power plant manufacturing industry, including nuclear design and construction and large steam turbine generators.

The recognition that long lead times make it impossible to install a significant fast reactor programme by 2000 now seems to have brought a corresponding change in the reason adduced for proceeding with the demonstration plant. When CFR-1 was regarded as the first of a large fast reactor programme, it could be held that costs of the demonstration plant over and above the costs of the cheapest alternative power source (a light water reactor, for example) would be recouped from the benefits accruing from the commercial fast reactors that were soon to follow.

Since the justification was primarily economic, it was possible to argue that CFR-1 would carry no opportunity cost in terms of other R&D projects. Questions about resource allocation were answered by the claim that the programme as a whole would show a large and positive net present value after applying the test rate of discount that is applied to public sector investments. As long as it appeared tenable to argue that the cost of CFR-1 would be recouped from the subsequent commercial programme, the relevant economic questions concerned the estimated capital and operating costs of fast reactors compared with thermal reactors and the estimated long-run supply and price of uranium. Both questions involve major uncertainties and evoke widely differing views.

If, however, approval for CDFR is seen as carrying no commitment to build a programme of fast reactors before the turn of the century, the choice must be seen primarily in the context of R&D strategy. If the commitment which is sought is for CDFR alone, not for a subsequent programme, the question of R&D opportunity costs looms large — the resources must come from somewhere and something will have to be foregone. Unless it is reasonably certain that a highly economic programme will follow in the not-too-distant future, the question of economic risk becomes very important with an R&D project costing £1,500 million or more. Such a commitment to any single R&D project can scarcely fail to affect the climate of opinion and the funds available for alternative R&D options. We therefore need to be quite sure that an equivalent funding of alternative technologies (not only in the energy field, of course) will be less rewarding than building CDFR.

The argument that Britain should acquire the capability to build commercial fast reactors as an insurance against long-term uranium scarcity involves a political judgement. It requires a decision on the acceptability of the whole range of risks and the appropriate rate of social time preference, how much the present generation is prepared to forego for the well-being of future generations.

Another argument in favour of CDFR, the 'export' justification, is wholly spurious for no one can say whether there will be opportunities 20 years hence to export 1,300 MW fast reactors. So far, domestic markets in the USA, Japan and most of Western Europe have been closed to imports of nuclear reactors. Whether the developing countries can accommodate 1,300 MW generating units on their power systems is a moot point. And on foreign policy grounds it is surely unwise for the UK to appear willing to promote exports of fast reactors (and the plutonium to fuel them) before rigorous international safeguards for reprocessing and the commercial use of plutonium are agreed and implemented.

If the political judgement is that Britain should acquire the capability to build fast reactors in the future, the relevant question then is how to proceed. Several further questions must then be answered, because building CDFR is only one of the options for acquiring this capability.

Firstly, why is it necessary to scale up to 1,300 MW? Doesn't the ability to replicate and perhaps stretch the 250 MW Dounreay prototype fast reactor give sufficient insurance against the risk of long-term

uranium scarcity? If there are compelling technical reasons for scaling up, why not concentrate R&D effort upon the specific, critical metallurgical and engineering problems, as opposed to building a 1,300 MW power station costing at least £1,500 million? In any case, the performance of very large conventional and nuclear generating units hardly inspires confidence that the proposed scaling-up is economically justified.

Second, since France and Germany are intent upon building demonstration plants which are broadly similar to CDFR, why not wait and license from them when their designs are proven? After all, other countries have acquired the ability to build thermal nuclear reactors on the basis of foreign licences, whilst Britain has spent untold sums in developing indigenous reactor designs. Alternatively, why not collaborate with France and Germany, learning through participation, so as to be able to incorporate any necessary modifications in an eventual British version? The argument that Britain must go it alone because we have little to offer in such collaboration hardly squares with the oft-repeated claim that Britain leads the field in fast reactor technology.

Third, given the decisions to build two further advanced gas cooled reactors (involving considerable design modifications) and to undertake the design work necessary for a pressurised water reactor, how will it be possible to proceed with CDFR without severely overstretching the design engineering resources of the ailing nuclear industry?

So far, attention has focused on the question of whether CDFR should be built, rather than what happens if it is not built. Fast reactor work accounts for two-thirds of the scientists and engineers employed by the UKAEA on reactor development. A decision not to build CDFR will immediately call into question the future of the UKAEA. Even if CDFR is approved, this question cannot be ignored indefinitely. Sooner or later, it must confront any single-mission R&D agency. It has already been faced in the USA, where the Atomic Energy Commission was amalgamated into ERDA and now into the US Department of Energy. In Ontario, the Royal Commission on Electric Power Planning, under Dr Porter, has recommended that the Canadian nuclear R&D establishment should become an energy R&D agency.

It is true that the UKAEA has partially diversified into ancillary work; but I would like to think that its skills and resources, which are unique in Britain, can be applied on a much larger scale to other technologies with the same brilliance and dynamism that were applied to nuclear technology in the 1950s. This is not to suggest that the UKAEA must become an energy R&D agency. Its new role must be defined in the context of overall industrial and R&D strategy and the need to make the best use of all our public laboratories.

The assurance of a future rôle which is nationally and personally worthwhile will remove much of the uncertainty for the scientists and will make it less likely that a breeder is built for the wrong reason. □

'Saving it' is easier said than done

With the oil crisis in full cry and nuclear energy still an uncertain option, the UK government this week called on industrialists to make energy saving a priority. **Paul McDonald** assesses the potential of this new policy.

Energy conservation, according to Mr David Howell, the Secretary of State for Energy, is "now at the centre of energy policy". Faced with the task of trying to cut oil consumption by five per cent, the Government is relying heavily on industry to make significant improvements in the efficiency with which it uses its energy. However, apart from the widely publicised efforts of certain individual companies, there has been little progress in this sphere.

There are no major technical reasons why much of industry could not improve the efficiency of its use of energy substantially. Such is the inefficiency of the average industry, that its energy can usually be reduced by 10% with little or even no capital investment, simply by goodhousekeeping measures, such as insulation, or turning off machinery not in use. Savings of a further 10% are usually possible from improvements in processes; and a further 10% on top of that from major reorganizations of processing and wholesale re-equipping. The actual proportion that can be saved varies from industry to industry. The Department of Energy's estimates of potential savings vary from a total of 10% in the pottery industry to 61% in aluminium smelting.

The Department of Energy has, unfortunately, no way of assessing accurately how industry is progressing in this. The most optimistic estimates put the average level of improvement in the efficiency of industrial energy consumption since 1974 at 10%; but this is no more than could be achieved by general goodhousekeeping measures in most industries — and certainly below the level of our overseas competitors such as West Germany and Japan. In spite of an upsurge of interest in energy conservation amongst industrialists since January, there are still many factors inhibiting any major improvement in the use of energy, which are going to make the Department's target of 5% very difficult to achieve.

On the surface, there appears to be a good deal of activity: over 4,000 energy managers have been appointed; but their functions and responsibilities vary enormously, and, even in some large companies, a number of them are little more than token appointments.

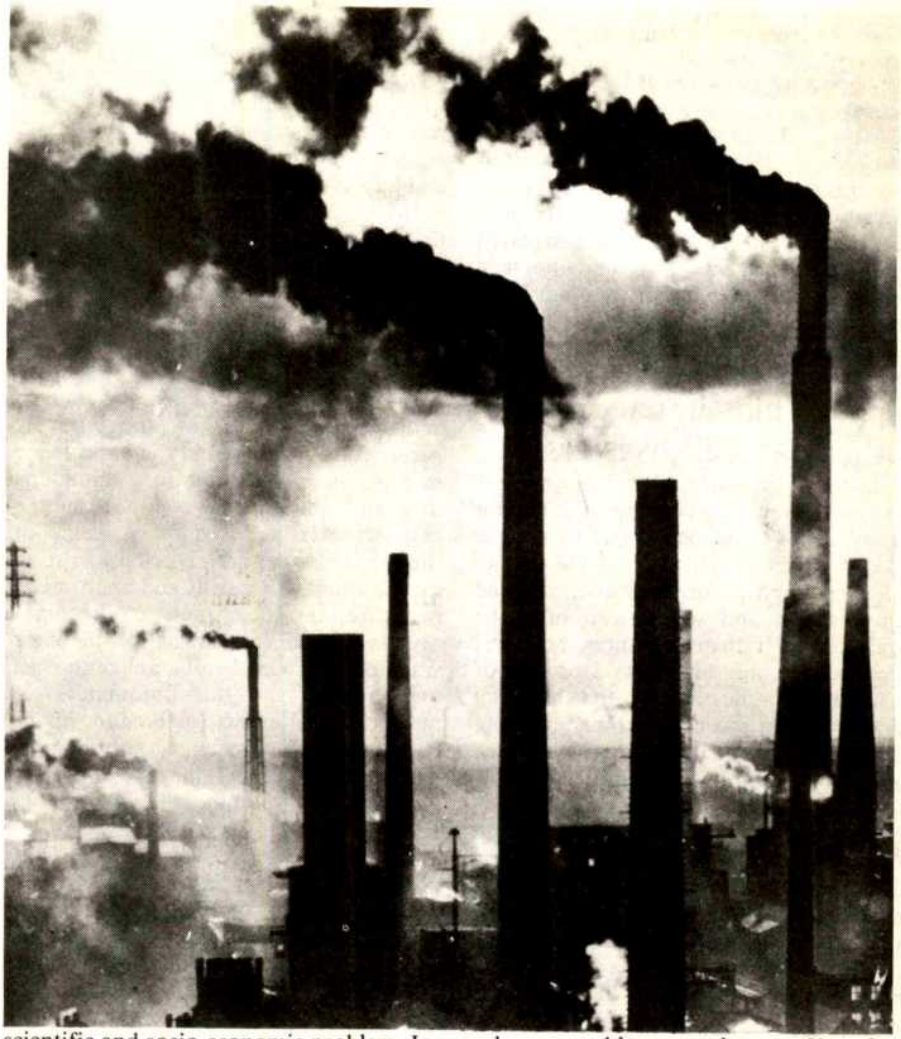
A major constraint on improving energy efficiency is the lack of capital for measures designed to improve energy use, such as waste heat recovery and improving processes. This is particularly the case for the large number of industries where energy accounts for less than about 2% of manufacturing costs. There is, in any case, a preference in most industries to invest in production rather than conservation. Whilst the latter brings savings, these do not necessarily show up in reduced expenditure on energy in subsequent years, since they may easily be cancelled out by the general rise in energy prices. Given the preference for increasing output, conservation measures are often penalised by the imposition of shorter payback times than those for other items of capital expenditure.

Continuing economic recession and low levels of productivity greatly inhibit the efficient use of energy by forcing industries to work well below their full capacity. Furthermore, in a number of industries, such as food, drink and tobacco, there is a trend towards increased processing, which will increase the consumption of energy for the same level of output.

Improvements in energy use are further hindered by the slow rate of re-equipping in British industry. Many companies wait until equipment is due for rebuilding or replacement before trying to improve its energy consumption. In the case of a furnace, this is only once every 5-10 years.

Proper records of fuel consumption are vital to the sucess of any serious attempt to improve energy efficiency. In a great many companies these simply do not exist, making it impossible to set targets or monitor progress. Futhermore, the high costs of installing and maintaining adequate metering for this task will make the accurate control of energy use a continuing problem for a large number of firms.

The aim of company energy policies is not always to save energy. For certain firms operating continuous processes, security of supply may be the paramount consideration. For others, energy policy may be part of a general cost cutting exercise, and can just as easily involve renegotiating tariffs or switching to other fuels, as actually trying to reduce consumption by requiring the installation of energy using anti-pollution equipment as part of its health and safety policies. Energy conservation is clearly not going to be the easy part of the Government's energy policy.



Dr McDonald is a writer on energy matters

A political view of CO_2

The increase in atmospheric carbon dioxide may be accelerated by President Carter's new-found enthusiasm for synthetic fuel. But the atmospheric 'crisis' may come too slowly to bother the politicians, argues **Michael Glantz.**

FOR those interested in the study of climate — including its impact on society and society's impact on it — 1972 was an extremely important year. In that year a collection of weather anomalies occurred adversely affecting global food production and therefore availability. At that time some blamed the food shortages on the weather. More recently, however, those claims have been reevaluated and the blame is being apportioned more correctly between weather and society. The anomalies of 1972 included the fourth consecutive year of drought in the Sahelian zone of West Africa, the failure of the Peruvian coastal fisheries, droughts in Central America, the Soviet Union, India and China, along with excessive rains in parts of the Philippines, Australia and Kenya.

At that time the sharp increase in grain prices on the international market, the largest grain purchase by the USSR to that date, and the general scarcity of foodstuffs in the international marketplace, were all blamed on fluctuations in the weather and led to the concern that the weather had gone haywire. Concern about what was happening to the weather can be evidenced by citing such publications as "Ominous changes in the weather," "What's gone wrong with the weather?", "When the Sahel freezes over," The Cooling, Blizzard, Ice, The Genesis Strategy, Hot House Earth, Climatic Change, The Weather Conspiracy and so on.

Was the climate regime getting cooler? Was it getting warmer? Was it staying the same? Was climate variability increasing? Climate (and weather) have become recognised as important variables in the activities of societies, regardless of the level of industrial development, geographic location, or ideological bias of the respective society. This new-found importance is due partly to the media's acceptance that such factors are newsworthy, and partly as a result of the raised consciousness of some political and economic leaders that climate factors must be considered in the food-population equation.

A projected CO_2-induced global warming became part of the debate and is increasingly being viewed as an important scientific and socio-economic problem. In addition to the natural processes, CO_2 enters the atmosphere as a result of human activities, primarily the burning of fossil fuels. The current rate of increase of CO_2 content in the atmosphere has been measured at about several tenths of one per cent per year. With projected energy use increases it has been suggested that a doubling of the CO_2 content in the atmosphere can be expected by the middle of the 21st century.

A doubling is expected to warm the lower atmosphere (as a result of various physical processes) with estimates ranging from 1 to 4 °C.* This warming is expected to affect weather patterns and climate regimes around the globe, changing precipitation and temperature patterns resulting in the shifting of agricultural zones. Such shifts would adversely affect some regions while favourably affecting others, with no assurances as to who the winners and losers will be. Thus, much attention has been focused on the ultimate effects of the increased CO_2 loading of the atmosphere.

In fact, the increase in the CO_2 content of the atmosphere takes place each day and, measurably so, each year. Yet, the annual increments are perceived by most observers to present little immediate danger to society and are considered non-threatening. No immediate attention, let alone rectification, of the CO_2 problem is perceived to be necessary.

The CO_2 impacts are especially an important area of study for the social sciences because they represent, as well as highlight, a relatively new (some would say neglected) research area of interactions between climate and society. Many consider the study of the CO_2 content of the atmosphere timely even though it is still only a potential problem with what appears to be a relatively long lead time, that is, the major impacts are projected in terms of decades. The "luxury" of a long lead time is not accepted as such by everyone, since society will require a long time to make adjustments that would be in line with attempts to develop alternative sources of energy to reduce the use of fossil fuels.

It may be useful to separate the CO_2 problem in to the two predominant perspectives: as an event — the doubling, and as a process — the annual 1 p.p.m. increase. In reality both views are correct but each by itself presents an incomplete picture of the problem. To better understand and, therefore, deal with the potential societal and environmental

*It is important to keep in mind that the locations, types, magnitudes and directions of change as well as the importance of certain variables in CO_2-related processes are in most instances educated speculation at this time.

0028-0836/79/290189-02$01.00

Macmillan Journals Ltd 1979

problems associated with an increased CO_2 content of the atmosphere, the problem must be viewed as both event and process.

Most of the attention of the media, the public and the policy-makers is directed toward the CO_2 problem as an event because of the spectacular aspects of a CO_2 doubling. For example, an often referred to impact of a doubling is a surging into the ocean of the West Antarctic Ice Sheets resulting eventually in an increase in sea level on the order of 5-8 metres.

Spectacular impact of other natural disasters

The CO_2 problem viewed as an event has been likened to other specific natural disasters — earthquakes, droughts, floods, severe or dry winters. The impact of a drought, for example, on the environment and society can often be spectacular. In many instances, however, the drought only highlights a process of environmental degradation that has been under way for a period of time preceding the drought event itself; a process which at any one point in time represents only a low level abuse of the environment.

So, the dust storms in the American Great Plains during the droughts in the 1930s and briefly in the 1970s, while spectacular, were not unique (except for their magnitude). Each year during the period between such major drought events, the top soil was also blown away at a much less spectacular level. The cumulative effect of such storms in the interdrought periods may in fact be much greater than that of the specific drought event.

One might argue by analogy that the tendency to overfocus on the more spectacular event (the CO_2 doubling) takes place at the expense of attention to the slow but steady annual increases in CO_2 (the process).

The example of urban air pollution, as a low-level but continually increasing insult to the environment, in some ways represents a microcosm of the CO_2 problem as a process. It also suggests how society might react to such a problem. There are very gradual, but definite, changes that take place in the environment (especially weather and climate) as a result of urban air pollution, a large part of which results from the burning of fossil fuels.

Yet, in many instances the changes that have occurred are low level and have apparently taken place gradually over an extended period of time. One might ask, how well have societies and their political leaders dealt with those incremental changes in air pollution levels and with the social changes they may have brought about? How well have they dealt with drought episodes? How well can they be expected to deal with CO_2 problems?

Studies of societal responses to spectacular events such as major droughts and their impacts suggest that political interest in those kinds of problems varies with the presence of other problems that compete for time and scarce resources. In addition, interest in such events also rises and falls as a result of the different lengths in office of different decision-makers (2,4,6 year cycles for politicians). This fluctuation in interest in manifested in a relatively abrupt swing between two types of decision-making processes:

- "crisis management" and
- "muddling through."

In crisis decision-making, the time to act is perceived to be short, the stakes are perceived to be high, and the impacts are seen to be severe. As for "muddling through," the opposite is seen to be the case; there is perceived to be plenty of time to act, society is expected to rise to the occasion with a swift and appropriate response if and when it becomes necessary, and the impact of the next situation is expected to be unlike the last one because of the uniqueness of meteorological events (or because of the belief that society tends to learn from its past mistakes), or as is the case of a CO_2-induced global warming, the situation has never happened in the past.

The two perspectives of the CO_2 problem mentioned earlier — event and process — are useful for a better understanding of not only the problem and its impacts but of the political decision-making responses to it. For example, perceiving the increase in CO_2 levels as an event may be valuable for creating an awareness of the potential consequences. It may also be helpful in generating public and political concern about the risks associated with a continued dependence on fossil fuels. However, if the analogy of urban air pollution as a microcosm of the CO_2 problem is accepted, then it can be seen that spectacular arguments about the CO_2 doubling will not bring about the desired public policy decisions concerning alternative energy systems.

Muddling through on long-term problems

What is needed is a decision-making approach that matches the environmental situation. While the concern with a doubling might initially create a crisis decision-making atmosphere, it would be an ineffective approach to an environmental problem which is essentially low level but cumulative, a not so spectacular problem that requires sustained interest over a long period of time.

In the past the decision-making approach to low level environmental problems such as air pollution has generally been one of muddling through. That may have been adequate in dealing with some political and social problems, but it has not been an effective way to deal with low-level cumulative environmental problems. Eventually such problems increasingly worsen until a crisis situation is perceived to prevail. Then policy making grows out of crisis management.

Crisis decision making from the outset has also been ineffective as a way to deal with low-level cumulative insults to the environment. After a brief flurry of decision-making in a crisis atmosphere, the crisis (perceived high threat, short time to act, high cost) in this case does not immediately materialise. As a result, interest in the problem dissipates and those who again attempt to generate interest receive little response from the media, the public and the politicians. Environmental degradation, however, continues to worsen steadily.

Crisis thinking may be the only way

What is needed is a way to deal with the two aspects of the CO_2 problem simultaneously. The CO_2 problem, not unlike the more localised urban air pollution problem, might be seen as an "impending" crisis and, therefore, in need of a special type of decision-making process, one that combined the positive elements of a "crisis awareness" with cautious decision-making.

An interesting question that arises is whether a democratic society can effectively deal with a CO_2-like environmental problem. Of the competing interests in such a pluralistic society, some of those interests will be winners and some will be losers. The demand of society for continually increasing amounts of energy derived from the burning of fossil fuels may be more immediate and pressing than the environmental effects of such activities. In addition, in every society where resources are scarce, there is a great competition among interest groups for attention, time, and resources to deal with their particular problem. In light of the hydra-headed crises that confront most societies (water, food, population, energy, disease, etc.) interest in any one problem (especially the low level ones) lasts only for a short time before society shifts its attention to the other problems that confront it. So it is possible that a pluralistic society may best be equipped to deal with environmental problems on a crisis basis, that is, it is best (if not only) capable of fighting brush fires as they arise.

The question then becomes one of developing a policy-making approach for a pluralistic society (including the international community), one which can sustain the interest and concern of various segments of society in a low-level but cumulative environmental problem such as the effects of the continually increasing burning of fossil fuels. □

Longer perspectives in neutrino physics

from D. J. Miller

THE honeymoon is drawing to an end. The charms of the 'new physics'—weak neutral currents, the J/ψ, the upsilon, parton-like scattering and jets — are now part of the everyday world. At the Bergen conference 'Neutrino '79'* this change of outlook showed in a number of ways.

J.D. Bjorken (Stanford Linear Accelerator Center) summarised the situation. A year ago individual experiments, such as the Gargamelle neutrino-electron scattering result (see *News and Views* **273**, 98; **274**, 531; 1978) looked as if they might change our whole understanding of the field. But as such fluctuations are superseded by accumulating statistics, the 'standard model' has shown great elasticity. The same picture always reasserts itself. The strongly interacting particles (hadrons) are explained very economically in terms of fractionally charged 'coloured' quarks, fundamental particles at the same level as the leptons (electron, muon, tau and the neutrinos), but confined in threes or in quark-antiquark pairs. The electromagnetic and weak couplings of quarks and leptons have settled into a simple pattern. Last year's questions were about the neutral weak currents. This year three theorists stood up one after another (J.J. Sakurai, University of California, Los Angeles, P. Langacker, University of Pennsylvania and M. Roos from Helsinki) and, with a variety of starting assumptions — discarding part of the data, varying the theoretical model, fitting 10 parameters, 7, 5, 2 or 1 parameter — they all came back to the same values for the couplings. There is still a lot of checking to be done, but many of the experimental reports on neutrino results from accelerators are beginning to sound routine.

All theoretical discussions of the immediate experimental picture are dominated by the two gauge theories which together now constitute the standard model; QCD (quantum chromodynamics, see Marciano and Pagels *Nature* **279**, 479; 1979) for the strong interaction with quark-binding, and $SU(2) \times U(1)$ (the 'Glashow-Weinberg-Salam model', see *News and Views* **279**, 675; 1979) for the weak and electromagnetic interactions. Neither of them is proved to be correct but each offers an economical and comprehensive explanation of a large group of phenomena. Neutrino results which test the predictions of QCD were reported by a number of groups and it is clear that the breakdown of the simplest quark-parton model of neutrino or muon scattering is consistent with QCD. A few results, notably some new muon scattering data from Fermilab experiments, did not quite fit in — but people were inclined to wait and see whether such disagreements would just go away, as so many others have done.

Two working gauge theories would seem to imply an underlying unified gauge theory. 'Grand unified models' are being put forward with increasing confidence — the simplest being the SU(5) theory due to Georgi and Glashow. The reaction to such models last year was lukewarm. How could we test a unified theory when the forces it describes (strong, weak and electromagnetic) only become equal at an energy of around 10^{15} GeV? Now, however, it has been realised that an important experimental test lies within easy reach. The credit for pointing this out belongs, among others, to Cecilia Jarlskog of Bergen — chief organiser of the conference and a uniquely good-humoured review-speaker. In her talk she reminded us that if the 'grand unification mass' is 5×10^{14} GeV then the proton lifetime should be between 10^{30} and 10^{33} years (see *News and Views* **278**, 687; 1979). Experimental limits on this lifetime are already more than 10^{29} years — a by-product of cosmic-ray neutrino experiments. The most interesting experimental session of the conference to me was the one which contained no new results at all but in which L.R. Sulak (Harvard University) and E.C. Fowler (Purdue University) talked about plans for experiments to push the limit on the proton lifetime to beyond 10^{33}, perhaps even to 10^{35} years. Sulak presented a scheme which is likely to be working within a year. It involved no new technology — just a tank of water 20 m × 20 m × 20 m, with a grid of photomultipliers over all of its faces to detect Cerenkov light from the electromagnetic showers which would be produced by such decays as proton → positron + pi-zero.

The implications of the new physics, in particular those of the neutral weak currents, are now being worked out in other fields than high energy particles. An important series of experiments is taking place on the quantum-optical effects of parity violating couplings. E.D. Commins (University of California, Berkeley) reported that the Novosibirsk result on parity-violating optical rotation in bismuth vapour is looking increasingly secure and is agreeing with the $SU(2) \times U(1)$ model predictions. He presented his own preliminary but positive results on dichroism in thallium and he suggested that the null results seen by some groups working with bismuth may have been due to such subtleties as variable side-bands in their laser beams. The present motivation for all such experiments is still to check the weak neutral current couplings, but I wonder if this is not likely to become a 'spin-off' field from particle physics, comparable to the 'spin-offs' of the Mossbauer effect and nuclear magnetic resonance from nuclear physics. Perhaps in a dozen years optical parity-violating effects will be another tool in atomic physics or in chemistry; the apparatus is not expensive and laser technology is advancing rapidly. Low energy nuclear physicists are also now joining in the search for neutral-current effects and some positive results were reported.

But astrophysicists provided the widest horizons. There is still a problem in the observation of neutrinos from the Sun. M.S. Davis's group from the Brookhaven Laboratory see about one-half or one-third of the predicted rate of transitions $^{37}Cl + \nu_e \rightarrow {}^{37}Ar + e^-$. This reaction is only sensitive to higher energy neutrinos which come mostly from a subsidiary branch of the solar nucleosynthesis cycle. For years there has been a debate as to whether the solar models, the nuclear transition rates or the properties of neutrinos were to blame for the anomaly. Now a new collaboration has been formed — reported by Kirsten from Munich and including Brookhaven,

* 'Neutrino '79' was held in Bergen on 18-22 June and organised by the University of Bergen and NORDITA.

D. J. Miller is in the Department of University College, London.

0028-0836/79/290191-02$01.00

Pennsylvania and the Weizmann Institute, which will look for the more copious lower energy neutrinos that must be produced by the basic solar hydrogen-burning process $p + p \rightarrow d e^+ \nu_e$. They will collect 50 tons of gallium over the next few years and search for the expected production of one atom per day of radioactive germanium by way of the process $^{71}Ga + \nu_e \rightarrow {}^{71}Ge + e^-$.

Other astrophysicists reported on the apparent regress of the theory of stellar collapse. This has followed from a serious treatment of the equation of state of highly condensed matter. It had been thought that neutrinos could provide the mechanism for transporting energy from the core of the supernova to the exploding envelope, thus allowing the collapsed core to get rid of its binding energy and form a neutron star. But present values for neutral and charged current cross-sections require that during the crucial last second of collapse the neutrinos are trapped in the core and form yet another degenerate Fermi gas, in equilibrium with neutrons, protons, electrons and nuclei. As a consequence of this, a number of speakers reported, it is not now possible to show how a supernova envelope can be formed by the collapse of a massive star. New ideas and calculations are clearly needed, but the theorists are hampered by a poverty of experimental constraints. Supernovae are seen only about once per century in our Galaxy and no one has yet observed the expected 'neutrino flash' that should go with the visible flash. Such an observation would be extremely useful.

The biggest accelerator of them all, the primaeval big bang, provides the most speculative field of application for the new physics. Cosmologists, D. Schramm (University of Chicago) told us, have embraced the Grand Unified models as a potential answer to the question of why the universe seems asymmetric in baryon number. Why is all stable matter apparently not matched by equal amounts of antimatter? If the massive (10^{15} GeV/c^2) particles exist which would mediate proton decay they must have been produced copiously in the very earliest stages of big bang. Their decays could be affected by substantial CP symmetry violation, leading, as in K° processes, to a time asymmetry in the production of positive and negative particles. In thermodynamic equilibrium, such effects would be cancelled out, but in an expanding and cooling system an overall baryon excess over antibaryons might well be produced. Variations on this theory have been suggested, involving such contracting mechanisms as a 'foam' of mini black holes or supercluster-sized zones of baryon and anti-baryon matter caused by local differences in spontaneous symmetry-breaking.

In the final sessions Glashow (Harvard University) gave his customary shopping list of work still to be done. Despite the widening influence of recent results, there are many gaps in our understanding. In particular, why do we have the same sort of family of quarks and leptons three times over? Why is each generation so much heavier than the last? How many more generations are there? (If more generations mean more massless neutrinos then the cosmologists cannot account for the amount of helium in the universe). Accelerator and storage-ring physics may spend the next few years tidying up at the present level of understanding but we should be building new machines at the same time. The CERN $\bar{p}p$ collider, the Isabelle pp collider at Brookhaven, the suggested European LEP e^+e^- machine and an electron–proton collider are all needed if we are to penetrate into the world of gauge bosons which promises to exhibit a rich variety of phenomena, as well as leading us closer to a unified model. Though, as Glashow reminded us, gravity should also be included before we have the truly 'Grand' unified theory. □

Recognition, restriction and immunity

by Miranda Robertson

THE immune response of animals is controlled by two sets of genes: the immunoglobulin variable region genes (V genes) which determine the responses of lymphocytes to antigens; and the major histocompatibility complex genes (MHC genes), which determine their responses to one another. It is now clear that while B cells see antigen *per se*, by means of surface immunoglobulin coded by V genes, T cells see antigen only in association with the appropriate syngeneic MHC determinant, and it is this combination that induces the helper, suppressor or killer response. But whereas the molecular basis of antigen recognition by B cells is well understood, that of T cells has remained elusive. The attempt to define at the molecular level both what T cells see with, and exactly what they see, was therefore one of the main preoccupations of participants at a recent meeting on recognition and function in T and B lymphocytes.*

One crucial question is the contribution of the V genes to T cell recognition. Eichmann and Rajewski, and Binz and Wigzell have provided strong circumstantial evidence for the expression of V genes in T cell receptors with the demonstration that both helper and suppressor responses to specific antigens can be induced by antibodies against V-gene coded antigenic determinants (idiotypes)[1,2]. This is important not only for the light it sheds on T cell receptors, but also because it implies in principle that T cells as well as B cells may be subject to anti-idiotypic control as proposed in Jerne's network theory (reports of whose demise[3] are greatly exaggerated).

More recently, D. Givol (Weizmann Institute) has raised antisera in rabbits that react with framework determinants of V_H chains of mouse immunoglobulin[4]. These antisera will prevent the binding of antigen to some T cells and inhibit T cell help *in vitro*, and have recently been exploited by T. Tada (Tokyo University) in the characterisation of an antigen-specific suppressor factor isolated from a T cell hybridoma[5].

Soluble factors derived from T cells have been the focus of much recent investigation on T cell functions. It is not yet clear how they are related to the T cell receptor: they may, by analogy with surface and secreted immunoglobulin on B cells, be a secreted version of the membrane receptor; or they may be the receptors themselves, shed into the culture medium *in vitro* but with no normal function as a soluble molecule *in vivo*.

The data from Tada's laboratory strongly suggest that the T cell receptor and the soluble factor are very closely related, and that they are determined both by immunoglobulin V genes and by genes in the I region of the MHC. The basis for this conclusion is that antisera against 'I-region-associated' (Ia) antigens, as well as anti-V_H antiserum and specific antigen can all bind both to suppressor T cells and to the antigen-specific suppressor factor. A further extremely important point is that the Ia antibodies are specific for the mouse strain that donated the suppressor cell, and the factor acts only on cells from mice with the same I-J antigens. This so-called restriction by MHC antigens is characteristic of T cell interactions and it is therefore important to know whether it applies to soluble factors.

An important issue which hybridomas should help to resolve is that of the part played by antigen nonspecific factors in lymphocyte interactions. Although there have been many reports of such factors, some feel that such nonspecificity in a system whose principal characteristic is exquisite specificity must make their functional relevance suspect. Others, including Tada, have incorporated them into hypothetical nets in which both specific and nonspecific factors play a part, acting on different subsets of cells. Tada's laboratory has developed a number of hybridomas, some producing specific and some nonspecific suppressor factors. The fact that the nonspecific factors are

*The ICN-UCLA Symposium on T and B Lymphocytes — Recognition and Function, was held at Keystone, Colorado, on 26-30 March.

0028-0836/79/290192-02$01.00

© Macmillan Journals Ltd 1979

monoclonal eliminates the possibility that their nonspecificity is apparent rather than real, and that the cells are really producing a very large number of different specific factors.

A similar collection of hybridomas producing helper factors would be a great asset. The biochemical elucidation of helper factors lags well behind that of suppressors. There is now evidence for idiotype-bearing, antigen-specific factors which replace T cell help in the production of antibodies against phosphorylcholine (M. Feldman, University College London) and (T,G)-A--L (ref.6) but the relationship of such specific factors to nonspecific helper factors remains unclear. J.D. Watson (University of California at Irvine), for example, reported that T cell growth factor(s) from supernatant of spleen cells treated with concanavalin A would act both as a nonspecific growth factor and as a nonspecific helper factor in antibody production or the generation of cytotoxic T cells; but if microcultures of ten or so cells are expanded with the use of the growth factor, their supernatants are active only on some cells. This experiment, which is similar to that of Waldmann and Lefkowitz[7] suggests that 'nonspecific' growth factors from concanavalin A supernatants may be mixtures of antigen or idiotype-specific factors; it remains to be seen whether such mixtures include a genuinely nonspecific T cell growth factor.

MHC restriction, which limits T cell recognition of viral antigens to infected cells bearing the same MHC antigens, can be seen as a special case of antigen specificity applied to T cells. It has now become clear that, like any other kind of antigen recognition, MHC restricted recognition is subject to cross-reaction. Cross-reactions have been demonstrated in experiments in which allogeneic virus-infected cells are killed by cytotoxic cells depleted of alloreactivity by passage through the appropriate mouse strain (J.R. Bennink, University of Philadelphia). The cross-reaction may not be reciprocal: for example, b haplotype cells may kill infected k haplotype targets while k cells will not kill infected b targets[8].

The converse can also occur: certain combinations of haplotype and virus can fail to elicit a cytotoxic response even when MHC restriction requirements are met. Much of the interest in such failures of recognition is of course due to their possible bearing on susceptibility to disease in man. A McMichael (Oxford University) reported that human lymphocytes of certain haplotypes will not show MHC-restricted killing in association with influenza virus antigens, whereas others do. Similarly, S. Shaw (US National Institute of Health) reported that some HLA haplotypes elicit much stronger anti-influenza cytotoxic responses than others.

Miranda Robertson is an Associate Editor of Nature.

0028-0836/79/290193-02$01.00

These data lend support to the proposal that the immense polymorphism of the MHC antigens is due to the massive selective advantage of heterozygosity: if the combination of one parent's MHC antigen and virus does not elicit a response, the other parent's may (indeed this has been shown[9]).

However, this begs the question of why antigens that fail to elicit an immune response should survive in the population. The answer may lie in the mechanism of selective recognition. It is now clear that some combinations of MHC antigen and virus cross-react with alloantigens[10]: it is thus highly likely that the combination of some viral antigens with self antigens will cross-react with other self antigens. Since any cell reacting strongly against self must be eliminated, it follows that cells reacting against certain combinations of self and virus will sometimes be eliminated too.

While it is clear that to avoid autoimmune reactions T cells with high-affinity receptors for self must be eliminated, it has been suggested that receptors with weak affinity for self antigens are the basis for MHC restricted recognition [11]. Tentative evidence in support of this theory was presented by H. Wigzell (Uppsala University), who has used an anti-idiotypic serum raised against immune T cells specific for an allogeneic antigen to extract the T cell receptor for that antigen. He then labelled internally the allogeneic antigen, the self antigen of the immune rat and a third-party antigen, and ran them on Sepharose columns to which the receptor was bound. Three labelled polypeptides from the third-party control passed straight through the column; two chains from the cells of the immunising strain were stopped; and one chain from the self strain was retarded.

Wigzell interprets this as evidence not only for weak binding of alloreactive receptors to self, but also as evidence that different polypeptides are involved in the recognition of self MHC and allo- or viral determinants. It is still a matter of disupte whether T cell receptors 'see' virus and MHC antigen as a complex, with only one receptor for both ('altered self'), or whether they see the two antigens with different receptors ('dual recognition')[12]. Attempts to resolve this question at a cellular level are all open to doubt: it is probable that only biochemistry can produce the answer, and Wigzell's experiment may be a first step. □

Ecology of photosynthesis

from Peter D. Moore

Resource partitioning in plants is less well documented than among animals and this is not surprising, for the resources on which plants depend are fewer and adaptations which could be referred to as partitioning are generally more subtle than is the case with animals. This is probably why plant ecophysiologists have eagerly grasped the opportunities presented by the gradual exposition of the extent of the C_4 and crassulacean acid metabolism (CAM) photosynthetic adaptations among plants. It is well established that both of these modifications to the basic C_3 Calvin photosynthetic system are associated with certain ecologically selective advantages in conditions of high temperature, high light intensity and water stress. This has led to many investigations into the biogeographical significance of the adaptations, mainly by mapping their distributions on a continental scale (see *Nature* **272**, 400; 1978). Information is now accumulating concerning the ecological value of such adaptations in the local composition of plant communities.

To search for correlations between the success of one particular type of photosynthetic system and an environmental gradient, such as aridity or elevation, is not new. In 1974, Mooney, Troughton and Berry (*Carnegie Inst. Ybk.* **73**, 793; 1974) reported a survey they had conducted along the coastal strips of California and Chile, where the climate shifts from a Mediterranean to a desert type with decreasing latitude. They found in both locations that increasing aridity was associated with an increasing proportion of CAM plants in the flora. Among C_3 plants, there was a change from evergreen to drought-deciduous forms, but C_4 plants were virtually absent from all stations. They explain this as a consequence of the low temperatures prevailing at the times of water availability.

More recent work in the cold winter deserts of Utah by Caldwell, White, Moore and Camp (*Oecologia, Berl.* **29**, 275; 1977) has also shown that such C_4 species as *Atriplex confertifolia* fail to achieve many of the advantages normally associated with the C_4 system when they commence growth in the cool of spring. They may, however, still match the growth of their C_3 competitors and gain the advantage of a longer growing season as summer aridity sets in. It is difficult, therefore, to explain the lack of C_4 species in the Californian and Chilean coastal deserts.

Eickmeier has now published the results of a similar environmental gradient study from Texas (*Photosynthetica* **12**, 290;

Peter D. Moore is a Senior Lecturer in the Department of Plant Sciences, King's College, London.

1978). Of 88 non-herbaceous species found along a 1,300-m elevation gradient, 22 were CAM, three were C_4 and the remaining 63 were C_3. Ten samples were taken at 150-m altitude intervals; density, frequency and area cover values were used to determine an importance value for each species at each elevation. The main peak in the importance of CAM species was found to occur at low altitude, that of C_3 species at higher altitudes and the C_4 peak was intermediate between the other two. Eickmeier considers this sequence to reflect both the adaptational significance of the physiological variations and also the respective responses to biotic, competitive factors. For example, the CAM plants are most suited to the low altitude, arid environment, where competitive interplay with other plant species may be regarded as minimal (but see *Nature op. cit*). C_3 plants, he claims are evolutionarily attuned to competitive situations with low abiotic stress; C_4 plants can cope with both, having potentially high productivity and the capacity to withstand water stress.

The greater competitive success of C_3 species in higher altitude, more mesic conditions in the tropics has now been demonstrated by Tieszen, Senyimba, Imbamba and Troughton (*Oecologia, Berl.* **37**, 337; 1979) along an altitudinal and moisture gradient in Kenya. They have found that nearly all the grass species of the low altitude grasslands in Kenya are of a C_3 photosynthetic type. Some grass tribes, such as Paniceae and Andropogoneae (both exclusively C_4) were most frequently encountered at intermediate altitudes. The exclusively C_3 tribes (such as Festuceae, Aveneae and Agrostideae) were found only at high altitude. No C_3 species were found below an altitude of 2,000 m and no C_4 species above 3,000 m.

Evidently the complex adaptational significance of C_3, C_4 and CAM photosynthetic systems is profoundly influential on the floristic composition of plant communities both on a biogeographic and an ecological scale.

Viral pathogenesis and virulence

from D.A.J. Tyrrell

IT is easy to say "The influenza virus causes influenza", while having really no scientific explanation of many of the signs and symptoms of the disease, for instance the headache or the depressed white blood cell count. This meeting* would have jolted anyone out of such a complacent view and also gave some good examples of how patient, thoughtful research is building a more complete picture of what happens in some virus infections – how the virus enters and spreads through the body, enters cells, disturbs their function, interacts with the host defence mechanisms (such as interferon or humoral or cellular immunity) and disturbs normal body functions to produce what we recognise as a clinical disease.

What seem in the laboratory to be very similar viruses may nevertheless produce either different diseases or similar diseases by different methods. There was for instance a session on coronaviruses, which all look the same and are similar in biochemical composition. Yet the different coronaviruses are specific to particular species — mouse coronaviruses never seem to affect man or *vice versa*, for example — and sometimes even to a very limited variety of cells in one species. P.A. Bachmann (World Health Organization, Munich) described how the coronavirus of transmissible gastroenteritis of pigs (TGE) affects only the differentiated enterocytes of the villi of the small intestine which may almost disappear. The crypt cells, however, survive and migrate up to cover the villi again, but while they are doing this and differentiating into mature enterocytes, there are profound physiological disturbances — lack of absorption, excess secretion, lack of digestive function (for instance the splitting of lactose by disaccharidase) — leading to marked diarrhoea, which can kill a piglet from dehydration unless it is treated. On the other hand, another pig coronavirus causes vomiting and wasting disease. M. Pensaert and K.L. Andries (State University of Ghent) described how this virus affects the upper respiratory tract and lung, the tonsil and the jejunum; it affects the cells of the plexus of Auerbach and Meissner in the gut and seems to spread from them. It spreads through the nervous system to the brain stem and later to the spinal cord and the rest of the brain. All this was established in great detail by painstaking serial virus assay and immunofluorescent microscopy of experimentally infected animals. This suggests how the disease develops — probably the virus spreads from the respiratory tract and gut along peripheral nerves to the brain stem where the lesions give rise to vomiting, while the damage to neurones in the plexuses prevents normal peristalsis, leading to wasting. Furthermore, knowing that the virus invades the nervous system widely, it is not surprising that a virtually identical virus has been recovered from pigs diagnosed as having encephalitis, and so was named haemagglutinating encephalitis virus.

Explanations of these important and mysterious tropisms of viruses must lie at the molecular level, in the functioning of the peptides and nucleic acids of which viruses are made. B. Fields (Harvard Medical School) gave an example of what can be done, when he described his study of two pairs of genes, represented by the RNAs S1 and M2 of reoviruses types 1 and 3. He studied parent viruses and a collection of recombinants (or reassortants) and showed that S1 nucleic acid specifies the haemagglutinin protein of the virus and that this is responsible for the ability to agglutinate red cells and for serological specifity. It is also responsible for cell tropism in the animal, so that the type 3 virus causes a necrotising encephalitis due to a specific attack on the neurones. It also determines the extent to which the virus inhibits DNA synthesis when absorbed to cells. M2 RNA on the other hand, which is abundant on the surface of the virus particle determines whether the virus resists inactivation by chymotrypsin. M2 RNA from type 3 makes the virus resistant to host enzymes and hence able to infect when given by mouth. Discussion of this work showed that the next step was to determine at which site on the surface of the neurone the virus attached. This is probably a part of the chemical matrix which has some other physiological function characteristic of neurones. Reassortants were also made which were infectious when given by mouth, like type 1, and caused central nervous system disease, like type 3, and so, by the oral route, were more pathogenic than either parent. This type of manipulation confirms earlier conclusions about the functions of the genes.

It is very difficult to evaluate the way in which the host defences interact with the virus, sometimes preventing its multiplication, sometimes causing immunological damage to infected tissue. For instance, P.A. Neighbour and B.R. Bloom (Albert Einstein College of Medicine, New York) described some of their work which started when they analysed why the lymphocytes of patients with multiple sclerosis show an unusual reactivity to measles virus; they tracked down the fault to a defect in the ability of their lymphocytes to produce type 1 interferon (Neighbour & Bloom *Proc. natn. Acad. Sci. U.S.A.* **76**, 476; 1979).

The success of the meeting was obvious, and there were many other interesting papers besides those mentioned here, including whole sessions on herpes viruses and rhabdoviruses. There were clear signs that pathogenesis not only holds scientific interest, but may be a source of practically useful knowledge: vaccines and antiviral treatments do not always work – sometimes because we guess too much and know too little about the process by which viruses produce disease. □

*A symposium on Mechanisms of Viral Pathogenesis and Virulence was held in Munich on 6 and 7 June, 1979 and organised by P.A. Bachmann.

Seeing is believing in lineages

from a Correspondent

AT last a directly observed and accurate cell lineage is available for the development of one organism, the nematode *Caenorhabditis*. As reported at a recent meeting*, the lineage runs from the fertilised zygote to the completion of embryogenesis (550 cells), and then there is a gap of one or two cell divisions, which have not yet been studied, before the lineage runs directly through to adult structures. This description is now up for analysis and G.von Ehrenstein (Max-Planck Institute for Experimental Medicine, Göttingen) has isolated at least seven temperature-sensitive mutants whose maternal gene expression is necessary and sufficient for normal embryogenesis, and which eventually block development at the 'lima bean' stage. Three of these produce abnormal guts without obviously disturbing the rest of the lineage; in the gut lineage one changes the direction of a single division while the other two change the relative timing of division and migration of gut primordial cells to the interior. It is, however, unlikely that the regularity of the lineage merely depends on control of cell division rate and cell division direction for there are even more extensive cell migrations across four or five cell diameters in other parts of the embryonic lineage. Certainly there is regulation in the post-embryonic lineage for, following laser ablation of single cells, their lineage and adult structures may be replaced by neighbouring cells within an 'equivalence group' (J. Kimble, MRC Laboratory of Molecular Biology, Cambridge). It remained unclear whether the replacing cell had to repeat the lineage of the ablated cell in order to replace its adult structures because within an equivalence group it always did so. (This and related work with *Caenorhabditis* was mentioned in *News and Views*, **279**, 758; 1979.)

The masterplans in 'mosaic' eggs were certainly under attack even though there are nice sets of computer simulations which could manufacture such plans (E. Parisi, Laboratory of Molecular Embryology, Naples). P. Guerrier (Biological Station, Roscoff) reviewed his own and van den Biggelaar's beautiful manipulation experiments on the 'mosaic eggs' of annelids and molluscs and made it difficult to see how anybody could still believe in mosaicism in these embryos (for example, Bigelaar & Guerrier, *Devl Biol.* **68**, 462; 1978). The *Drosophila* egg must at least be allowed its polarities, and to go with 'bicaudal', there is now a maternal effect mutant, dorsal (*dl*), which leaves the anterior–posterior polarity intact but which lacks lateral and ventral structures (C. Nüsslein-Volhard, EMBL, Heidelberg). It may be 'all dorsal' for no dorsal midline can be detected, and in order to show formally that the laser ablation fate map was altered by this dorsal hypodermis embryo it was necessary to put the mutation on a background which reduced its penetrance so that some ventral structures were formed. The polar tendencies of the *Drosophila* egg must arise during oogenesis and E. Weischaus (EMBL, Heidelberg) has now made use of another maternal effect mutant, *fs(1)K10*, in a neat mosaic analysis of stem cell behaviour during oogenesis. This mutation is expressed as a chorion defect (allowing immediate recognition of affected eggs) but its expression is restricted to the germ line; consequently recombination induced by X-irradiation during the formation of eggs can be used to follow the behaviour of stem cells which are egg precursors. From blastoderm to pupa, the stem cells increase to about 100 and this level is maintained through egg production. This technique could be exceptionally useful for analysing the effect of characters expressed in the nurse-cell oocyte clusters on subsequent development.

Even those working on haemopoietic stem cells could now see lineage diversification with their eyes and could provide direct evidence for multipotential stem cells. G.R. Johnson (Walter and Eliza Hall Institute, Melbourne) has now picked single cells, waited for them to divide twice in isolated liquid culture, separated the four cells, found that each could form colonies which contained a variety of cell types, and thus showed that one cell could form erythrocytes, macrophages and granulocytes. The implication is that cell lineages can separate without the special cell contacts and microenvironments which are supposed to pick out and diversify stem cells; nobody could decide if the behaviour of these clones was natural or perverted. The environmental lobby made a come-back with a study of the progressive education of T lymphocytes to attack virus-infected cells. It has now been shown that the major histocompatibility complex (MHC) type of both the thymus and the 'post-thymic environment' educates cytotoxic T cells to kill virus-infected cells with similar MHC (R.M. Zinkernagel, Scripps Clinic, La Jolla).

If lymphocytes can be educated, then nerve states can be altered and stabilised. The evidence that individual post-mitotic neurones can functionally convert from adrenergic to cholinergic cells in the presence of non-neuronal cells is now convincing and P.H. Patterson (Harvard University) went on to show that this change could be prevented by depolarising the neurone. This change could be seen directly in cell culture; could it be as simple as that in the adrenergic–cholinergic switch shown by neural crest cells transplanted to different levels of the axis of developing chick–quail chimaeras? Certainly these transplants illustrate beautifully the importance of the migratory path and final location in picking out the phenotype of neural crest cells (N. Le Douarin, Embryology Institute, Nogent-sur-Marne). Depolarising a neurone in culture may mimic normal neurone activity, and chronic stimulation of the spinal cord during embryogenesis may do the same. If it does, then the stabilisation of nerve synapses on muscle during development may be shown to depend on nerve activity. The system is the posterior latissimus dorsi muscle of the chick which early in development has several synapses per fibre and of these only one remains in the adult; stimulation of the spinal cord during embryogenesis maintains multiple connections (P. Changeux, Pasteur Institute, Paris). Is this the selective stabilisation theory of nerve connections in action? □

*The meeting on Cell Lineage, Stem Cells and Cell Determination was held in Seillac on 20-24 May 1979. The proceedings will be published by Elsevier-North Holland.

Mutants of the *lac* repressor

from Alan D. B. Malcolm

As part of their study of the binding of the *lac* repressor protein of *Escherichia coli* to the *lac* operator DNA, Miller and colleagues set out several years ago to produce mutants of the repressor protein by an ingenious technique, and the culmination of their work appears in three recent papers (*J. molec. Biol.* **130**, 191, 223 & 249; 1979). Miller's approach has been to use chemical mutagens to produce nonsense mutations (where a coding triplet is replaced by one of the three 'stop' signals, UAG, UAA or UGA) in a suppressor strain which possesses a tRNA able to substitute an amino acid in place of the stop. So far it is possible to insert Ser, Gln, Tyr, Lys or Leu at UAG; Gln, Tyr or Lys at UAA and Trp at UGA. This method has the advantage that it is easy to screen for proteins with minimal functional defects (this is difficult to achieve by conventional mutagenic techniques) and also that some of the mutations introduced would be expected to require two base changes. It also has some limitations. Mutations can be introduced only at positions where the wild type can be mutated into one of the three 'stop' signals. It is known that not all sites are equally susceptible to mutagenesis and the distribution of these 'hot spots' has been the subject of a previous paper (Farabaugh *et al. J. molec. Biol.* **126**, 847; 1978). The amino acids that may be introduced are limited by the availability of suppressor strains, although there seems to be no reason why the number of these could not be increased in the future. Miller *et al.* have collected more than 300 mutants at 90 out of the 360 positions in the *lac* repressor and these can be altered in various ways: inducer binding, ability to form tetramers and binding to DNA (either operator or

0028-0836/79/290195-02$01.00

©Macmillan Journals Ltd 1979

nonspecific) can all be altered. It has been known for some time that it is the amino end of the protein that is involved in DNA binding (for example, *Nature*, **268**, 196; 1977) and it is therefore not surprising that mutations in this region frequently abolish DNA binding (*J. molec. Biol.* **130**, 191; 1979), whereas mutations at the carboxyl end are often without effect. Indeed a chimaera between the *lac* repressor and β-galactosidase produced by a deletion mutant of *E.coli* (Brake *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4824; 1978) which is without the last four residues at the C terminus but has instead nearly 10^5 daltons of β-galactosidase, retains all the various properties of the repressor. It is therefore interesting that when the Tyr 273 is replaced with Gln, the tight operator binding of the repressor disappears. Tyrosine residues have already been implicated in specific protein–nucleic acid recognition both as a result of model studies (Wehling *et al. Nucleic Acid. Res.* **4**, 513; 1977; Brun *et al. Biochemistry* **14**, 558; 1975) and also from work on gene 5 protein from bacteriophage fd (Coleman & Armitage *Biochemistry*, **17**, 5038; 1978) on gene 32 protein from bacteriophage T4 (Anderson & Coleman *Biochemistry*, **14**, 5485; 1976), as well as in the N-terminal region of the *lac* repressor (Alexander *et al. Biochim. biophys. Acta* **493**, 367; 1977).

Miller and Schmeissner have also analysed many missense mutations in which the use of chemical mutagens has resulted simply in the substitution of one amino acid for another (*J. molec. Biol.* **130**, 223, 1979). As expected, the concentration of i^-mutants (where there is no active repressor, so that the *lac* enzymes are constitutive) is particularly high among the first 60 amino acids. The i^s mutants are those in which the *lac* enzymes are repressed even in the presence of inducer and none of these occurs in the early part of the gene. This is exactly as expected because it is known that the binding site for IPTG (a synthetic inducer) depends on residues 60-360 and not on 1-59 (for example, *Nature* **268**, 196; 1977).

When the results of the suppressed nonsense mutations are taken together with those for the missense mutations (*J. molec. Biol.* **130**, 249; 1979) some striking regularities appear. For example, the positions where i_s mutants occur in clusters about 26 amino acids apart (that is, around 193, 219, 245, 271 and apart (that is, around 193, 219, 245, 271 and 297) both for missense mutations and for suppressed nonsense mutations. The exact significance of this is not yet clear, but Miller speculates that the inducer binding site may resemble the antigen-binding site of immunoglobulins. This is a cavity formed by residues in hairpin turns. The hypervariable regions occur at the turns themselves and mutations here affect the antigen-binding properties without causing alteration of the overall structure of the protein. If a similar regular structure were used to make the inducer binding site then mutations at the turns (assuming them to be about 26 amino acids apart) might alter inducer binding while leaving the overall protein structure unaltered.

All this must remain speculative until physical studies define the three-dimensional structures of the repressor and its complexes with inducer and operator. Nuclear magnetic resonance (NMR) is giving increasingly detailed information about such structures. Lu and his colleagues have grown *E.coli* on 3-fluorotyrosine in place of tyrosine and have isolated a fluorinated *lac* repressor (*Proc. natn. Acad. Sci. U.S.A.* **73**, 3471; 1976) and have now succeeded in assigning most of the ^{19}F peaks in an NMR spectrum to individual tyrosine residues (P. Lu, personal communication). Comparison of the proton NMR spectrum of the intact protein with the amino tails (residues 1–51) and the remaining core, shows that the tails have the same structure whether on their own or as part of the complete repressor (Buck *et al. FEBS Lett.* **96**, 335; 1978). Further, the narrowness of the linewidths suggests that the tails have a faster tumbling rate than would be expected if they were an integral part of a protein. It seems as if there must be a very flexible 'hinge' between positions 50 and 60 which allows the core and the tails almost independent motion.

The other half of the problem of course is to study the operator DNA. Caruthers and colleagues (Goeddel *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 3578; 1978) have synthesised *lac* operators substituted with nucleotide analogues such as 5-bromouracil, 5-bromocytidine, uracil and hypoxanthine. These and previous binding studies (Ogata & Gilbert *Proc. natn. Acad. Sci. U.S.A.* **74**, 4973; 1977) suggest that the repressor binds in the major groove on one side of the DNA only. Narang has used his phosphotriester method to synthesise various sections of the operator (Narang *et al. Can. J. Biochem.* **55**, 1125; 1977) and has now studied amino acid binding to the central nine base pair sequence. (Patel *et al. Biochem. biophys. Res. Commun.* **85**, 1560, 1978) The free energies of binding tyrosine and glutamine to this oligonucleotide are both about 17 kJ mol^{-1}. Because the free energy for binding intact repressor to intact operator is only about 73 kJ mol^{-1}, it seems possible that only four or five amino acid–base interactions may be required to produce this free energy; it is already known from the mutation studies that nine amino acids in the tail section are essential (including Tyr 17, Gln 18 and Gln 54).

It looks as though the lac repressor is beginning to yield to the combined skills of geneticists, chemists and biophysicists. □

DNA gyrase and DNA unwinding

from David T. Denhardt

WHEN DNA is replicated, transcribed, recombined or otherwise manipulated within the cell the two strands of the double helix have to be at least partially unwound. The physical problems inherent in unwinding the DNA duplex have long been recognised and led John Cairns some years ago to postulate a 'swivel' in the circular chromosome of *Escherichia coli* to enable it to be unwound. The 'swivel' has now been recast as the bacterial topoisomerases — topoisomerase I, or ω protein, and topoisomerase II, or DNA gyrase — and the latter has been implicated as an essential enzyme in DNA replication in bacteria. DNA gyrase introduces negative superhelical twists into relaxed closed circular DNA molecules; how it does this, and how this property is related to its role in DNA replication are now under intensive study. The best guess at the moment is that it relieves the positive supertwisting that builds up in front of the replication fork as the two strands are unwound during replication. Negatively superhelical DNA may also be essential for both the initiation of replication and some recombinational events.

The relation between the helical turns in a DNA duplex and the superhelical twists in a superhelical molecule are illustrated diagramatically in Fig. 1. A closed circular duplex is equivalent topologically to a linear molecule whose ends are unable to rotate, and despite appearances all three structures in the figure have the same net number (5) of twists of one strand about the other. The two negative superhelical twists in the molecule on the right are removed by unwinding two turns in the DNA duplex; if the duplex is unwound further positive superhelical twists are introduced. To understand the action of gyrase imagine the molecule in the centre to be a DNA molecule with its usual one duplex turn per roughly 10 base pairs. Gyrase binds to the DNA molecule in such a way as to introduce compensating positive and negative superhelical twists and then it breaks and reseals the DNA duplex so as to selectively remove the positive superhelical twist. Dissociation of gyrase from the DNA leaves a negatively superhelical molecule.

Evidence for the existence of DNA gyrase was first obtained by Kiyoshi Mizuuchi and Howard Nash who found that closed circular phage lambda DNA was much more efficient at undergoing an intramolecular recombination event than was nicked circular DNA (*Proc. natn. Acad. Sci. U.S.A.* **73**, 3524; 1976); a nick (a

Fig. 1

single-strand break) in a DNA molecule prevents it from being made superhelical. Martin Gellert, together with Mizuuchi, O'Dea and Nash at the US National Institutes of Health, subsequently succeeded in purifying an ATP-dependent activity that converted relaxed closed circular DNA into negatively superhelical DNA (*Proc. natn. Acad. Sci. U.S.A.* **73**, 3872; 1976). They showed that the antibiotics novobiocin and its more active analogue coumermycin A_1 inhibited DNA supertwisting and DNA replication in *E. coli* by their ability to inhibit DNA gyrase; mutations in the *cou* gene simultaneously conferred resistance to both these drugs and produced a gyrase that was drug-resistant *in vitro* (*Proc. natn. Acad. Sci. U.S.A.* **73**, 4474; 1976).

At the same time Nicholas Cozzarelli and colleagues at the University of Chicago were approaching the discovery of gyrase from a different direction. They had purified the protein product — Pnal — which confers sensitivity to the antibiotic nalidixic acid on *E. coli*. Because nalidixic acid inhibited DNA gyrase *in vitro* Gellert suggested to Cozzarelli that Pnal might be related to DNA gyrase, and this was soon proved to be so.

Functional gyrase is a 400,000 molecular weight tetramer composed of two pairs of identical subunits of molecular weights of about 105,000 and 95,000 (Higgins *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 5960; 1978). These polypeptides are coded for by the *nalA* and *cou* genes respectively; it has been proposed that the genes now be called *gyrA* and *gyrB*. Either subunit alone is inactive but they readily associate to form the native enzyme. Leroy Liu and James Wang, at Harvard University, purified the analogous enzyme from *Micrococcus luteus* and the two enzymes seem to have similar properties (*Proc. natn. Acad. Sci. U.S.A.* **75**, 2098; 1978).

What does gyrase do? Dissection of its activity has revealed several aspects of gyrase action. First, it can bind to DNA. Second, it can hydrolyse ATP in a DNA duplex-dependent reaction; this is the activity inhibited by coumermycin (Sugino & Cozzarelli, *J. biol. Chem.* in the press). Third, in the absence of ATP it removes superhelical turns from DNA by the breakage and reunion of the two DNA strands. This is inhibited by nalidixic acid. It is not yet clear whether *in vivo*, gyrase would induce a single-stranded break only, allowing rotation of one strand around the other, or whether double-stranded breaks are transiently induced. Double-strand breaks are observed when dodecyl sulphate is added to a nalidixic acid-inhibited reaction. This has allowed preferred sites for gyrase action to be identified. The break in one of the DNA strands is separated by four base pairs from the break in the other producing a linear molecule with protruding 5′ ends to which the protein seems to be covalently bound. The 3′ ends in contrast are free and able to prime a limited amount of synthesis by DNA polymerase. This provides the handle needed to determine the sequence around the cleavage site. As shown in a paper in the May issue of *Cell* there seems to be little similarity in the nucleotide sequences around the sites of cleavage in the different molecules studied so far except that on at least one strand, cleavage usually occurs between a T and G (Morrison & Cozzarelli *Cell* **17**, 175; 1979).

The binding of gyrase to DNA has been studied in detail and strong evidence suggests that the DNA is wrapped around the outside of the enzyme. Liu and Wang bound nicked circular duplex DNA to gyrase in the absence of ATP and then closed the nick with polynucleotide ligase. When gyrase was removed they found that the DNA had acquired positive superhelical twists. This implied that either the DNA wraps around the protein or that when gyrase binds to DNA it induces a winding of the helix. As there is no precedent for the latter but the precedent of DNA wrapping around histones in eukaryotic DNA for the former this explanation seemed more likely. They have since shown that when DNA is in a complex with gyrase a 143 base-pair segment is protected from digestion by *Staphylococcus* nuclease. When the gyrase–DNA complex was digested instead with DNase I, electrophoresis of the protected DNA after denaturation revealed a set of six single-stranded molecules of lengths, 47,57,67,77,86 and 96 nucleotides. It seems likely that the DNA is lying largely on the surface of the enzyme in a form inaccessible to staphylococcal nuclease but partially accessible to DNase I such that the latter enzyme can nick the duplex over a limited region at one of several sites separated by 10-base pair intervals (Liu & Wang, *Cell* **15**, 979, 1978).

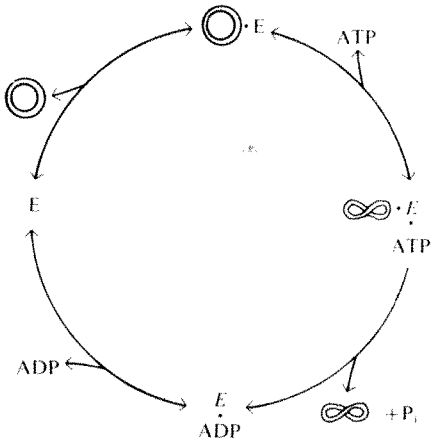

Fig. 2

Using a similar approach Peebles *et al.* (*Cold Spring Harbor Symp. quant. Biol*, **43**, in the press) also confirmed that gyrase introduced positive superhelical twists into relaxed closed circular DNA in the absence of ATP. They then went one step further. To the gyrase–DNA complex they added an ATP analogue which although it induces a conformational change in the gyrase molecule cannot support the cleavage reaction. Subsequent treatment with nalidixic acid and dodecyl sulphate to induce double-strand breaks showed that reaction with the ATP analogue had shifted the cleavage site some distance along the DNA molecule. Also, about half the positive superhelical twists introduced into the DNA on gyrase binding had disappeared.

There is now sufficient information to construct a model for gyrase action. All its elements are common to one or more of the models suggested by the several groups studying the enzyme. As proposed by Wang, on binding the DNA wraps around the enzyme. As proposed by Cozzarelli (Sugino *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4838; 1978) ATP then interacts with the enzyme to induce a conformational change that results in the translocation of the DNA relative to the enzyme and formation of a positive superhelical loop of DNA. As proposed by Gellert *et al.*, (*Cold Spring Harbor Symp. quant. Biol.* **43**, in the press) a nicking–closing cycle (or breakage and reunion if a double-strand break is transiently introduced) removes the positive superhelical turn in the isolated section of DNA. ATP hydrolysis returns the enzyme to its initial conformation and leaves the DNA with a net negative superhelical twist. The end result is that the DNA has been partly unwound. The similarity of this mechanism to other ATP-coupled energy-transducing processes has been discussed by Sugino *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 4838; 1978) and Peebles *et al.* (*Cold Spring Harbor Symp. quant. Biol.* **43**, in the press) and their model is illustrated in Fig. 2. E and *E* are two conformations of the enzyme.

In vivo evidence of the role of gyrase in the bacterial cell is provided by the inhibition of DNA replication by the antibiotics nalidixic acid and coumermycin and their analogues. Conditional lethal mutations have also been mapped in the *nalA* gene and possibly the *cou* gene (Kreuzer *et al. Molec. gen. genet.* **167**, 129; 1978; Projan & Wechsler in *DNA Synthesis: Present and Future*, 387, (ed Molineux & Kohiyama, Plenum, 1978).

The requirement for gyrase may simply be to remove positive superhelical twists

0028-0836/79/290197-02$01.00

©Macmillan Journals Ltd 1979

induced in the DNA by the unwinding of the DNA during replication. Alternatively, or additionally, the DNA may need to be made negatively superhelical for DNA replication to be initiated. Negatively superhelical DNA is required for the initiation of replication of the bacteriophage ϕX174 replicative form DNA *in vitro* because the ϕX174 gene A protein, which must nick the DNA to intiate replication, does not act on relaxed DNA (Marians *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 1965; 1977).

Surprisingly gyrase seems to be required for the replication of the linear DNA of the phage T7 *in vivo* but not *in vitro* (DeWyngaert & Hinkle *J. Virol.* **29**, 529; 1979). The most likely explanation is that in the cell the DNA is collapsed into a compact structure as a result of its interaction with cellular molecules, whereas in its isolated form *in vitro* one end of the duplex is free to rotate relative to the other end and so superhelical twists cannot build up in the molecule.

McCarthy (*J. molec. biol.* **127**, 265; 1979) has discovered that the T4 DNA-delay mutants (*39,52,60*) require DNA gyrase for replication as they are unable to replicate in the presence of novobiocin or coumermycin in sensitive, but not drug-resistant, cells. Wild type T4 was not dependent on gyrase function, presumably because the products of one or more of the above genes form an enzyme that provides an equivalent function. From the kinetics of DNA synthesis under conditions of gyrase inhibition McCarthy deduced that the activity was required for the initiation of 'growing points' but not for the actual DNA elongation process.

On the assumption that transcription and recombination require local unwinding of the DNA it is hardly surprising that in certain cases gyrase seems to be required for both. However, the weight of the evidence suggests that gyrase is only required for transcription from some promoters (Smith *et al. Nature* **275**, 420; 1978). It is not obvious why. Harking back to the *in vitro* studies on integrative recombination in phage lambda from which the existence of gyrase was inferred it seems likely that the requirement for gyrase in recombination may be a consequence of the need for negatively superhelical DNA for this reaction, as well as for its role in DNA unwinding (Mizuuchi *et al. J. molec. Biol.* **121**, 375; 1978). One explanation for the requirement for negatively superhelical DNA is that the negative superhelical turns facilitate the uptake of pieces of single-stranded DNA to form partially triple-stranded structures. (Beattie *et al. J. molec Biol.* **116**, 783; 1977).

It is relevant to note that those DNA metabolic processes that are coupled to gyrase action become directly dependent on the ATP content of the cell, and a high ATP content at that, since the K_m of gyrase for ATP is of the order of 300 μm. If the cell cannot generate adequate supplies of energy the negative supertwisting of the DNA will rapidly disappear. With its disappearance those reactions which depend on having a negatively superhelical DNA substrate will not take place. The advantage of this as a control point in the prokaryotic cell is self-evident. Negative supertwisting, or its absence, is a signal transmitted throughout the entire DNA molecule, or at least that section of it that behaves as a topological unit.

So far gyrase has not been found in eukaryotic cells and there is no reason to expect it. The eukaryotic nicking–closing enzyme is sufficient to remove the positive superhelical twists induced in the DNA during replication. the superhelical twists present, for example, in purified SV40 DNA are accounted for by the number of nucleosomes in the DNA. (Each turn of the DNA around a nucleosome is approximately equivalent to one superhelical twist). Consequently eukaryotic DNA is not under an unwinding stress resulting from the presence of negative superhelical twists and this could be a partial explanation for its being replicated more slowly than prokaryotic DNA. □

Oceanic heat flow, lithosphere age and thickness

from Geoff Brown

THE systematic decrease of measured heat flow with increasing age of oceanic lithosphere was well documented by the classic work of Sclater and Francheteau (*Geophys. Jl. R. astr. Soc.* **20**, 509; 1970). But in more recent years a definitive relation has been sought as proof that plate thickness increases as the square root of time. This relation follows naturally from the theory of conductive heat losses which lead to the cooling, contraction and basal freezing of oceanic lithosphere as it moves away from the zone of spreading.

A thermal model relating plate thickness, age (<120 Ma) and heat flow was summarised by Parsons and Sclater (*J. geophys. Res.* **82**, 803; 1977) who cited evidence from the North Pacific that q varies as $t^{-½}$ (q = heat flow, t = age). However, their data were limited to crust of age <20 Ma and >70 Ma because the reliability of heat flow and/or age control was inadequate for other times and places. In the main, uncertainties arose from the highly scattered heat flow values caused by hydrothermal disturbance in layer 1. Sclater and Crowe (*J. geophys. Res.* **84**, 1593; 1979) have taken an important step forward by measuring heat flow at 17 stations close to magnetic anomaly 13 (age = 35 Ma) on the Reykjanes ridge. By using piston cores and measuring thermal gradients across intervals down to 12 m in sediment they were able to isolate non-linear gradients above 5 m (sediments affected by recent changes in ocean bottom water temperature) from 'remarkably linear' gradients below 7.5 m. In the former case, anomalously high, non-equilibrium temperature gradients were attributed to recent changes in seawater temperature due to changes in the velocity and temperature of Norwegian Sea overflow water. The stable gradients below 7.5 m ranged from 69.9 to 102.2 mW m^{-2}, giving a mean heat flow for anomaly 13 of 82.9 ± 10.1 mW m^{-2}. The variations in these data are real in that they exceed the precision of measurement and an excellent inverse correlation, local to the survey area, was found between heat flow and depth of sediment overlying a seismic basement ridge. This suggested that either heat flow is refracted because of the contrasting thermal conductivity between layer 1 and layer 2 (that is, due to the insulating effect of the sediments) or that the interface between the layers is isothermal due to hydrothermal convection in the deeper layer: both explanations can account for the observed local variations in heat flow.

Sclater and Crowe have shown that reliable conductive heat flow data for oceanic lithosphere can be obtained by detailed and critical analysis of down-core temperature variations. Moreover, their results from the Reykjanes ridge fall on the $q/t^{-½}$ graph for Pacific data of other ages and provide further support for the thermal model of lithospheric thickening in proportion to the square root of age.

Glow-worms

Shelley sings of a "glow-worm golden in a dell of dew," but last night, at 10 o'clock, while travelling on a bridle path among the bleak lonely mountains of Tynron, Dumfriesshire, bearing up against a high wind with cold rain, I espied three glow-worms shining among the grass and ferns. I had seen them in the same locality before, but scarcely expected to have noticed them in such ungenial weather when summer has with us scarcely yet begun. J. S.

The Loch Lomond Stadial in the British Isles

J. B. Sissons

Department of Geography, University of Edinburgh, High School Yards, Edinburgh, UK

During the last very cold period in the British Isles, which occurred more than 10,000 radiocarbon years ago, glaciers developed in many mountain areas, permafrost was extensive, frost break-up of rocks was severe (its effects including a pronounced coastal platform and cliff), downslope movement of debris was greatly accelerated, many rivers spread coarse debris over low ground, the vegetation was transformed and the fauna was greatly affected.

FOLLOWING the decay of the last ice sheet[1], oceanic polar water spread southwards again and reached the latitude of south-west Ireland[2]. The associated cold period in the British Isles is the Loch Lomond Stadial, approximately equivalent to the Younger Dryas of Scandinavia. The effects of the stadial were probably more pronounced and varied in the British Isles than anywhere else, due partly to varied relief but particularly to maritime location and the position of the maximal extent of polar water. Norway is similarly susceptible to oceanic temperature changes but was then mostly covered by the Scandinavian ice sheet. In continental countries now bordering the southern North Sea, the maritime influence would have been diminished due to location and because this part of the North Sea was then land (because of low world sea level). Comparison of pollen-bearing Younger Dryas sediments from many sites shows that very distinctive floras and sediments occur in the British Isles, but the stadial changes are less marked in the North European Plain and diminish southwards and eastwards of it[3].

Glaciers

Small cirque glaciers developed at various places in the mountains of Ireland and Wales. Their maximal limits are normally defined by fresh-looking end moraines; other end moraines frequently record subsequent intermittent retreat. In Ireland such moraines occur, for example, in the Wicklow, Mourne and Galty mountains, in the Nephin Beg range, in County Donegal and in western County Kerry[4]. In Wales they are present, for example, in the Brecknock Beacons, on Cader Idris and especially in Snowdonia[5–8].

The 64 glaciers that developed in the Lake District included many small cirque glaciers but there were also valley glaciers up to 5 km long (Fig. 1). The limits of the majority of the glaciers are marked by end moraines, the limiting moraine being often immediately succeeded by one to three other moraines. In a few places fluted moraines record the final direction of the ice movement and in many places hummocky moraine lies within the limits of the former glaciers. Despite their considerable number, the Lake District glaciers covered an area of only 55 km^2 and their combined volume was only 3.3 km^3. Small glaciers are said to have existed in the northern Pennines[9] and an isolated one developed on the Cheviot. In the Southern Uplands of Scotland, glaciers were most extensive in the centre around Broad Law but even here the largest was only a few kilometres long.

In total contrast a very large area of glacier ice accumulated in the western highlands of Scotland: its ice-shed altitude attained 850–900 m, numerous mountains (not shown in Fig. 2) rising above its surface. Over Rannoch Moor its thickness exceeded 400 m and in the southern Great Glen reached 600 m. One small part of this ice mass, the Loch Lomond Glacier, had a volume of ~80 km^3, thus far exceeding the combined volume of all the glaciers mentioned above[10]. The numerous other glaciers that formed in the Scottish Highlands and some of the islands included many small cirque glaciers as well as valley glaciers up to 10 km long. Some glaciers developed beneath rock walls lacking cirque form and others in broad, shallow valleys in plateau surfaces. This last type of accumulation resulted in an ice cap of 65 km^2 in the south-east Grampians and one of 360 km^2 in the central Grampians[11–20]. Yet glaciers were not ubiquitous in the Highlands. In the Monadhliath Mountains, where a large area of ground exceeds 600 m, there were only two; in the north-west Cairngorms only three out of seven cirques at 1,000 m altitude contained glaciers[19].

The landforms produced by the stadial glaciers in the Highlands are often clear and abundant. There are scores of end moraines, many of them small, but the longest extend continuously for 15 km or intermittently for 40 km, the highest has outer slopes 30–40 m high, and the broadest individual end moraine ridges are 200 m wide. These clear, often arcuate, end moraines record the maximal extent of many of the former glaciers: other clear end moraines often occur immediately behind them.

Many glaciers left extensive areas of hummocky moraine in the Scottish Highlands and some small ones deposited great quantities of boulders as continuous undulating spreads. Fluted moraines are especially common in north-west Scotland and Mull[12,16]. Hundreds of small (1–4 m deep) meltwater channels were formed in association with the large plateau ice cap of the central Grampians[14]. Outwash terraces occur at and near the limits of many of the former glaciers in the central and eastern Grampians but are small compared with a buried outwash fan in the western Forth valley[21] and with outwash masses at certain west coast localities (for example, by Lochs Etive, Linnhe and Shiel)[22,23]. Yet the morphological evidence is not prolific everywhere: the limit of the large west Highland ice mass is

0028–0836/79/290199—05 $01.00

© Macmillan Journals Ltd 1979

still not fully mapped partly due to the lack of clear landforms (Fig. 2).

Ice-dammed lakes

A lake held up by the Glen Moriston glacier (west of Loch Ness) occupied at least nine different levels, seven of them marked by shorelines. Excellent cross-valley moraines were formed at the ice margin during retreat. Sudden release of lake waters produced belts of rock swept free of drift that extend intermittently for several kilometres[17]. The 'parallel roads' of glens Roy, Gloy and Spean are mainly lake shorelines[24] formed by frost erosion and occur at five levels in Glen Roy[25]. The final Roy/Spean lake had an area of 73 km^2, a maximal depth of 200 m and a volume of 5 km^3. It has been suggested that catastrophic emptying of this lake in a few days, with peak discharge of 22,500 $m^3 s^{-1}$, caused the surface level of Loch Ness to rise 8.5 m and resulted in a massive spread of sand and gravel at the southern end of the loch[26].

Periglacial activity

The very cold climate of the stadial resulted in widespread and varied periglacial activity. In the Scottish Highlands especially, powerful frost wedging produced blockfields and extensive spreads of smaller debris that now mantle many summits and plateaus. Such debris often moved down slopes as sheets with steep, often crenulate (lobate) frontal margins typically 1–5 m high, the agency probably being interstitial ice. In many places formation may have begun during ice-sheet decay but the major lobes and sheets as now widely preserved in fossil form were produced during the stadial, this being in accord with their absence from ground then occupied by glaciers.

At the base of a few slopes in the north-west Cairngorms and the Lake District accumulations of coarse debris with steep fronts up to 10 m high seem to be fossilised valley-wall rock glaciers. Fossil rock glaciers with curving terminal ridges resembling end moraines occur in the north-west Cairngorms and Jura, having been supplied with abundant coarse debris from adjacent steep slopes[19,27]. Deposits associated with former perennial snow beds are much more common. Protalus ramparts occur in Snowdonia[6] and one on Fan Fawr in south Wales is 11 m high[7]. They also occur in the Lake District and at many locations in the Scottish Highlands, one in the Cairngorms having an outer slope 10–20 m high. By far the largest feature known is a complex rampart in north-west Scotland, which is 1 km long and up to 55 m high, its volume implying a 17 m retreat of the rock face that supplied it[28]. Some snow-bed deposits comprise groups of mounds of angular debris (for example, in the Lake District) and others consist of great quantities of boulders forming spreads and ill-defined heaps; one such deposit in the Cairngorms extends for 2 km. None of the above features is firmly dated although their distribution complements that of the stadial glaciers, implying approximate contemporaneity of formation.

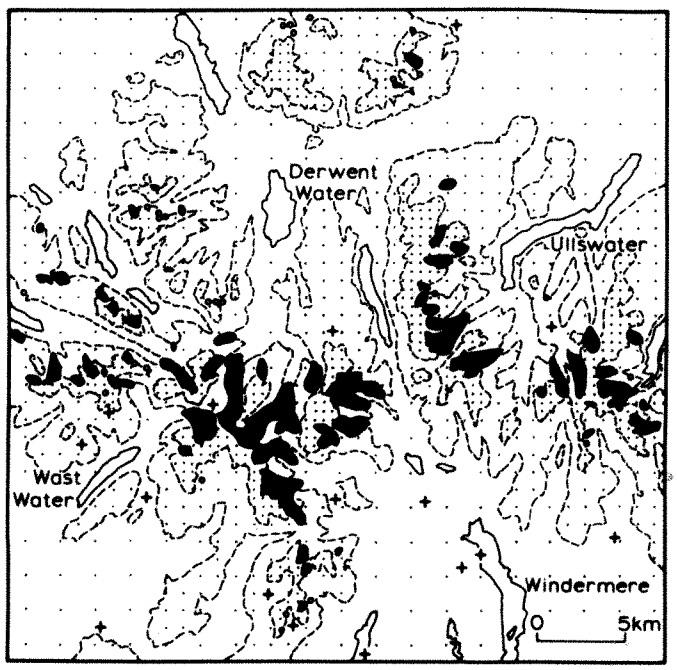

Fig. 1 Extent of stadial glaciers (solid) and locations of perennial snow beds (circles) in the Lake District. Lateglacial pollen sites shown by crosses. Altitude indicated by density of stipple, contours being at 300 and 600 m. Based on refs 103 and 110 and unpublished data.

Fossil screes are widespread: in Wales, for example, they occur especially on south- and west-facing slopes favoured by frequent freeze–thaw cycles. The near-surface layer of angular gravel, often ~0.5 m thick, is believed to have accumulated during the Loch Lomond Stadial[29,30]. Downslope movement of debris at low altitudes during the stadial is demonstrated in the Glasgow area, Dumfriesshire, Banffshire and the East Midlands by radiocarbon dates[31–34]. In Edinburgh a 2 m layer of stratified stony clay sandwiched between lake deposits[35,36] suggests stadial transfer of debris from Salisbury Crags by solifluction and snow meltwater over an average slope of 4–5°. Much further south, rapid frost break-up of the chalk occurred and trails of chalk rubble and mud extend for 2 km from coombes in the North Downs. These sheets of chalky slurry were carried by water released from melting snow and thawing of frozen ground. They often overlie an organic layer representing the Windermere Interstadial and their volume implies that at least some coombes were mainly formed during the stadial[37,38]. Soil instability and incomplete vegetation cover are indicated widely in the British Isles by minerogenic deposits in present and former lakes (although the minerogenic layer may not correspond exactly with the stadial as indicated by pollen analysis).

Occasional thin seams of silt in chalky stadial deposits point to wind action[37,38]. A radiocarbon date and pollen analyses show that part of the wind-blown Shirdley Hill Sand of Lancashire accumulated during the stadial[39]. In the Vale of York and vicinity wind-blown sand occurs extensively as slightly hummocky sheets or as low dunes, radiocarbon dates demonstrating mainly stadial deposition[40–42]. Small fossil wedges infilled with the sand suggest permafrost, as do the wedges related to the stadial scree deposits in central Wales[29,30] and frost cracks associated with a stadial gravel layer in Buckinghamshire[43]. In Wales organic sedimentation in features interpreted as fossil pingos began very early in the Flandrian[44–46], suggesting they ceased to form during the stadial, but this is not readily reconcilable with their thick infill (10 m) of clay. Pollen analysis suggests that some at least of the small (30–75 m diameter) pingos of south-east Ireland formed during the stadial[47]. Some of the fossil pingos on chalk near Cambridge are believed to have existed at this time, their restriction to locations where hydrological conditions were most suitable suggesting that permafrost was discontinuous[48]. Fossil frost wedges just within the Loch Lomond Advance limit at three western sites near sea level in Scotland point to widespread permafrost in that country[49].

Fluvial activity

Snowmelt and surface thawing of frozen ground together with direct precipitation caused spring floods and abundant deposition on low ground. In Edinburgh (Corstorphine Loch) an extensive alluvial fan is dated by Windermere Interstadial deposits below it and Flandrian deposits above it. The age of large fans at the mouths of small tributary valleys in Glen Roy is demonstrated by their relation to the former ice-dammed lake. The lower parts of numerous valleys cut in sandy raised beach deposits in Scotland are infilled with very early Flandrian marine deposits, implying their excavation during the stadial when subsurface drainage was prevented by permafrost[50]. At the mouths of three Longmynd valleys in Shropshire fans of angular

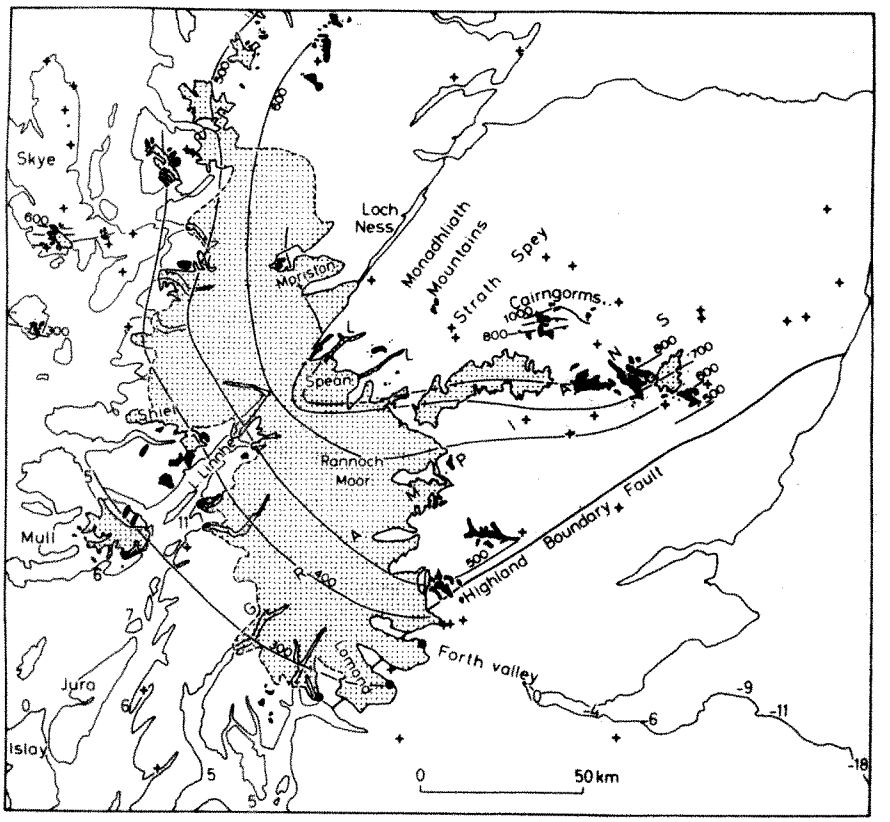

Fig. 2 Extent of stadial glaciers in part of the Scottish Highlands (stipple and solid) and regional firn-line altitudes (100 m interval): a dashed line is used where glacier limits are not yet mapped. Radiocarbon-dated marine shell sites related to glaciers shown by dots. Late-glacial pollen sites shown by crosses. Ice-dammed lakes of the Glen Roy area shaded and marked L. Representative altitudes for the Main Lateglacial Shoreline are indicated. Based on numerous sources including unpublished data provided by H. J. B. Birks, M. Robinson, D. G. Sutherland, K. S. R. Thompson, P. Thorpe and T. Wain-Hobson.

debris, one known to overlie Windermere Interstadial deposits, were partly laid down by stadial floods[51]. Even in the low-amplitude relief of Suffolk radiocarbon dates and other evidence indicate that sand and gravel deposits up to 400 m wide and 12 m thick accumulated in the Gipping valley during the stadial and very early Flandrian[52].

Flora and fauna

Open tundra vegetation prevailed during the stadial: there is only occasional macroscopic evidence suggesting the existence of tree birches, as at one site in Skye[53] and in the lower stadial deposits of a site in Lincolnshire[54], but dwarf birch was common. In pollen profiles annual pollen deposition rates are low and there is an increase in poorly preserved pollen. Pollen of Compositae, Cruciferae, Caryophyllaceae and Chenopodiaceae accord with open ground and disturbed soils, *Rumex* often being abundant and *Artemisia* especially characteristic. Large areas of fresh mineral soils are indicated by pollen of plants that favour base-rich conditions. The very low carbon content of stadial sediments in some lake sites in the Lake District and northern Scotland implies complete destruction of soils developed in the preceding interstadial, as well as low aquatic productivity[55–57]. The large numbers of moss spores in the sediments and, in northern Scotland, an increase (compared with underlying sediments) in the proportion of aerophile diatom taxa[58] are in accord with this evidence.

The crustacean *Lepidurus arcticus* has been found in stadial deposits in many parts of the British Isles. At Blelham Bog in the Lake District the arctic Cladocera *Chrydorus sphaericus* and *Acroperus harpae* increased in numbers[59]. Among beetles there was a preponderance of northern species, such as *Nebria nivalis* Pk, which is now found in Scotland only on the highest mountains, and *Bembidion dauricum*, now in Europe confined to arctic Norway and Swedish Lapland[60–64]. Vertebrates included reindeer, arctic lemming, Norway lemming, tundra vole and ptarmigan[65,66].

Marine activity

The stadial in some Scottish inshore waters is represented by thick deposits (such as 13 m) with foraminifera, ostracoda and/or dynoflagellate cysts indicating cold or very cold conditions[67,68]. These overlie interstadial 'Clyde beds', whose limited distribution above sea level is largely determined by marine erosion that occurred during the following cold period. This erosion, due to severe frost action combined with wave action, produced a platform often 20–30 m (but sometimes over 150 m) wide backed by a cliff up to 15 m high now seen on the Scottish coast between Loch Linnhe and the Firth of Clyde[69–71]. The shoreline (Main Lateglacial Shoreline) slopes owing to glacio-isostatic recovery, having a maximal altitude of ~11 m near Oban and passing below sea level in southern Kintyre and north-east Islay. Around Grangemouth in the Forth valley 28 km^2 of drift and, locally, bedrock were planated[50]. The shoreline is at −18 m, 9 km north of Berwick (Fig. 2), where the associated rock platform is probably 600 m wide[72,73]. The buried channel of the Tweed may well relate to this low sea level because it descends to ~−20 m and, significantly, lacks glacial till[74]. Pre- and post-stadial sea-level evidence from southern parts of England, Wales and Ireland[75–83] suggests a stadial sea level there between −35 and −50 m. The Main Lateglacial Shoreline may be represented by the sharp break of slope traced for 30 km at −35 to −40 m in Cardigan Bay[84] and by the pronounced erosional shoreline at −42 m identified off part of the coast of south-west England[85,86].

Climate

All the preceding evidence is intimately linked to climate. Suggested mean July temperatures for the stadial are 10 °C for southern England and 9 °C for northern England (beetle evidence)[63], 7.5 °C for the Lake District[9], 7 °C for the south-west Grampians[10] and 6 °C for the south-east Grampians[87] (sea level values based on glaciers). Since discontinuous permafrost indicates a mean annual temperature no higher than −1 °C, such figures imply a greater annual temperature range than at present, as (independently) do beetle assemblages; causes include greater differences than now between amounts of winter and summer solar radiation reaching the top of the atmosphere over the British Isles[88]: the smaller North Sea, probable freezing of the surface of this sea in winter, and an ice sheet over most of Scandinavia.

Glacier dimensions, altitudes and distributions imply that the principal snowfalls were associated with south to south-east air streams preceding warm or occluded fronts, although south-west air streams were important contributors of precipitation in western areas[10]. This suggests that many depressions followed more southerly tracks than prevail today[87], related to the junction of polar and warmer oceanic water masses at the latitude of south-west Ireland. The stormy climate resulted in extensive wind transfer of snow to glaciers and snow beds, especially by south-west winds, allowing widespread periglacial action on high ground thus largely denuded of snow. In the Scottish Highlands glacier firn-line altitudes (Fig. 2) imply that precipitation diminished inland from the west coast and northwards from the Highland Boundary Fault: in Strath Spey it may have been only 200–300 mm yr^{-1} (ref. 10). These precipitation inferences from glaciers in the Highlands accord broadly with proportions of *Artemisia* pollen in stadial pollen counts. Species of *Artemisia* favour well-drained ground and normally do not tolerate much snow. Percentages of *Artemisia* pollen increase eastwards into the Highlands from the west coast and northwards from the Highland Boundary Fault, culminating in Strath Spey, where at one site *Artemisia* constitutes 40–65% of total land pollen almost throughout the stadial[55,89–94].

Dating and climatic changes

Dates of ~10,800–10,300 yr BP have often been assigned to the stadial. Many radiocarbon dates are in accord but many others are not. Dates assigned to the beginning of the stadial are normally for the uppermost organic material underlying the stadial minerogenic layer in present or former lake sites. Dates may vary because of thickness of material sampled[95], contamination or other errors (several sequences show reversals) and because the initiation of minerogenic sedimentation would have been influenced by local factors (such as slope angles, and altitude) and geographic position. Due to the lag in vegetational response, and hence in the cessation of organic sedimentation, such radiocarbon dates will tend to be younger than the causative climatic change. Similarly, dates for the end of the stadial will tend to be too young, further factors here being soil removal during the stadial and slope instability. Coarse fluvial deposits continued to accumulate in the early Flandrian in Suffolk[52] and Shropshire[51] and are attributed to the very early Flandrian in the Isle of Man[96], while wind-blown sand continued to be deposited after the end of the stadial in the Vale of York[41]. In the Forth valley the highly micaceous minerogenic deposits of the Main Buried Beach, which ceased to accumulate at 9,600 yr BP[97], contrast with the overlying organic carse (mud-flat) deposits. Thus different processes that characterised the stadial operated over different periods of time and responded differently to climatic change.

Nine radiocarbon dates for material picked up or over-ridden by advancing stadial glaciers all lie between 11,800 and 11,300 yr BP[12,98–100]. Seven of these dates relate to five marine shell sites bordering the south-west Grampians (Fig. 2) and the other two are for a lake site in the Wicklow Mountains. They imply that glaciers reached their maximal extent later.

Coleoptera indicate that a decline in temperature began before 12,000 yr BP[34], Cladocera imply a deteriorating climate perhaps from ~11,800 BP[59], and some pollen evidence indicates irregularly declining temperatures from ~11,800 BP[57,101]. Since only a very few degrees drop in present summer temperatures would cause glaciers to form in Scotland[102], glaciers may have begun to develop here by 11,500 BP. Varied relief and precipitation and the southwards spread of polar water point to glacier initiation at different times in different places. The 400–450 varves of major Lake District lakes[103], which encompass both glacier advance and retreat (unpublished data) are far less numerous than those in Loch Ness[55], implying that glaciers existed for a much longer period in the Loch Ness catchment.

Retreat moraines show that some of the larger glaciers in the Lake District and central Southern Uplands withdrew actively (unpublished data). However, most Lake District glaciers and some Southern Uplands ones produced end moraines only at and near their furthest limits (in a zone 50–150 m wide). In the Scottish Highlands, except at ice-dammed lake sites and possibly at one other site, clear end moraines are restricted to the same situation, the end moraine zone being several hundred metres wide for some of the larger glaciers. It is tempting to suggest that all these end moraine zones are synchronous and that subsequently most glaciers decayed rapidly owing to the rapid rise in summer temperatures demonstrated by Coleoptera[104], this in turn being related to withdrawal of polar water (or to the latter having been rapidly over-ridden by warmer water). However, there is insufficient evidence to test this hypothesis.

Basal organic sediments from a site located behind a major end moraine at Callander have been dated as 10,670±85 yr BP[93]. Similar sediments from three sites on Rannoch Moor, in the heart area of the major stadial ice mass, range between 10,390±200 yr BP and 10,660±240 yr BP[105–108]. If valid these dates imply much earlier deglaciation than is normally assumed. It has been suggested that the dates may be too old due to the unique chemical and hence biological character of recently deglaciated terrain[109]. Yet this explanation does not apply to the Lake District evidence: here glaciers had withdrawn from the end-moraine belt before the end of the *Artemisia* pollen assemblage zone (ref. 103 and unpublished data) which, according to a radiocarbon date from Blelham Bog (located outside the glacier limits), ended before 10,650±170 yr BP[101]. This evidence suggests the attainment of glacier maxima ~10,800 yr BP, markedly out of phase with much other evidence. Many more radiocarbon dates are needed to resolve this apparent discrepancy.

I thank many present and former research students for comments.

General relativity, thermodynamics, and the Poincaré cycle

Frank J. Tipler

Department of Mathematics, University of California at Berkeley, Berkeley, California 94720

An arbitrarily close return to a previous initial state of the Universe, such as predicted by the Poincaré recurrence theorem, cannot occur in a closed universe governed by general relativity. The significance of this result for cosmology and thermodynamics is discussed.

THE idea that history repeats itself—that every state of the Universe has occurred before and will occur again *ad infinitum*—is a concept which originated thousands of years ago and in the form of the Poincaré cycle and the 'cyclic' universe, still plays an important part in fundamental physics. This notion of an 'eternal return' will be considered here in the context of general relativity, and it will be shown that in a closed universe, no arbitrarily close (or exact) return to a previous state of the universe is possible, provided certain very general restrictions on the matter tensor and global causal structure hold. This result is in stark contrast to the situation in classical mechanics: Poincaré showed[1,2] that for almost all initial states, any mechanical system with a finite number of degrees of freedom, finite total and kinetic energy, and constrained to move within a finite box must return arbitrarily closely and infinitely often to almost every previous state of the system. The reason for 'no return' in general relativity and 'eternal return' in classical mechanics is that in general relativity, singularities intervene to prevent recurrence. General-relativistic closed universes are thought to begin and end in singularities of infinite curvature, and these singularities force time in general relativity to be linear rather than cyclic.

Poincaré recurrence has been reported[2–5] to be a major stumbling block in the definition of entropy, a function of the state of the system which never decreases, in terms of the fundamental microscopic variables of the system. Hitherto the increase of an 'entropy' defined by such variables has been obtained (not very successfully) by such tricks as 'coarse-graining'[2,6]; an *ad hoc* addition of randomness to the system in the form of a postulate of 'molecular chaos' or 'random phases'[2,3]; or by taking the thermodynamic limit[7,8]. The thermodynamic limit, which involves letting the volume of the system and the number of particles it contains go to infinity, is particularly unphysical as the infinite volume limit places one in the realm of cosmology, yet the limit ignores the most important cosmological force, gravity. The results of this paper may make such processes unnecessary, and there may be a strong connection between the increase of gravitational field entropy, which does not seem to require the above tricks, and the increase of matter entropy. The paper concludes with a discussion of the significance of the no-return theorem for cosmology.

To prove that no two states of the Universe can be identical or even arbitrarily close, we must first define the notion of 'close'. This can be done by regarding the set of all initial data as a Sobolev space W^s. The global topology of the space-time (M, g) is $S \times R$, where S is compact, if the space-time is globally hyperbolic. We choose some positive definite metric e_{ab} on M,

0028-0836/79/290203—03 $01.00

© Macmillan Journals Ltd 1979

and define a norm on W^s by

$$\|K^1_j\|_m \equiv \left[\sum_{p=0}^{m}\int_S (|D^p K^1_j|)^2\, d\sigma\right]^{1/2}$$

$$\|h, \chi\| \equiv \|h\| + \|\chi\| \qquad (1)$$

where $d\sigma$ is the volume element induced on S by e_{ab}, D^p is the generalised pth covariant derivative with respect to some chosen background metric $\bar{g}_{ab}$, and single verticle lines denote is the norm induced by e_{ab} (see ref. 9, p 233–235 for more details). Two tensors will be 'close' if they are 'close' in the norm of equation (1).

Assumptions in the no-return theorem

The no-return theorem will require four conditions on the matter tensor. The first condition, the time-like convergence condition (ref. 9, p 95), says roughly that gravitation is always an attractive force. The other three conditions, are here called (a), (b) and (c) (for precise definition see ref. 9, p 254–255). Briefly, (a) says that the development from a given set of initial data is locally unique; (b) says that this unique development is locally stable; and (c) says that the stress–energy tensor is a polynomial in the matter fields, their first derivatives, and the space-time metric. As discussed by Hawking and Ellis (ref. 9, p 255), these are physically reasonable conditions to impose on the matter fields, though strictly speaking they are not necessary conditions. Any other conditions which imply global Cauchy stability and uniqueness (as defined in ref. 9 Ch. 7) would be sufficient to prove the theorem below.

We also need two global conditions. The first, the requirement of unique development from Cauchy surfaces (ref. 9, p 205), says that laplacian determinism holds for the space-time. The second, the generic condition (ref. 9, p 101) says that every causal geodesic experiences a tidal force at least once in its history. As this would be expected to be false only for a 'measure-zero' set of solutions to the Einstein equations, the generic condition in the theorem below is analogous to the 'measure-zero' qualifications in the Poincaré recurrence theorem. A closed universe is defined to be a space-time in which the Cauchy surfaces are compact. A space-time that contains two disjoint space-like Cauchy surfaces which are isometric in their initial data is said to be time periodic. (Because if the evolution equations are well-posed, the development of the second Cauchy surface will be identical to that of the first, leading to a third identical surface, and so on.)

No-return theorem

Theorem: If a space-time (M, g) containing compact Cauchy surfaces is uniquely developed from initial data on any of its Cauchy surfaces, and if (M, g) also satisfies both the generic and the time-like convergence conditions, then the space-time cannot be time periodic. Furthermore, if the matter fields ψ and their first derivatives ψ' also satisfy conditions (a), (b) and (c), then for any neighbourhood U of any Cauchy surface S_1, a number $\varepsilon > 0$ exists such that $\|(h, \chi, \psi, \psi') - (h_1, \chi_1, \psi_1, \psi'_1)\|_{a+5} > \varepsilon$ for the initial data on any Cauchy surface S with $U \cap S$ empty. (ε Depends on e_{ab}, $\bar{g}_{ab}$ and U. The Cauchy surfaces S and S_1 are assumed space-like.)

The proof of this theorem will be published elsewhere. Note that the compactness of the Cauchy surfaces—the requirement of a closed universe—is an essential condition. If the word 'compact' is removed, then the theorem is false; it does not apply to open universes. For example, a static stop in asymptotically flat space satisfies all the conditions of the theorem except compactness, and this spacetime can be foliated by Cauchy hypersurfaces normal to the timelike killing vector field. The initial data is the same on each of these hypersurfaces.

Significance of no-return theorem

One might think that any field theory in euclidean space would have a non-recurrent property similar to the one demonstrated above, as a continuous field has an infinite number of degrees of freedom. From a physical point of view, this is not the case. It is not possible to make a precise measurement of the field variables at every point, and, in practice, a field restricted to a finite region S would be approximated by dividing up S into a finite number of subregions, and the field in each subregion replaced by its average value in that subregion. Evolution would be via the differential field equations, but one would compare the 'average' values.

Comparing initial data sets via the Sobolev norm is analogous to comparing the average values of the field variables (and their derivatives) at one time with the average values at another time. With the Sobolev norm, one essentially takes the absolute square average value of the initial data over the entire Cauchy surface rather than dividing up the Cauchy surface into subregions; the Sobolev average is a coarser average. The arbitrary metrics e_{ab} and $\bar{g}_{ab}$ in the Sobolev norm are analogous to an arbitrary coordinate system with respect to which averages are calculated. In the classical mechanics of fields in a finite box, one can define a similar norm $\|\,\| = [\int |\psi|^2\, d\sigma]^{1/2}$ on the classical field ψ. The sum $\sum_{i=1}^{n} \|\psi^{(i)}\|$ with $\psi^{(i)}$ being the ith derivative of ψ, is essentially the same as the Sobolev norm. This sum is a map f from the space of all values of the field and its first n derivatives into R. If the range of f is bounded—as it must be if the solutions ψ are stable—then the evolution of ψ must result in accumulation points in the range of f. An analogous accumulation is impossible in general relativity, as the above theorem shows. In general relativity the range of f is not bounded—singularities develop in space-time (this follows from the hypotheses of the above theorem and theorem 2 of ref. 9, p 266). This sort of singular behaviour is typical of many non-linear field theories[10,11], but in linear field theories such as electromagnetism the solutions are stable and are hence bounded. For example, the solutions to the Schrödinger equation in a finite box must recur[12,13] in the above average sense: for any initial value $\psi(t_0)$ for the probability distribution and any ε, there exists a time t for which $\|\psi(t) - \psi(t_0)\| < \varepsilon$.

In a finite universe without singularities there should be a finite number of physically distinguishable states (this should also be true if the matter in the universe is in the form of fields, for reasons stated above). I would expect that the states of such a universe would evolve in general in a quasi-ergodic way[14,15]. If the evolution of the physically distinguishable states is indeed quasi-ergodic, then in infinite time, every state would with high probability occur an infinite number of times.

Another way to model the evolution of such a finite-state always-existing universe, is by regarding the evolution as a finite discrete Markov chain[16] with stationary transition probabilities. That is, we will sample the state of the Universe at definite time intervals Δt, and we will assume that the state of the Universe at time t_j is determined by the previous state at time t_{j-1} and the probability matrix of going from this previous state to any other state. If the Universe has existed for an infinite time, then with probability one the states of the Universe form a closed set (ref. 16, p 384); that is, we may consider without loss of generality that the Markov chain representing the Universe is now irreducible. By theorem 4 of ref. 16 (p 392), it follows that with probability one, all states recur in the future.

Similar arguments will imply some form of recurrence in closed universes which avoid singularities by 'bouncing' at some small radius (such behaviour could, of course, occur only if some of the conditions in the no-return theorem are violated[17]). One could envisage the physical constants of the Universe, such as the elementary particle masses, the coupling constants, the specific entropy per baryon, and so forth, changing in some fashion at each bounce. These physical constants can be regarded as additional variables in the initial data. If the number of such constants is finite and if their range of variation is finite, then in a finite universe one would expect a finite number of physically distinguishable states. This implies accumulation points in the state space with an infinite number of bounces; with quasi-ergodic or markovian evolution, we would have recurrence of all states with high probability. Quantum-mechanical

considerations do not substantially alter this conclusion, as long as the number of physically distinguishable states is to be finite.

It is, of course, possible to avoid the recurrence conclusion by assuming that the range of variation of the physical constants is not bounded, or that the Universe, although closed, increases its radius at maximum expansion with each bounce. (Tolman[18], for example, argued that the monotone increase of entropy required a monotone increase of maximum radius at each bounce.) However, if the range of physical constant variation is not bounded, then a sequence of cycles would exist such that at least one physical constant would diverge in the limit. I would regard such a divergence as a singularity 'at infinity'. If the maximum radius increases monotonically with time, then with an infinite number of bounces in the past, the sequences of values of the maximum radius must have a limit point in the past. If its limiting value is non-zero, then one must have recurrence in the past, though this 'recurrence' may take the form of a gradual cessation of change, as in the Eddington–Lemaître universe[19]. If its limiting value is zero, then the singularity has not been really removed, it has just been placed at temporal infinity.

But the singularities in the single-cycle closed universe can also be regarded as at temporal infinity. In fact, both Milne[20] and Misner[21] have contended that because physical changes occur with diverging rapidity (as measured in proper time) near a singularity, the singularity should be regarded as occurring at temporal infinity as measured in physical time. Barrow and myself[22] have pointed out that extrinsic time[23], which is a naturally defined absolute time in closed universes[24], has just this property of placing the singularities at temporal infinity. In the extrinsic time scale, a closed universe has existed and will exist forever; the question of what preceded the big bang does not arise.

Because of Poincaré recurrence, it is impossible to define a monotonically-increasing entropy (or any monotonically-increasing function) for non-gravitational fields or systems of particles in terms of the phase space variables of the fields or particles. However, since Poincaré recurrence does not hold for gravitational fields, it is possible to define functions which increase monotonically with time—such functions are called Lyapunov functions[7,8]—on the phase space of the gravitational field. In fact, the extrinsic time, which is proportional to the trace of the extrinsic curvature of a leaf of a constant mean curvature Cauchy hypersurface foliation of space-time, is just such a function, as the extrinsic curvature is essentially the momentum of the gravitational field[25] and the extrinsic time increases monotonically in closed universes, ranging from $-\infty$ at the initial singularity to $+\infty$ at the final singularity[24]. In non-singular asymptotically flat space, a foliation of constant mean curvature Cauchy surfaces would have to have extrinsic time constant ($=0$). This supports the conclusion of classical mechanics that isolated systems cannot define a time direction.

Bohr[26] together with Prigogine and his coworkers[4,8] have suggested on the basis of Poincaré recurrence that thermodynamic concepts such as temperature and entropy are complementary to the phase space variables. In other words, they argue that a detailed microscopic description of the behaviour of a physical system would preclude the definition of thermodynamic variables for that system. If the gravitational field (or more precisely, the global structure of space-time) is taken into account, we see that it becomes possible in principle to define the thermodynamic variables and the phase space variables in a closed universe simultaneously; the notion of complementarity becomes unnecessary. This leads to speculation about the connection between quantum mechanics and the global structure of space-time: perhaps the impossibility of giving a detailed deterministic microscopic description of a quantum mechanical system is due to neglect of the global structure of space-time.

Geochemical problems of the Antarctic dry areas

A. T. Wilson*

Chemistry Department and Antarctic Research Unit, University of Waikato, Hamilton, New Zealand

The dry areas of the Antarctic are extreme deserts. Because of the cold they are not subjected to rainfall and geochemical separations can take place which would be destroyed by flowing water in the more temperate deserts. The distribution of soluble salts which accumulate on the surface and in the lakes is unusual and is explained on the basis of relative humidity separation mechanism. It is suggested that similar phenomena may take place on Mars.

ALTHOUGH much of the Antarctic continent is covered with ice and snow, there are some areas which are ice free. These so-called 'dry areas' are extreme deserts, characterised by extreme cold and aridity. They are also unique among deserts in being completely rainless. All precipitation falls as snow which is largely lost by sublimation. The salt geochemistry of water soluble salts which accumulate on the surface and concentrate in the lakes and ponds of these dry areas is described here. A relative humidity separation mechanism is proposed that can only operate in rainless deserts.

Although the salt and lake geochemistry of the McMurdo dry area has been studied for almost 20 years, the geochemistry of this region is far from being understood and there is a lot of

© Macmillan Journals Ltd 1979

apparently conflicting evidence. Even the origin of the salts in the lakes is in dispute. Since chloride is a minor constituent of Antarctic rocks and very little chemical weathering takes place, one might expect the chloride in the lakes (which are mostly chlorides of Ca, Mg and Na) to have originated from the sea. However, some lakes such as Lake Vanda, are essentially calcium chloride brines, a fact that is difficult to explain by normal geochemical models. Further, Jones and Faure[1] have presented isotopic evidence to suggest that most of the strontium in Lake Vanda does not have an oceanic origin. Other problems are that adjacent lakes frequently have very different chemical compositions which often do not seem to match that of their inflow streams. Furthermore, different layers of the same lake sometimes have different ratios of their ionic constituents. The bottoms of some chemically stratified lakes, which on other evidence must have been out of contact with the atmosphere for hundreds if not thousands of years, contain measurable amounts of tritium (half life = 12.3 yr) in their bottom waters. Glaciers which would be expected to have the same composition as the regional snowfall, because polar glaciers do very little cutting, frequently produce meltwater streams with very different chemical compositions to the snow which falls on their névés.

This article describes phenomena which can occur only in polar deserts and presents evidence in support of an hypothesis which could explain all the apparently anomalous data. First, it is necessary to describe the Antarctic dry areas in detail.

Geochemistry of the Antarctic dry areas

Why are the dry areas not ice-covered like the rest of the Antarctic continent? In this cold and arid region (mean annual temperatures of the McMurdo oasis region are approximately −20 °C) only a very small fraction of the snow that falls ever melts and almost all of it is lost directly by sublimation. The dry areas are snow free because ablation processes in total exceed all the accumulation processes. There must also be favourable topography to prevent ice from regions where accumulation processes exceed abalation from flowing into and inundating the dry area. The imaginary line which divides the region of net positive accumulation from the region where ablation exceeds accumulation is called the 'snow line'[2]. For a given region the net precipitation increases as altitude is increased. As one moves from the sea inland the snow line rises; presumably because total precipitation decreases. As one descends below the snow line the environment becomes more and more arid. Parts of the McMurdo dry valleys are so dry that $CaCl_2.6H_2O$ crystallises from ice-free saline ponds (such as the Don Juan Pond[3,4]). The fact that such a deliquescent salt can exist demonstrates that this area is among the most arid on the Earth.

If one digs into the loose 'soil' of a dry area in this cold and arid region, one passes through loose dry debris and can suddenly strike a very hard and impenetrable layer, which on examination proves to be debris as above but cemented with ice crystals. This phenomenon is equivalent to the water table of the more temperate regions of the world and is called here 'the frozen water table'. The depth to this frozen water table seems to be related to distance below snow line and is probably a balance between distallation of water downwards during brief periods of snow cover and evaporation outwards during periods of low relative humidity at the surface. Certainly as one goes to higher altitudes and hence nearer to the snow line, the depth to the frozen water table decreases. During the summer, cold saline water can be found moving downslope along the surface of the frozen water table.

Drainage basins

The dry areas of Antarctica frequently consist of a number of enclosed drainage basins. The lowest part of many of these is occupied by a lake, many of which are saline but some are relatively fresh. One of the most puzzling geochemical problems of the Antarctic dry areas is that these lakes have very different chemical compositions. Data on some are given in Table 1. The lakes seem to be of three main types; (1) Lakes which have derived their salts directly from seawater flooding. These are characterised by high Mg^{2+}/Ca^{2+} ratios. (2) 'Sodium chloride lakes' where the principal anion is chloride and the principal cation is sodium. These have a composition which suggests that they have been derived from the concentration of large quantities of glacial meltwater. This type of lake has a Ca^{2+}/Na^{+} ratio ~0.1. (3) 'Calcium chloride lakes' where the principal cations are calcium and magnesium and the principal anion chloride, the Ca^{2+}/Na^{+} ratio being >1. The calcium chloride lakes are generally relatively low in sulphate. The chemical composition of these lakes is perhaps the most difficult to understand.

Table 1 Chemical composition of water samples from the McMurdo dry valley area of Antarctica

	Ca^{2+}/Na^{+}
Inland snow*	0.13
Groundwater†	1.8
Canopus Pond	0.1
Lake Fryxell	0.4
Lake Hoare	0.09
Lake Joyce	0.03
Lake Miers (bottom)	5.0
Lake Vanda	
—upper water (13 m)	1.5
—lower water (61 m)	5.4
Don Juan Pond	10.2
'Amber Ice' at base of Meserve Glacier[13]	1.4
Seawater (for comparison)	0.04

* For example, Ice from Upper Taylor Glacier.
† For example, from surface of frozen water table east of Don Juan Pond.

Examples of lakes with salts of different origin are found in the lakes and ponds of the central Wright Valley. Canopus Pond and the upper waters of Lake Vanda have compositions of the sodium chloride type. However, the adjacent Don Juan Pond and the bottom waters of Lake Vanda have a very different composition, having a much greater proportion of calcium and magnesium chloride (see Table 1).

If the surface area of the glacier is insufficient to balance the ablation/precipitation budget, the glacier will advance further and further below the snow line until the total positive net accumulation above the snow line is balanced by the total ablation below the snow line. Usually the glacier has pushed sufficiently far below the snow line so that some summer melting takes place. In such cases, for a few days during the hottest part of the summer, a stream flows away from the glacier snout and feeds a lake which occupies the lowest point of that particular enclosed drainage basin or flows into the sea. In enclosed drainage basins the size of the lake is determined by that area needed to balance the evaporation/precipitation equation for that particular drainage area. If there is a net precipitation increase to the area the lake levels will rise and if there is a decrease in precipitation the lake levels will fall, provided that the temperature regime always remains similar.

Many of the lakes that occupy the lowest part of the various enclosed drainage basins are chemically stratified and these chemical concentration gradients may contain palaeoclimatic information.

Turning to the problem of the origin of chemical gradients in the saline lakes of the McMurdo oasis, an extreme example is Lake Vanda. The lake is 66 m deep, the lower 20 m being strongly density stratified with the specific gravity rising from 1.005 at a depth of 46 m to 1.10 at the bottom. It is interesting to speculate on the origin of the salt concentration gradient in the lake. Wilson[5] suggested that at some period in the past the climate was such that the Onyx River did not supply appreciable water to Lake Vanda. In these conditions the lake level would have dropped until only a few feet of concentrated calcium chloride remained. When the climate changed, the Onyx would

flow during the summer and fresh water would have flowed on top of this strong salt solution. Since then the salts would have been diffusing upwards. If such a model is assumed, it is possible to calculate the time when this climatic change occurred. On the above assumptions it is possible to calculate that Lake Vanda rose relatively suddenly 1,200 yr ago[5]. This same approach has been used to calculate diffusion ages for Lake Bonney[6,7].

When snow falls on a snow field or land surface it contains small quantities of salts, the principal cations being sodium and calcium and the principal anion being chloride with smaller amounts of Mg^{2+}, K^+ and SO_4^{2-} and other materials. The chemical composition of atmospheric precipitation has been the subject of much study (see refs 8–10). Although the chemicals in precipitation are generally believed to come from the ocean, the actual composition is not merely diluted seawater but has been modified by separation processes at the ocean surface. The actual composition varies as one moves away from the sea due, it is believed, to the existence of two types of aerosol particles in the atmosphere. The first type is large, falls out rapidly and has the composition of bulk seawater. Particles of the second type are very much smaller and have a composition very different from seawater. They have, for example, higher K^+/Na^+ and Ca^{2+}/Mg^{2+} ratios then bulk seawater. Both types of aerosols arise from the bursting of bubbles on the surface of the ocean[8,9]. In order to explain the distribution of salts in Antarctic soils and the composition of Antarctic lakes, the following hypothesis is presented.

Discussion

Over very long periods of time small quantities of snow fall on the land surface and on sublimation leave salts behind. These salts include Na^+, K^+, Ca^{2+}, Mg^{2+}, SO_4^{2-}, Cl^-. It is proposed that fluctuations in relative humidity, due to the occasional snowfall and the summer-to-winter change, cause some of the more deliquescent salts to slowly percolate downwards through the soil. The more deliquescent will reach the frozen water table. At high altitudes, for example, on the top of the Asgard and Olympus Mountains and in the Alatna Valley, only the least deliquescent, for example sodium sulphate, can remain in the soil; the remaining salts, $CaCl_2$, $MgCl_2$ and much of NaCl, eventually reach the frozen water table where during the late summer they move down slope along the surface of the frozen water table. In the more arid situations at lower altitudes, the NaCl (77% equilibrium relative humidity at 0 °C, ref. 11) cannot reach the frozen water table and on the sides of the McMurdo dry valleys; for example, above Don Juan Pond and at similar altitudes along the sides of the Wright Valley, large quantities of NaCl can be found in the 'soils' and under boulders. At higher altitudes in the same region, almost pure Na_2SO_4 and $Na_2SO_4.2H_2O$ can be found in the same position (equilibrium relative humidity of sodium sulphate = 98% at 0 °C, ref. 11). The calcium chloride (equilibrium relative humidity = 44% at 0 °C, ref. 11) and magnesium chloride (equilibrium relative humidity = 38% at 0 °C, ref. 11) eventually move to the lowest part of the drainage system—in the case of the Wright Valley this is Lake Vanda and Don Juan Pond. Thus it is proposed that we have huge geochemical separation systems in the Wright Valley and other Antarctic dry areas, the salt fractionation being controlled by relative humidity and the deliquescent properties of the possible salts that can form from the anions and cations left by evaporated snow. Very saline groundwater can be detected flowing along the surface of the frozen water table in the late summer. For example, groundwater flowing along the top of the frozen water table in the south fork of the Wright Valley in late January 1974 had the following composition: 61,400 p.p.m. Cl^-, 11 p.p.m. SO_4^{2-}, 18,100 p.p.m. Ca^{2+}, 7,000 p.p.m. Mg^{2+}, 9,900 p.p.m. Na^+, 635 p.p.m. K^+ (sample collected by A.T.W. and analysed by A. Field). The groundwater is high in Ca^{2+} with respect to Na^+, and low in SO_4^{2-} with respect to Cl^- and has the chemical composition necessary to explain the origin of the calcium chloride type lakes discussed above.

In the above discussion, relative deliquescence is proposed as the primary mechanism for the separation of water soluble salts in the Antarctic dry areas. For completeness, freezing must also be considered. Eutectic temperature would at first seem to provide an alternative parameter that could regulate the compositition of the liquid phase, and such a mechanism will probably play some part in the initial separations. Evidence that relative deliquescence is the dominating mechanism is provided by the 'calcium chloride' type lakes and the 'groundwater' (see data above) which are not enriched in K^+ with respect to Na^+. This would be expected on the relative deliquescent model proposed (equilibrium relative humidity of 0 °C of NaCl = 77% and KCl = 88%[11]) whereas on an eutectic temperature model the reverse would be expected. When brines of the general composition expected in Antarctic soils are frozen[12], the K^+/Na^+ ratio remains constant until −8.2 °C, at which point sodium sulphate decahydrate forms. The K^+/Na^+ ratio continues to increase with falling temperatures until −22.9 °C at which point sodium chloride dihydrate forms. The ratio further increases until at −36 °C, sylvite (KCl) separates as does the dodecahydrate of magnesium chloride. On an eutectic feezing model, one would have expected potassium to follow magnesium and be enriched in the 'calcium chloride' type lakes and ponds. In fact, the reverse is true, leading one to conclude that it is the relative deliquescent mechanism rather than a freezing or a solubility mechanism which controls the separation of soluble salts in polar deserts.

The 'groundwater' described above can also flow into the sides of glaciers and explains the origins of the clear brown saline 'amber ice' often found in the basal layers of the local glaciers in the Antarctic dry areas (see, ref. 13). It also provides an explanation for the fact that some glacial meltwater streams have a higher Ca^{2+}/Na^+ ratio than the snow falling on their névés.

All the lakes in the Antarctic dry areas in practice have salts entering from both groundwater flow and meltwater from snow and glacier ice. Even glacial meltwater streams seem to have a significant contribution from groundwater salt, particularly early in the season. The fact that the composition of inflow streams varies throughout the summer and does not match the composition of the lake surface waters is an anomaly which is readily explained when the importance of the salt contribution by groundwater is realised. The interfingering of high Ca^{2+} groundwater to its appropriate density level can produce layers of very different Ca^{2+}/Na^+ in a lake. See, for example, the data of Bell[14] for Lake Miers. Layers of high Ca^{2+}/Na^+ ratio presumably contributed by groundwater can be seen at 17 m below the surface, and at the bottom.

Samples collected from the bottoms of Lake Bonney (east lobe) and Lake Vanda contain 14.9 ± 1.1 and 6.4 ± 0.4 tritium units respectively. Surface snow in this area contains about 100 tritium units. This was 'discovered' when I was attempting to provide the New Zealand Institute of Nuclear Science Tritium Dating Laboratory with tritium-free water for calibration purposes. It is generally believed that the bottom of the east lobe of Lake Bonney has been out of contact with the atmosphere for at least 60 yr[7] and the bottom of Lake Vanda for 1,200 yr[5]. As the half life of tritium is 12.3 yr, there should be essentially no tritium present in the bottom waters of either lake. I confirmed that the 'age' of the bottom waters of Lake Vanda is at least 1,000 yr by radiocarbon measurements. If the brine flowing along the top of the frozen water table enters a density-stratified lake it will interfinger to its appropriate density layer; and I propose that this is the mechanism whereby tritium has entered an apparently isolated geochemical system. Note that the inflow of saline groundwater into Antarctic lakes as proposed here would introduce small amounts of carbonate which had been in at least partial equilibrium with the atmosphere. This introduces complications for those attempting to use radiocarbon dating techniques to determine the times at which the lake levels, and hence climate, changed. The interfingering of saline groundwater into Antarctic lakes also provides an additional

mechanism for the formation of chemical stratification over and above that proposed by Wilson[5]. The use of diffusion calculations to determine the times at which lake levels changed must be made with caution with particualar attention being paid to how all the ionic ratios vary with depth.

The rather startling implication of this hypothesis is that much of the million tons of chloride contained in Lake Vanda has entered from groundwater flow. The amounts of Na^+ and SO_4^{2-} needed to bring the overall composition back to that of snow water are to be found in the soils on the lower sides of the valley (as NaCl) and high up on the Asgard and Olympus Ranges (as Na_2SO_4 and $Na_2SO_4.2H_2O$). Such a system would have taken a long time to develop and implies a great age to the Wright Valley geochemical system. A conclusion supported on other evidence[15].

Once the importance of saline groundwater is accepted one can appreciate how certain materials such as the strontium of Jones and Faure[1] can be leached from the glacial debris over which it flows. Thus, the isotopic ratio of the strontium in the sodium chloride type lakes could be of marine origin, whereas the calcium chloride type lakes where the salts are largely of groundwater origin could have components derived from the leaching of rock—which does seem to be the case[1].

The geochemical separation process described here can explain most of the apparently conflicting observations made during geomchemical studies in the Antarctic dry areas and the unusual geochemistry of the area. Such geochemical separation systems have developed in Antarctica and not in other arid parts of the world because the Antarctic dry areas are in a truly rainless desert. The infrequent but violent rains which occur even in the most arid of the non-polar deserts would destroy such a salt separation system. Although the geochemical situation described here is unusual on the Earth as a whole, being restricted to the rainless polar deserts, it may be expected to be found in other parts of the Solar System. For example, one could expect there to be soluble salts on the surface of Mars; and as Mars is also a rainless desert, one could expect simialar geochemical separations to those described here to have taken place.

Much of the work reported here was made possible by grants from the New Zealand University Grants Committee and the cooperation of the New Zealand Antarctic Division, DSIR, the US Navy and US Antarctic Research Program.

Embryonic development of identified neurones: differentiation from neuroblast to neurone

Corey S. Goodman* & Nicholas C. Spitzer

Department of Biology B-022, University of California at San Diego, La Jolla, California 92093

Individually identified neurones are sufficiently large and accessible in grasshopper embryos to permit visualisation and impalement with intracellular microelectrodes from the time of their birth to their maturation. In this article part of the temporal pattern of differentiation from an identified neuroblast (precursor cell) to a group of identified neurones is described.

THE development of nerve cells involves the acquisition of specific neuronal phenotypes. Precursor cells proliferate and give rise to progeny which differentiate into neurones. During neuronal differentiation, processes grow out, arborise and reach their targets where synaptic connections are formed. The neurones acquire a responsiveness to neurotransmitters, an ability to make action potentials and a capacity for their own neurotransmitter synthesis, storage and release. The temporal sequence in which these and other phenotypes appear has not yet been determined for any group of nerve cells *in vivo*. A knowledge of the timing in any one instance would be a useful step in understanding the rules and mechanisms of neuronal development. For example, must the appearance of one specific phenotype precede the appearance of another?

It is possible to identify single unique neurones in the nervous systems of both invertebrates[1–3] and vertebrates[4]; they are usually identified on the basis of their characteristic location, morphology, physiology and biochemistry. Identified neurones are attractive for the study of neuronal development, as it is possible to follow the timetable of single cells from their birth to their maturation, thus avoiding the problems involved in examining the developmental average of a heterogeneous and asynchronous population.

We have been studying the embryonic central nervous system (CNS) of the grasshopper and have focused our attention on the development of the dorsal unpaired median (DUM) neurones because they represent a population of relatively large, identifiable and accessible embryonic cells. The adult CNS of the grasshopper consists of the brain and a chain of segmental ganglia running along the ventral surface of the thorax and abdomen. The DUM cells are a group of identified neurones (80–100) situated on the dorsal surface of the thoracic and abdominal ganglia, near the midline. The properties of the mature DUM neurones are well known from studies of adults[5–11]. The embryonic DUM neurones can be visualised and impaled with intracellular microelectrodes at the earliest stages of their development. Furthermore, the lineage of these neurones can be determined by serial examination of dissected preparations of increasing age, with interference contrast optics, as has been demonstrated for some neurones in the nematode[12,13]. We are now able to write down part of the developmental timetable of some of the identified DUM neurones of the thoracic ganglia in the embryo of the grasshopper. Preliminary accounts of this work have appeared[14,15].

The present study begins with the day 5 embryo, a stage at which the precursor cells (neuroblasts) for the segmental ganglia

have already differentiated from the epidermis. The embryonic nervous system of the day 8 embryo is shown in Fig. 1*A*. At the centre of each body segment are the left and right plates of ventral neuroblasts (Fig. 1*A*iii) which give rise to the chain of segmental ganglia[16–20].

Each ventral neuroblast is ~30 μm in diameter (Fig. 1*A*iv). There are about 31 ventral neuroblasts in each left or right plate. Bate[20] found that the pattern and number of neuroblasts at early embryonic stages was at least as constant as that of the identified neurones of the adult segmental ganglia. Each neuroblast (NB) is a stem cell which will not in itself become a neurone. Rather, each NB maintains its large size while budding off a chain of smaller cells (Fig. 1*A*v). Each of these progeny divides into two cells which are postmitotic and differentiate into neurones. The neuroblasts eventually degenerate at precise times during embryogenesis[20].

Each segmental array of neuroblasts also contains a single unpaired neuroblast, called the median or dorsal unpaired median (DUM) neuroblast, at the posterior end of the segment and dorsal to the paired plates of ventral neuroblasts[16,18,20] (Fig. 1*A*iii, iv, v). As Wheeler[16] first described, the progeny of the single DUM neuroblast extend anteriorly across the dorsal surface of the developing ganglion, quite separate from the neuronal progeny of the ventral neuroblasts. Thus, neuronal differentiation in this lineage can be viewed by removing the embryo from the egg, removing the chain of segmental ganglia from the embryo, desheathing the dorsal surface of the ganglion, and viewing the dorsal surface under a ×40 water immersion lens of a compound microscope with Nomarski interference contrast optics.

The dorsal unpaired median neurones

In the adult grasshopper the somata (cell bodies) of most of the 3,000 neurones in each thoracic ganglion (pro-, meso- and metathoracic) lie on the ventral surface or lateral edge of the ganglion and the neuropil lies dorsal to them. These cells are paired, that is, each cell has a contralateral homologue that is its mirror image. The left and right plates of ventral neuroblasts give rise to these ventral paired neurones[16,18,20]. However, there is a group of 80–100 somata clustered along the midline on the dorsal surface of the ganglion. These neurones, called dorsal unpaired median neurones[7], have the following distinctive characteristics. The cells thus far examined in the adult are unpaired and have medium neurites which bifurcate into bilaterally symmetrical processes. The DUM neurones are the only neurones in the segmental ganglia whose somata generate overshooting action potentials. The soma spikes of the DUM neurones depend on both Na^+ and Ca^{2+} while the axon spikes are predominantly Na^+ dependent[11].

Whereas DUM neurones have certain characteristics in common, many if not all of them can be uniquely identified by their morphology. The largest DUM neurone in the grasshopper metathoracic ganglion (diameter ~40–60 μm) is a unique identified neurone with axons emerging bilaterally in nerve 5 and innervating the extensor tibiae (ETi) muscle in the femur of the leg (this neurone is called DUMETi (ref. 7)).

Only 6–8 of the DUM neurones have large-diameter somata (40–60 μm); most are somewhat smaller (15–30 μm in diameter). The somata of the DUM neurones stain with neutral red[8,9], a dye which selectively stains monoamine-containing neurones in the leech[21] and lobster[22,23]. Both the soma and axons of DUMETi have been shown to contain octopamine[9]. In fact, most if not all of the DUM neurones (particularly the large ones) contain octopamine[24].

Electrical and dye coupling

All cell types examined at early embryonic stages of the grasshopper are electrically coupled to each other; development involves a process of selective uncoupling. Dissected embryos were perfused with a simple saline (NaCl 125 mM; KCl 3 mM; $CaCl_2$ 10 mM; HEPES buffer 5 mM; adjusted to *p*H 7.4). Cells were impaled with intracellular microelectrodes, each with recording and current passing capability. Neuroblasts (~30 μm diameter) had resting potentials of −60 to −80 mV; non-neuronal cells (~10 μm diameter) often had recorded resting potentials of −40 to −60 mV, that may have been the result of damage during impalement. Records made by inserting two microelectrodes into the same ventral or dorsal neuroblast at

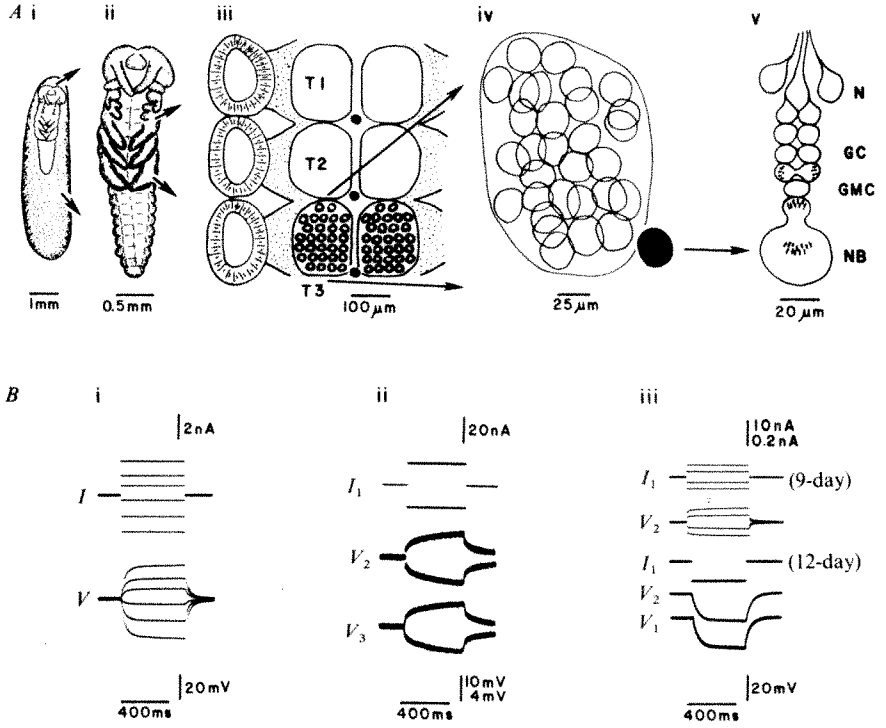

Fig. 1 *A*, Grasshopper embryo (*Schistocerca nitens*) at day 8; diagrams and camera lucida drawings of living specimens. Location of neuroblasts (precursor cells) and formation of neurones are shown (hatching occurs on day 20 at 35 °C[45]). (i) Embryo at day 8 viewed within the egg case. The embryo metabolises yolk, shown stippled. (ii) The day 8 embryo viewed from the ventral surface, showing the three prominent thoracic limb buds and the equivalent segmental appendages forming the mouth parts. (iii) Removal of the thoracic limb buds exposes the paired plates of ventral neuroblasts (enlarged ectodermal cells, open circles), and the single dorsal unpaired median (DUM) neuroblast (filled circles), also called the median (MNB) neuroblast, at the posterior margin of each segmental array of ventral neuroblasts. The contiguous chain of paired plates of neuroblasts gives rise to the chain of segmental ganglia (T1, pro; T2, meso-; T3, metathorax). (iv) Camera lucida drawing of the left hemiganglionic plate of neuroblasts in the metathoracic segment, also showing the dorsal unpaired median neuroblast, viewed with a ×40 water immersion lens and interference contrast optics. (v) A schematic drawing showing a neuroblast (in this case, the DUM neuroblast) as a stem cell; it maintains its large size while budding off a chain of ganglion mother cells (GMC) which each divide into two ganglion cells (GC) and then differentiate into neurones (N). *B*, Input resistance (R_{in}) and extent of electrical coupling of cells at different stages of development of the grasshopper embryo. (i) R_{in} for a ventral neuroblast at day 8 of development (~10 MΩ). Current (*I*) and voltage (*V*) electrodes in the same cell. (ii) Electrical coupling of one ventral neuroblast (I_1) to a second ventral neuroblast (V_2) and to an epithelial cell of the limb bud (V_3), in a day 8 embryo. (iii) Electrical coupling of DUM neuroblast (I_1) to nearby progeny cell (V_2) at day 9 (note large current); DUM neuroblast is still coupled to the rest of the embryo at this stage. Coupling of DUM neuroblast (I_1) to nearby progeny cell (V_2) at day 12 (note small current); DUM neuroblast becomes uncoupled from most of the rest of the embryo at day 10. R_{in} for the DUM neuroblast (V_1) and for the coupled network is ~200 MΩ.

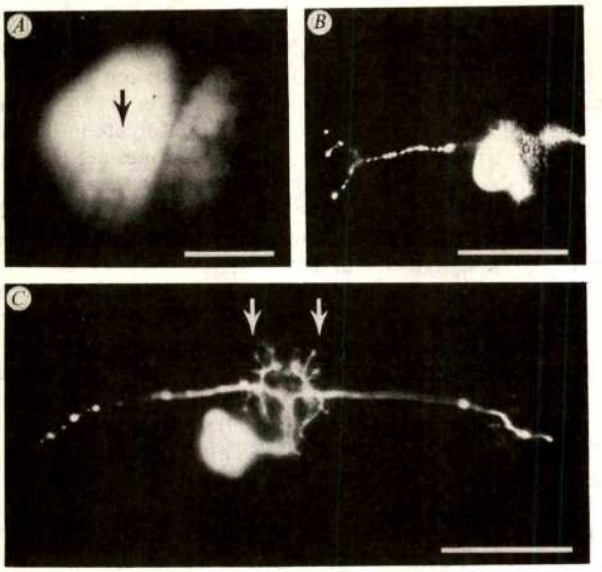

Fig. 2 Lucifer Yellow (450 MW) injections of a neuroblast and two identified neurones of grasshopper embryos. Fluorescence viewed with UV illumination. Scale bar, 100 μm. *A*, Injection of a ventral neuroblast (arrow) in the left hemiganglionic plate of neuroblasts of the metathoracic segment of an 8-day embryo. Dye spreads rapidly through other ventral neuroblasts and some of their progeny in the left plate, and within a few minutes through cells in the right plate. Note absence of spread to adjacent limb buds. *B*, *C*, Injection of identified neurones in the metathoracic ganglion of a 13-day embryo. Cell bodies appear unusually large because of intense fluorescence. The dye does not spread to other cells. Axons are truncated at points of exit from the ganglion. *B*, DUM 3, 4, 5: median neurite bifurcates, and left axon sends branches out nerves 3, 4 and 5 (top to bottom). *C*, DUMETi (DUM 5): axons extend out nerve 5 only. Arrows indicate beginnings of relatively symmetrical central arborisations.

easly stages (Fig. 1*B*i) show that the input resistance (R_{in}) is quite low (~10 MΩ), probably as a result of the extensive electrical coupling. The input resistance of a single ventral neuroblast was found to be about 150 MΩ after mechanically removing it from the network of neighbouring cells to which it was coupled, and impaling it with two electrodes. This is likely to be less than the true value because of possible damage during the isolation.

Ventral neuroblasts are electrically coupled to one another within a hemiganglion (Fig. 1*B*ii). Coupling also exists between left and right hemiganglia, between the DUM neuroblast and ventral neuroblasts, and between neuroblasts of a given segment and those of a segment either anterior or posterior to it. Furthermore, the neuroblasts are coupled to the smaller and morphologically distinct epithelial cells (termed cap cells) which lie just over them, and even to the more distant epithelial cells of the developing limb bud (Fig. 1*B*ii). Confirmation of the positions of the electrode tips and the identities of the coupled cells was achieved by injecting cells with the dyes Fast Green or Procion Rubine (2% dye in 0.25 M KCl). No evidence for rectification of electrical coupling was seen. In all such experiments, the coupling recorded between any two cells disappeared when either intracellular electrode was withdrawn from the cell. Ventral neuroblasts become electrically uncoupled from the limb buds at day 10, but remain electrically coupled to each other until they stop dividing and degenerate by day 15.

We examined the movement of low molecular weight tracers from the interior of one cell to the interior of another by injecting the dye Lucifer Yellow (450 MW), which has a high fluorescent quantum efficiency and rapid rate of diffusion. When iontophoresed into single cells (from electrodes filled with 5% dye in distilled H_2O), it will often spread to other cells to which the injected cell is electrically coupled[25]. When a single ventral neuroblast is filled with Lucifer Yellow in a day 8 embryo, the dye spreads to other ventral neuroblasts and some of their progeny in the hemiganglion within a few minutes (Fig. 2*A*). The fluorescence can be detected in the contralateral hemiganglion shortly thereafter, but spreads to anterior and posterior ganglia much more slowly. However, dye was not seen to spread to limb-bud epithelium, even though the neuroblasts are electrically coupled to the limb-bud cells. In control experiments, dye was not taken up by the cells when simply applied in the bath.

We next examined the electrical and dye coupling of the DUM neuroblast and its progeny. The DUM neuroblast begins dividing at day 6. At first, all of its progeny are electrically coupled to the DUM neuroblast (Fig. 1*B*iii). Until day 9, large currents injected into the DUM neuroblast produce small voltage changes in progeny cells (Fig. 1*B*iii, top), consistent with the extensive electrical coupling of the DUM neuroblast to the rest of the embryo. As early as day 10 (Fig. 1*B*iii, bottom, similar records from day 12) much smaller currents produce large voltage changes in progeny cells. Day 10 is the time at which the DUM neuroblast becomes electrically uncoupled from most embryonic cells other than its own progeny. Input resistance (R_{in}) for the coupled network of neuroblast and progeny (as well as the R_{in} of the DUM neuroblast) increases from <10 MΩ at day 9 to ~200 MΩ by day 12 (Fig. 1*B*iii). All progeny remain electrically coupled to the neuroblast until day 11, when the oldest progeny (identified DUM neurones described below) are first becoming electrically uncoupled. (Mature DUM neurones are not electrically coupled to one another.)

Lucifer Yellow injected into the DUM neuroblast at day 7 spreads throughout all of its progeny. However, at day 8, its

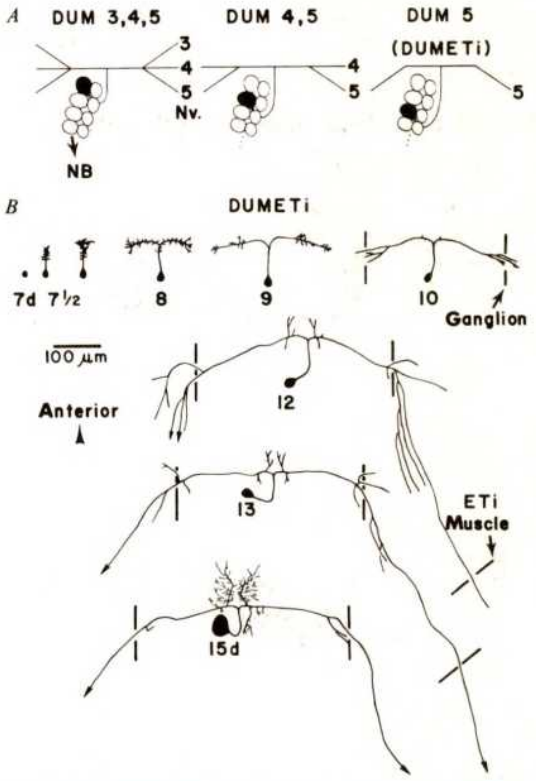

Fig. 3 *A*, DUM neuroblast gives rise to identified DUM neurones. The DUM neoroblast (NB), not shown here, gives rise to chains of progeny; some of the oldest of these progeny become identified DUM neurones. At days 12–13, we find two chains of progeny, generally two cells in width. We have examined the identities of the first three cells on the outside of the oldest chain of progeny ($n = 10$). The morphology of the DUM neurones is revealed by intracellular injection of Lucifer Yellow. In this schematic diagram, the most anterior cell on the outside bifurcates and bilaterally extends out peripheral nerves 3, 4, and 5; the second cell bilaterally extends out nerves 4 and 5; and the third cell extends out bilaterally only nerve 5 (this cell is DUMETi). *B*, Morphological development of the single identified DUM neurone, DUMETi ($n \geq 3$ for each time point). The DUM neuroblast begins dividing at about day 6. Many extra branches and growth cones are produced at the distal end, whether it be in the central nervous system or periphery, and these extra neurites later disappear as the correct branch for DUMETi continues to grow. 'Ganglion' marks the border of the metathoracic ganglion, and 'ETi muscle' marks the proximal boundary of the extensor tibiae muscle in the femur of the limb bud. Arrows mark points of axonal extension beyond the margins of the figure.

oldest progeny are dye-uncoupled. Dye does not spread into or out of these identified DUM neurones, although they are still electrically coupled to other cells (Fig. 2*B*, *C*).

DUM neuroblast gives rise to identified DUM neurones

The evidence that the DUM neuroblast gives rise to identified DUM neurones is described by considering day 12–13 embryos, although these cells can be followed from day 6 by serial examination of dissected preparations of increasing age. Viewing the desheathed dorsal surface of the metathoracic ganglion reveals chains of progeny extending anteriorly from the DUM neuroblast. Cells close to the neuroblast are young progeny which are the result of recent divisions (the neuroblast continues dividing until it degenerates on day 16), whereas those at the anterior (distal) end of the elongating chains are the oldest progeny. The DUM neuroblast is ~30 μm in diameter, the progeny at first are ~10 μm and quickly enlarge to ~15 μm in diameter. Several of the somata increase to a diameter of over 40 μm during embryogenesis. Some of the oldest progeny of the DUM neuroblast become identified as DUM neurones because within a few days they assume the characteristic location (dorsal midline), the characteristic morphology (median neurites which bifurcate and extend bilaterally, Figs 2, 3), the characteristic physiology (spiking somata, Fig. 5) and the characteristic histochemistry (somata which stain with Neutral Red[24]).

At days 12–13, we see two chains of progeny, each being generally two cells in width, with one chain extending anteriorly on the left side and the other chain on the right side of the midline. Initially the older chain is dorsal to the younger (day 7). Between days 7 and 11, the plane in which the two chains lie changes in orientation, from dorso-ventral to horizontal. When the orientation changes, there is a 50% probability ($n = 24$) that the dorsal (older) chain will assume either the left or right position in the horizontal plane. It can easily be distinguished, however, by the morphology of its cells throughout this period (C. M. Bate, C.S.G. and N.C.S., in preparation).

We have examined the identities of the first three cells on the outside of the oldest chain of progeny, and find the same identified neurone in the same position along the chain ($n = 10$) (Fig. 3*A*). The morphology of the DUM neurones is revealed by intracellular injection of Lucifer Yellow, and later visualisation in either living or fixed tissue, with UV illumination (Fig. 2*B*, *C*). (Tissue is fixed in 4% formaldehyde, dehydrated in an ethanol series, cleared in methyl benzoate and mounted in fluoromount.) The most anterior cell on the outside bifurcates and extends bilaterally out as peripheral nerves 3, 4 and 5; the second cell on the outside bifurcates and extends bilaterally out as peripheral nerves 4 and 5; and the third cell on the outside bifurcates and extends bilaterally out only peripheral nerve 5. The axons of this third cell run out nerve 5 to the extensor tibiae (ETi) muscle; this cell is DUMETi. In the mesothoracic ganglion, the first cell also bifurcates and extends bilaterally out as peripheral nerves 3, 4 and 5. Thus, from animal to animal, the cell in the same position along the chain, presumably having the same mitotic ancestry, develops into the same identified neurone.

Morphological development of identified DUM neurones

The outgrowth of processes by the single identified DUM neurone, DUMETi, was followed as a function of developmental age ($n \geq 3$ for each time point). Axonal outgrowth of DUMETi begins on about day 7 with the extension of a median neurite (Fig. 3*B*). At this time, the framework for the neuropil, nerve connectives and peripheral nerves already exists in the form of two longitudinal fibre tracts, two commissures in each segment, and lateral fibre tracts to the periphery. The distal end of the growing axon produces multiple branches with growth cones extending in different directions, often for over 20 μm in the wrong direction. As the correct branch continues to extend and send out branches at its distal tip, the extra incorrect neurites disappear, leaving a relatively naked proximal axon.

By day 8, the axon of DUMETi has bifurcated and both lateral axons appear fuzzy because of the presence of many fine branches. During day 9, the distal end of the axon grows out to the edge of the ganglion, and many of the proximal branches disappear. By day 10, the neurone sends axons out many of the available peripheral nerves and branches of those nerves, even though ultimately these extra branches will disappear and the axon of DUMETi will extend out only nerve 5 (and branch 5b1d) to the ETi muscle. By day 12, the distal axon reaches the ETi muscle. Three prominent features at this age are the occurrence of extra peripheral branches, the start of the central bilateral arborisations and the relatively naked central axon. By day 13, the axon has extended over the entire ETi muscle, but the cell body and arborisations are still relatively small.

After the axon of DUMETi reaches its target, there are three clear morphological changes: the extra peripheral neurites disappear, leaving behind only one axon in nerve 5; the central arborisations greatly increase in the extent and number of their

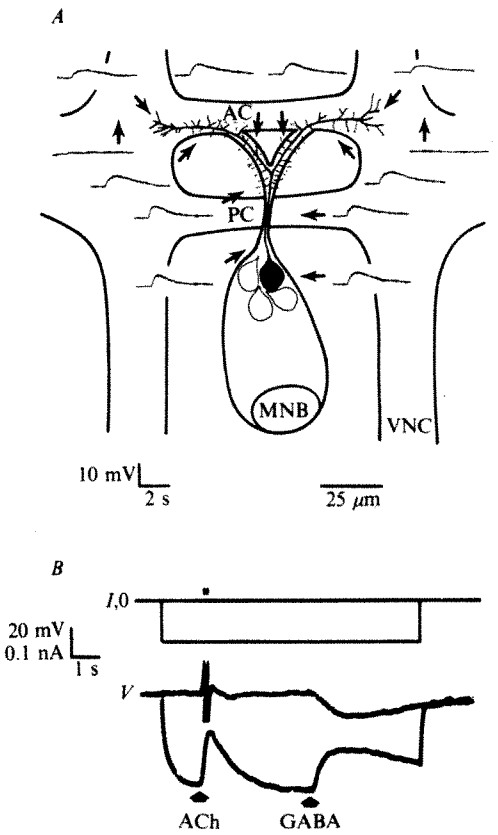

Fig. 4 Chemosensitivity of identified DUM neurones in the grasshopper embryo (the three oldest progeny as described above). *A*, Response to iontophoretic application of ACh in a day 8 embryo. The diagram shows the embryonic neuropil of a single segmental ganglion (T3), as viewed from the dorsal surface (anterior at top). The DUM neuroblast (NB) is shown with its packet of progeny; those most anterior (oldest) send their axons anteriorly in a median bundle of processes which cross the posterior commissure (PC) and bifurcate near the anterior commissure (AC). The extent of branching of an individual neurone was determined by intracellular injection of Lucifer Yellow. The longitudinal connectives extend into the ventral nerve cords (VNC) and are seen on either side. The lateral neuropil extends (beyond the margin of the figure) into three fibre tracts which become peripheral nerves 3, 4 and 5. The response to application of ACh at the points indicated by the arrows were recorded by an intracellular electrode in the cell body. Processes are sensitive to ACh over their whole length. Small vertical or lateral displacements of the iontophoretic electrode abolished the response. *B*, Responses to sequential iontophoretic application of ACh and GABA from a double-barrelled micropipette, recorded with an intracellular electrode in a day 13 embryo. At a resting potential of −55 mV, ACh depolarises the cell to threshold, eliciting overshooting action potentials, while GABA hyperpolarises the cell. When the cell is hyperpolarised by injected current, the response to ACh is larger, but remains subthreshold; the cell is then depolarised by GABA.

fine branches; and the cell body greatly enlarges. A similar initial overproduction of distal branches and eventual disappearance of these extra branches was found also for DUM 3, 4, 5 and DUM 4, 5.

Onset of chemosensitivity

At day 7, neither the DUM neuroblast nor its progeny show responses to bath application of acetylcholine (ACh) or γ-aminobutyric acid (GABA) at 10^{-3} M. In contrast, by 13 days the oldest identified DUM neurones (described above) are sensitive to bath application and iontophoresis of both of these agents. This latter result is illustrated in Fig. 4*B*, which shows the intracellularly recorded responses of a developing DUM neurone to iontophoretic application of ACh and GABA from a double-barrelled electrode. These responses involve a membrane conductance increase (not illustrated). The observed reversal potential for GABA is −70 mV, while the extrapolated reversal potential for ACh lies above +20 mV. The ACh response is abolished by removal of Na^+ (replacement with choline); the GABA response is abolished by removal of Cl^- (replacement with isethionate). The ACh response is reduced by the nicotinic antagonists curare (10^{-4} M), hexamethonium (10^{-3} M) and decamethonium (10^{-3} M); nicotine is an agonist. However, α-bungarotoxin does not significantly reduce the response at 10^{-6} M. The ACh response is unaffected by the muscarinic antagonists atropine (10^{-6} M) and quinuclidinyl benzilate (QNB, 10^{-7} M); pilocarpine has no effect (10^{-3} M). The GABA response is rapidly blocked by picrotoxin (10^{-4} M); muscimol is an agonist.

The oldest DUM neurones first become sensitive to ACh and GABA at day 8 of development, and seem to become sensitive to both neurotransmitters at the same time. Young progeny in close proximity to the DUM neuroblast show no response to iontophoretic application of ACh. In contrast, the oldest progeny at the distal end of the chain, which are still electrically coupled (Fig. 1*B*iii) and already possess neurites (Fig. 3*B*), are depolarised by iontophoretic application of ACh onto their somata. (No desensitisation is seen in response to prolonged application of these agents.)

The processes of the oldest DUM neurone are also depolarised by iontophoretic application of ACh on day 8. Processes seem to be sensitive over their entire length. It seems that chemosensitivity is distributed over the whole surface of the cell, at or soon after the time that it first appears. Identified DUM neurones thus develop chemosensitivity to ACh and GABA while still electrically coupled, and may be sensitive to other neurotransmitters as well. The reversal potential and ionic dependence of the response to ACh and GABA appear similar at days 8, 13 and 18 of development.

Onset of electrical excitability

We have examined the onset of electrical excitability in the oldest DUM progeny by observing the responses of cells to depolarising current pulses injected through an intracellular recording electrode. They are generally incapable of producing action potentials at day 11. They become electrically excitable between days 11 and 12 (Fig. 5*A*), while they are becoming electrically uncoupled. It seemed possible that voltage-dependent channels were not revealed while the cells were electrically coupled because of the long time constant of the coupled network of cells, preventing depolarisation to threshold before channel inactivation occurred. This possibility was tested by exposing the cells to veratridine 10^{-5} g ml^{-1}, which specifically depolarises cells possessing voltage-dependent Na^+ channels[26]. The treatment has no effect on the resting potentials of any of the ventral neuroblasts, the DUM neuroblast, or its progeny up to day 11. In contrast, the oldest DUM progeny are depolarised by the treatment by day 12 (we thank A. Willard for suggesting this approach).

Between days 11 and 12, the oldest DUM neurones first produce small action potentials which fail to overshoot the zero

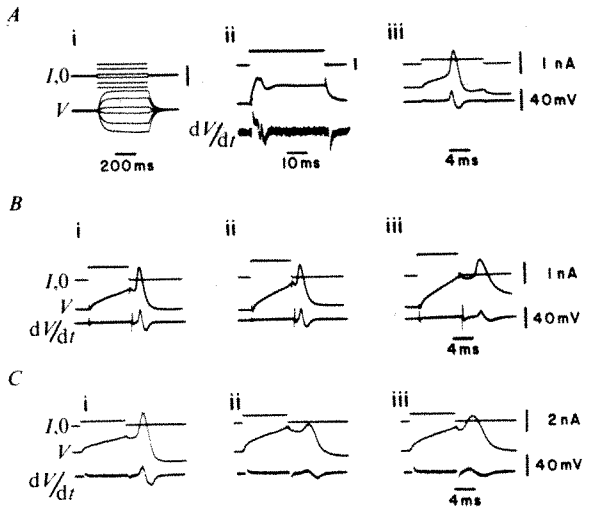

Fig. 5 Electrical excitability of the oldest DUM neurones in the grasshopper embryo. *A*, Responses in the oldest DUM progeny between days 11 and 12. (i) The DUM neuroblast is impaled with one microelectrode to inject current, and an electrically coupled progeny is impaled with a second microelectrode to record voltage. These cells have resting potentials of −50 to −70 mV and appear electrically inexcitable. Depolarisation and hyperpolarisation of the neuroblast and its progeny by 50 mV reveals a constant membrane resistance. (ii) As the cells become uncoupled they develop neurite action potentials in which the inward current is carried predominantly by Na^+ (data not shown). The early embryonic neurites bifurcate at a T-junction, and in many cases the first embryonic axon spikes have the adult characteristic of appearing double-peaked; each peak in the adult and presumably in the embryo corresponds to a separate site of initiation along one of the two lateral axons. (iii) Current injected into a DUM neurone at a later time yields an overshooting action potential that appears to arise in the cell body. *B*, Ionic dependence of the somatic action potential in a day 12 embryo. The overshoot of the spike seen in normal saline (i) is not greatly affected by replacement of Na^+ with Tris (ii) or addition of 30 mM Co^{2+} (iii). *C*, Ionic dependence of the action potential of a DUM neurone in a day 18 embryo. The overshoot (i) is reduced by either removal of Na^+ (ii) or addition of Co^{2+} (iii). In both day 12 and day 18 action potentials, simultaneous removal of Na^+ and addition of Co^{2+} (not shown here) abolishes the action potential.

potential and often have a characteristic double-peaked appearance (Fig. 5*A*). These action potentials are likely to be produced in the neurites, because this response has been shown in adult DUM neurones to be the sum of action potentials arising from two symmetrical neurites distal to the point of bifurcation[10]. These action potentials depend largely on an inward Na^+ current, because they are rapidly blocked by removal of Na^+ or addition of 10^{-9} g ml^{-1} tetrodotoxin (TTX). These cells and those in older embryos are depolarised by 25 mV or more when exposed to veratridine. This depolarisation is blocked by prior removal of Na^+ or addition of TTX.

Within a day, the oldest DUM neurones are capable of producing overshooting action potentials, 2–4 ms in duration, that appear to arise in the cell body ($R_{in} \cong 300$ MΩ). These action potentials depend on Na^+ and Ca^{2+} for their inward current. Removal of Na^+ or addition of 30 mM Co^{2+} (to block Ca^{2+} channels) has little effect on the overshoot (Fig. 5*B*), although simultaneous application of both treatments abolishes the action potential. However, by 18 days, blockage of either inward current reduces the overshoot in these same neurones (Fig. 5*C*). It is known that in at least one adult DUM neurone, DUMETi, the blockage of either inward current alone is sufficient to abolish the action potential[11]. The basis for these developmental changes is not yet known.

Development of later phenotypes

The transmitter of the DUM neurones, octopamine, begins to appear in the thoracic ganglion on day 13, after the axons of the oldest DUM neurones reach their peripheral target[24]. Shortly thereafter, the somata of the oldest DUM neurones begin to stain with Neutral Red.

The first spontaneous synaptic activity, from unidentified synaptic input, is recorded in DUM neurones at 15 days, 1 week after the appearance of chemosensitivity. The source of these synaptic inputs is not yet known.

Temporal sequence of development

There is a distinct order in the acquisition of particular phenotypes by the identified DUM neurones that are the oldest progeny of the DUM neuroblast (Fig. 6). This developmental sequence occurs first in the oldest progeny; younger progeny may be as much as several days behind in their differentiation.

Some of the phenotypes initially express change during the course of further embryonic development whereas others do not. There are changes in the morphology of identified neurones: the initial fine branches and the extra peripheral neurites all eventually disappear. Similarly an initial overproduction and later disappearance of many central branches around the site of the main arborisation has been observed in an identified neurone in the brain of the grasshopper (D. Bentley and A. Raymond, personal communication). In other systems, gap junctions[27] and profiles of chemical synapses[28] appear transiently on cell bodies shortly before the outgrowth of their processes. In the embryonic DUM cells, there appears to be no change in the ionic basis of the responses to ACh and GABA, as indicated by the ion substitution experiments and the reversal potential determinations. In contrast, there is a change in the ionic requirements for electrical excitability of the cell body, consistent with, although not qualitatively as great as, the changes reported for the development of excitability in other neurones[29–33].

The initially extensive electrical coupling and eventual uncoupling are consistent with observations in other embryos[34–36]. The outgrowth of processes and the appearance of chemosensitivity of the identified DUM neurones begin after their terminal mitoses but while they are still extensively electrically coupled. The observation that cells become dye uncoupled before they become electrically uncoupled suggests that there may be some progressive restriction on the molecular size of substances that can pass freely between cell interiors. Further work will be needed to determine the mechanisms involved in these changes and the role of uncoupling in further differentiation.

How general is the sequence of appearance of neuronal phenotypes observed in the DUM neurones? Studies of the development of amphibian spinal cord have shown that Rohon–Beard neurones become electrically excitable a substantial time after their final DNA synthesis[30,37]. They are already depolarised by GABA at this time, but it is not known how early chemosensitivity first appears[38]. The development of electrical excitability of the neurites of embryonic amphibian neurones seems to precede the cell body by a small time interval[33]. The identity of the neurotransmitter of Rohon–Beard cells is not known. The known portion of the developmental sequence for these cells is compatible with the sequence for DUM neurones.

Neurotransmitter synthesis is a relatively early phenotype for vertebrate superior cervical ganglion cells[39,40], whereas it is a relatively late phenotype for invertebrate DUM neurones. However, vertebrate ciliary ganglion neurones show a late large increase in neurotransmitter synthetic enzyme activity after their axons have reached and synapsed on their targets[41]. Neurotransmitter synthesis may differentiate earlier in other neurones in grasshopper embryos, since high levels of ACh are already present by day 5, before differentiation of central neurones[24]. Sanes and Hildebrand[42] found that antennal sensory cells in the pupae of the moth *Manduca* were capable of synthesising and storing ACh before the axons arrived at their targets in the central nervous system. If the onset of neurotransmitter synthesis requires particular environmental cues[43,44], then these cues may exert their influence at different points in the lives of these different types of cells. Alternatively, different types of neurones may simply be reading out different intrinsic programmes.

Further work will be needed before any causal relationship in the sequence of phenotypes of the embryonic DUM neurones can be established or ruled out. However, it is worth noting that several events are closely linked temporally. The outgrowth of processes and the onset of chemosensitivity occur at about the same time. Cells become electrically uncoupled and electrically excitable at about the same time. Neurotransmitter storage is detected just after cell processes have reached their targets. Cell body enlargement, Neutral Red staining, the disappearance of extra peripheral neurites, and the expansion of central arborisations occur at this time. It may now be possible to manipulate one phenotype and examine the consequences for the later expression of others.

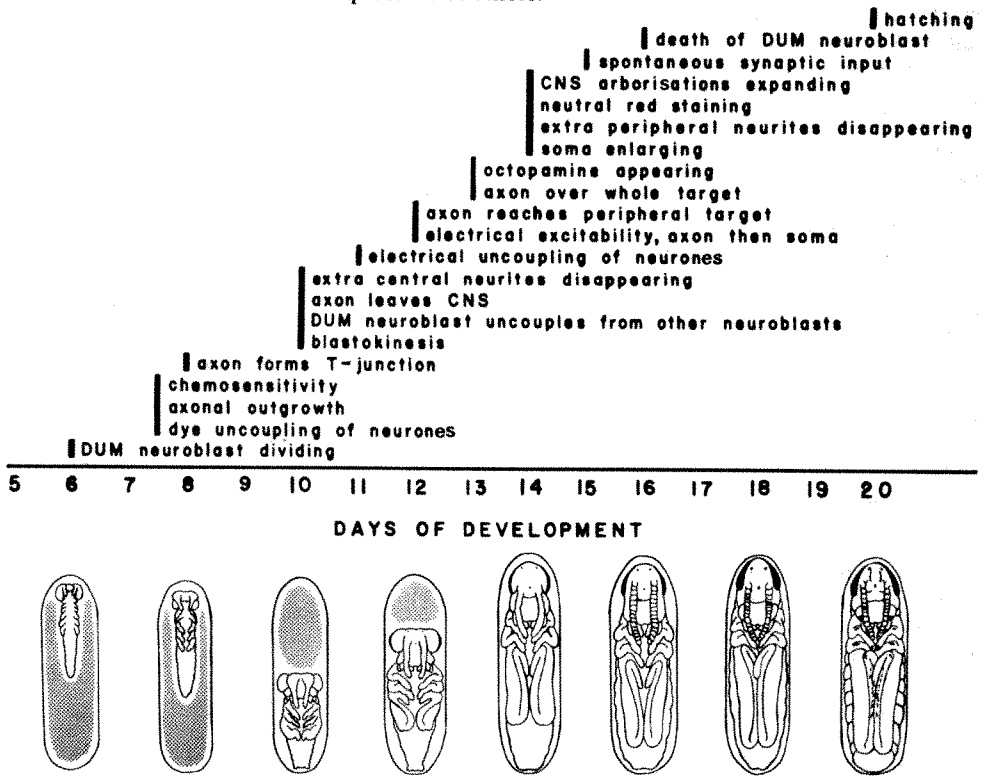

Fig. 6 The developmental timetable for the oldest DUM neurones of the grasshopper embryo *in vivo* [DUM 3, 4, 5; DUM 4, 5; and DUM 5 (DUMETi)]. The egg is laid at day zero, and at 35 °C hatching occurs at day 20. The time of onset or first appearance of a phenotype in these neurones is indicated by a vertical bar. The morphology of the embryo, viewed from the ventral surface in the egg case, is illustrated below as traced from camera lucida projections. Note that the embryo makes a major rotation (blastokinesis) at day 10, and thus from day 10 onward the embryo is viewed from the opposite side of the egg case.

We thank Michael Bate and Michael O'Shea for stimulating discussions, Janet Lamborghini and Darwin Berg for critical reading of the manuscript, William Kristan and Allen Selverston for providing facilities, James Coulombe for technical assistance, and Nino Cooley for preparation of the figures. Bungarotoxin was supplied by P. Ravdin and D. Berg, Lucifer Yellow by Walter Stewart, and QNB by M. Nirenberg and Hoffman-LaRoche. This work was supported by NIH and NSF grants to N.C.S. and a Helen Hay Whitney Fellowship to C.S.G.

Accretion on massive black holes in galactic nuclei

STELLAR collisions and/or tidal break-up of stars by a massive black hole[1–3] accompanied by subsequent accretion of the released gas onto the hole play a crucial part in most black hole models of quasars and active galactic nuclei. It is usually assumed that an accretion disk forms around the hole due to the large orbital momentum of a disrupting star. However, we show here that the accretion mostly has disk characteristics only when $M < M_{cr}$ and becomes quasi-spherical when $M \gg M_{cr}$.

The appearance of the critical mass M_{cr} is determined by the fact that the reservoir of the accreting matter is replenished discretely. Moreover, the time scale between two stellar break-ups τ_d (determined by the consumption rate) does not generally coincide with the evolution time scale, τ_{evol}, of the first star remnant. If $\tau_{evol} < \tau_d$, the accretion of this remnant ceases before the next star can be disrupted. Hence an accretion disk will form producing a rather discrete picture in time. Whenever $\tau_{evol} \gg \tau_d$ many other stars will be disrupted during the evolution of the first star's disk debris, producing remnants orientated randomly in space. Collisions between these remnants will lead to the more or less spherical shape of the resulting gas cloud, and its accretion onto the black hole will proceed in this nearly spherical region.

On considering quantitative details we first obtain the evolution time scale τ_{evol} for the disk remnant of a disrupted star (called 'disk' here). After tidal break-up of a first star (which may be accompanied by its thermal flare[4] the gas remnant expands and after one or few revolutions around the hole, that is the time scale $\tau_{form} \approx 3\times10^2(M_h/10^6M_\odot)$ yr forms an elliptical disk with axis depending on both energy and angular momentum of the orbiting star. If they are conserved after the disruption of the star, the minimal and maximum distances of the disk boundary are related by

$$\frac{r_{min}}{r_{max}} = \frac{a(1-e)}{a(1+e)} \approx \frac{1}{2}(1-e) \qquad (1)$$

Here $e \approx 1$ is the eccentricity of the disk; r_{min} is of the order of the tidal radius $R_t = 2.2r_*(M_h/m_*)^{1/3} \approx 1.5\times10^{13}M_6^{1/3}$ cm for a black hole of mass $M_h = 10^6M_6M_\odot$; $r_{max} = (4/3)r_*M_h/m_* \approx 10^{17}M_6$ cm; $m_* \approx 1M_\odot$ and $r_* \approx 1R_\odot$ are the typical stellar mass and radius. Therefore, $1-e^2 = 6\times10^{-4}M_6^{-2/3}$, and the semi-axis of the disk are

$$a = \tfrac{1}{2}r_{max} \approx 5\times10^{16}\mathrm{M}_6 \text{ cm}$$
$$b = a(1-e^2)^{1/2} \approx 1.2\times10^{15}M_6^{2/3} \text{ cm} \qquad (2)$$

Viscous friction causes the disk to accrete gradually on to the hole. This accretion proceeds in the optically thick manner. The viscosity in the disk is determined mainly by turbulent transfer processes, so we may write $\nu = v_t l$, where v_t is the velocity of turbulent motions, and l is the free path length. The value of l is approximately equal to the disk's half-thickness $H = rv_s/v_\varphi$ (v_s is the sound velocity and $v_\varphi = (GM/r)^{1/2}$ is the keplerian velocity). Assuming $v_t \approx v_s$, one obtains $\nu \approx rv_s^2/v_\varphi$ which by a factor ~1 coincides with the Ichimaru's theory of magnetohydrodynamic turbulence in the accreting disk[5]:

$$\nu = \left(\frac{2}{\pi}\right)^{3/2}\left(\frac{kT}{m}\right)^{1/2}H$$
$$H = 1.18r\left(\frac{GM}{r}\right)^{-1/2}\left(\frac{2kT}{m}\right)^{1/2} \qquad (3)$$

(m is the ion mass). The rate of viscous dissipation per unit

0028–0836/79/290214—02 $01.00

© Macmillan Journals Ltd 1979

volume is $\varepsilon_\nu = \frac{1}{2}\nu\rho r^2(\partial\Omega/\partial r)^2 \sim \Sigma(kT/m)^{1/2}\Omega^2(\rho, \Sigma = 2H\rho$, and Ω being volume density, surface density, and angular velocity respectively). The maximum rate of viscous dissipation is reached in the outer domain of the disk near the radius

$$R_m = 1.2\times10^{13}M_6^{1/3}\dot{M}_{-6}^{2/3}\ \text{cm} \quad (4)$$

($\dot{M}_{-6} = \dot{M}/10^{-6}M_\odot\ \text{yr}^{-1}$) from when the bound–free and free–free absorption dominate the electron scattering opacity. In this region ($r \geqslant R_m$) the balance between the rate of viscous dissipation and the rate of radiative loss yields the temperature of plasma in the disk

$$T = 4.4\times10^4M_6^{1/4}\dot{M}_{-6}^{3/10}r_{13}^{-3/4}\ \text{K} \quad (5)$$

From equations (3) and (5) we find the viscosity coefficient

$$\nu = 8.5\times10^{15}M_6^{-1/4}\dot{M}_{-6}^{3/10}r_{13}^{3/4}\ \text{cm}^2\ \text{s}^{-1} \quad (6)$$

Knowing the main parameters of the steady state disk (including the dependence of ν on r) enables us to simulate the secular evolution of the viscous disk following the model of Lynden-Bell and Pringle[6]. The mass of the disk diminishes as it accretes on to the black hole according to the law $m = m_i(1 + t/\tau_{evol})^{-2/5}$ where $m_i \approx 1M_\odot$ is the initial disk mass, R_i is its characteristic size, and

$$\tau_{evol} = \frac{32}{75}\frac{R_m^{3/4}R_i^{5/4}}{\nu(R_m)} \approx 5.4\times10^5M_6^{1.84}\ \text{yr} \quad (7)$$

is the evolution time scale. In equation (7) we use $R_i = (ab)^{1/2}$ to account for the elliptical disk form and adopt $\dot{M} = m/\tau_{evol}$ in equation (4). A more approximate, but essentially the same estimate for

$$\tau_{evol} \approx \Sigma/\dot{\Sigma} \approx \Omega\left|\frac{\partial\Omega}{\partial r}\right|^{-1}\frac{r}{\nu}\Bigg|_{r=R_i} \approx 1.8\times10^6M_6^{1.84}\ \text{yr} \quad (8)$$

is obtained from time-dependent equations for disk accretion.

Now, comparing τ_{evol} from equation (7) with the time scale τ_d between successive tidal disruptions of two stars[1]

$$\tau_d \approx 5\times10^2M_6^{-4/3}v_{200}n_7^{-1}\ \text{yr} \quad (9)$$

we obtain for the critical black hole mass

$$M_{cr} \approx 1.1\times10^5n_7^{-0.32}v_{200}^{0.32}M_\odot \quad (10)$$

For conditions similar to those in the nucleus of our Galaxy (star density $n \approx 10^7\ \text{pc}^{-3}$, velocity dispersion $v = 200\ \text{km s}^{-1}$) we find $M_{cr} \sim 10^5M_\odot$, and for a dense globular cluster ($n = 5\times10^4\ \text{pc}^{-3}$, $v = 20\ \text{km s}^{-1}$)$M_{cr} \sim 3\times10^5M_\odot$ is obtained.

At $M < M_{cr}$ the disk evolves faster than the next star enters the Roche lobe of the black hole. Therefore when the black hole mass is small enough, the accretion takes place in the disk regime and ceases before the next star breaks up. As follows from equation (7), at $t \leqslant \tau_{evol}$ the accretion rate exceeds Eddington critical rate $\dot{M}_{Edd} \approx 2\times10^{-2}M_6$ ($M_\odot\ \text{yr}^{-1}$) if the black hole mass $M_h < 4\times10^4M_\odot$. For smaller masses the fact that the accretion rate $\dot{M}$ is proportional to $t^{-7/5}$ is very critical during the time interval $t_s \approx 7M_4^{2.03}$ $\tau_{evol} = 0.8\times10^3M_4^{-0.19}$ yr. However, the accretion keeps its disk character as the luminosity of the hole $L \leqslant (0.6-1.0)L_{Edd}$ (ref. 7). Mass outflow from the disk is possible during t_s, but the value of t_s is negligible compared with τ_d (equation (9)) if $M_4 \leqslant 1$. As for the smaller black hole masses, we believe that at $M_h < 10^4M_\odot$ the tidal disruption of stars is not the main fuel for black holes in galactic nuclei.

When $M \approx M_{cr}$, the characteristic time scales τ_{evol} and τ_d are of the same order of magnitude. In this case and especially when $M > M_{cr}$, star–disk collisions shorten the time scale τ_d. The accumulation of star remnants around the black hole leads to the spherisation of the resulting cloud and to the subsequent quasi-spherical accretion. So when $M \gg M_{cr}$, we may assume that the accretion will be quasi-steady with the rate equal to that of stellar consumptions, analogous to the case of accretion on to a compact object in close binary systems where the accretion rate is controlled by matter outflow rate from the normal star.

We have assumed, in accordance with most models, that the accreting gas is fuelled by tidally disrupted stars. However, there are three other possible sources of this gas: (1) gas loss by stars during their evolution; (2) star collisions; (3) accretion of intergalactic gas.

As for the source (1), the present rate of gas loss by stars in the galactic nuclei is of the order of $M^{-1}\dot{M} \sim 10^{-12}-10^{-11}\ \text{yr}^{-1}$ (refs 8, 9). This gas probably has a large angular momentum and forms a disk which supplies the black hole with gas at a rate less than 10^{-4}–$10^{-5}M_\odot\ \text{yr}^{-1}$ when the total mass of stars in the nucleus is 10^7–$10^8M_\odot$. The real accretion rate seems to be much smaller as part of gas transforms into young stars, and another part is expelled from the nucleus by supernovae explosions. (As an example, the nucleus of our Galaxy shows evidence both of increased number of young stars and of supernova remnants.) It is easily seen that at $M_h \ll 10^4$–$10^5M_\odot$, gas lost by stars may become the main fuel for the black hole, but the accretion remains in a disk regime.

In contrast, when the black hole mass is large enough ($M_h > 2\times10^7n_7^{1/2}r_c^{3/4}M_\odot$, the core radius, r_c, (pc)) the breakup of stars by collisions begins to dominate the tidal disruptions. In this case the evolution time for a disk formed (which may be estimated analogous to equation (7)) seems to be much larger than the time interval between successive collisions, so that the accretion remains quasi-spherical.

Only when the main source of the accreting gas is the flow of intergalactic gas which has a very large angular momentum relative to the galactic centre, is the accretion expected to have a disk character irrespective of the black hole mass. However, the intergalactic reservoir of gas may, in principle, be distinguished from the intragalactic reservoir as in nuclei of galaxies belonging to a close pair or group, the activity is expected to be simultaneous (coincidence scheme)[10]. It is possible that some point radio sources in the nuclei of elliptical and spiral galaxies which are members of the same groups or pairs[11,12] show evidence for the accretion of intergalactic gas or flow of outlying clouds.

Observation of large 2.2 μm polarisation in 3C345

INFRARED polarisation observations of the quasars 3C345 and 3C273 are reported here. The highly polarised and variable optical emission of BL Lacertae objects is correlated with similar high polarisation and variability in the IR, and is clearly the product of non-thermal processes. IR polarisation by dust, or by a combination of dust and non-thermal processes, is also found in Seyfert galaxies[1–5]. These observations suggest that the measurement of IR polarisation in quasars be used to investigate the often dominant IR emission in these sources. However, so far only one measurement of polarisation at wavelengths as long as 2.2 μm in a quasar, 3C273, has been reported[4].

© Macmillan Journals Ltd 1979

A clear distinction exists between the variable, steep slope QSOs which often show strong and variable optical polarisation, and the less variable QSOs with lower spectral index which do not[6,7]. The former resemble the BL Lac objects in the steepness of their optical spectra and in their optical polarisation. 3C345 is such a quasar with variable visual and IR flux[8] and highly variable visual polarisation[9,10]. 3C273 may vary somewhat on a long time scale, but this slow (if present at all) variation and the small optical and IR polarisation suggest that 3C273 is a member of the latter group. As these two quasars seem to show different phenomena, we have observed them in order to compare their IR polarisation.

Linear polarisation at 2.2 μm was measured with a chopper-coupled polarimeter (to be described elsewhere[11]) at the Kitt Peak National Observatory 4-m telescope. The sensitivity to polarisation is a function of both the intensity and polarisation of the sources; as a rough guide, in one hour of integration time 1% polarisation can be measured on a source with K magnitude of 11 at the 4-m telescope. Instrumental polarisations were measured to be 0.42% (J, 1.25 μm), 0.38% (H, 1.6 μm) and 0.12% (K, 2.2 μm). The data were corrected for this effect by subtraction of the appropriate Stokes parameters. A further correction was made for the polariser efficiency determined by measurement of the transmission of crossed polarisers.

The position angle was calibrated by observing the polarisation of VI Cyg 12 and computing the difference between the measured angle, as determined by the arbitrarily positioned polariser, and the angle at K of $\theta = 113°$ determined by Dyck and Jones[12]. The K polarisation that we found for VI Cyg 12, $P_K = 1.39 \pm 0.04\%$, is in reasonable agreement with the Dyck and Jones measurement of $P_K = 1.22 \pm 0.12\%$.

We first observed 3C345 on 5 May 1977 (Table 1). Very large 2.2 μm polarisation of $20.6 \pm 7.2\%$ was noticed at that time, but because the signal-to-noise ratio did not give a completely convincing result, we felt that the measurement required corroboration. This became possible in April 1978 (Table 1), and this time 3C345 was observed on three nights. The 2.2 μm polarisation was again very large. The magnitudes of the polarisations are close to those found in the previous year and the orientations also seems similar. However, this agreement may well be coincidental as the IR polarisation may be variable as is the visual. Further observations are required to establish IR variability.

Remarkably, the IR polarisation of 3C345 is much greater than the visual. The visual measurement that was made on 25 April (at the same time as the two IR measurements of that night) was noisy because of sky background but established an upper limit to the B (0.44 μm) polarisation of 6%. The measurements of 26 and 27 April are consistent with this result. They also show that despite being much smaller in magnitude, the visual polarisation had approximately the same orientation as the IR on the previous nights.

In extragalactic sources in which polarisation has been measured, the IR polarisation is either equal to (for example, BL Lac)[1] or less than (for example, MK421, NGC4151)[2] the visual polarisation. High IR polarisation accompanied by much smaller visual polarisation is a as yet a phenomenon unique to 3C345 amongst extragalactic objects.

Table 1 Polarisation measurements of 3C345 and 3C273

Object	Date	λ (μm)	$P \pm \delta P$	$\theta \pm \delta\theta$
3C345	5 May 1977	2.2	20.6 ± 7.2	32 ± 10
	23 April 1978	2.2	23.8 ± 6.4	67.0 ± 7.5
	24 April 1978	2.2	21.9 ± 4.2	65.4 ± 5.5
	25 April 1978	0.44 (B)	< 6	—
		1.6	9.7 ± 6.1	—
		2.2	32.6 ± 6.5	65.0 ± 5.6
	26 April 1978	0.44 (B)	4.5 ± 0.7	68 ± 9
	27 April 1978	0.44 (B)	2.2 ± 0.7	43 ± 19
3C273	5 May 1977	2.2	0.07 ± 0.23	—

We have observed 3C273 intermittently since 1975, and observed it again in April 1978. In April 1978 we observed the source with the new instrument and obtained a much lower limit on the polarisation than in our earlier studies. The formal measurement (Table 1) of $P_K = 0.07 \pm 0.23\%$ corresponds to an upper limit (2σ) of 0.46%. This is consistent with the possible detection of $P_K = 0.33 \pm 0.14\%$ of Kemp *et al.*[4]. Thus 3C273 does not seem to be an object with active IR polarisation.

Optical polarisation of 3C345 has been studied for more than a decade. These data and the radio polarisation have been reviewed by Kinman[10]. Between 1967 and 1974 the optical polarisation varied between 1% and 12% and was accompanied by position angle fluctuations of 20°–110°. Kinman suggests that the position angle shows some regularity, lying between 80° and 110° during 'outbursts' of high flux, and this direction may be related to the position angle of super-relativistic expansion, $105° \pm 5°$. Stockman *et al.* have also suggested an alignment of the optical and radio components[13]. During our observations, however, the apparently parallel visual and IR polarisation directions were not aligned with the expansion direction.

The spectrum and variability of 3C345, and now the polarisation, suggest that the IR emission is non-thermal. Polarisation by scattering off dust seems unlikely to give the observed wavelength dependence. It would probably be difficult for any scattering mechanism to account for the large IR polarisation unless there is very great asymmetry. The synchrotron mechanism can give large visual and IR polarisation, although the peculiar wavelength dependence remains to be explained.

Any explanation for the wavelength dependence of the IR polarisation based on Faraday rotation is unlikely for several reasons. First, in optically thick sources, the polarisation tends to decrease towards longer wavelengths, opposite to the sense found in 3C345 (ref. 14). Second, in this mechanism the 2.2 μm and visual polarisation parallelism would be unaccounted for. And third, Faraday rotation at IR wavelengths would require larger fields and densities than are generally encountered in similar sources.

It may be more plausible to look for a dilution mechanism because the approximate parallelism of the IR and visual polarisations suggest that the IR and optical sources are related. However, spectra of 3C345 taken by Wampler[15] do not show emission lines in the B passband strong enough to dilute continuum polarisation. Wampler also showed that the absence of a Balmer break indicates that thermal continuum emission is unlikely to be strong in 3C345.

An explanation may lie in the models of optical polarisation of Kinman *et al.*[9]. They suggest that three sources contribute to the polarisation. Two of these, one a slowly and one a rapidly varying component, are assumed to be polarised by approximately 17%, but in unrelated directions. Then as intensity variations occur, the sum of the polarisations combines to give the observed 2–11% variations. The IR polarisation that we observed is close to Kinman *et al.*'s value of 17% for the components. The observed wavelength dependence of polarisation would result if, for example, the slowly varying component extends from the visual to the IR, and the rapidly varying component, perhaps with flatter slope, interferes with the visual, but not the IR polarisation. Some support for a multicomponent model is found from the observed dual component structure in the radio. The agreement of the two measurements separated by a year implies that the IR polarised component is only slowly varying.

The high degree of IR polarisation places 3C345 among the 'violent variables' shown by Nordsieck[16] to occupy the upper right portion of a plot of polarisation against spectral index. The polarisation requires a high degree of order in the magnetic field. From Nordsieck's equations we find his parameter δ describing the 'squash' of the magnetic field (where $P(H, \chi) = P_I[H_x^2/(1+\delta^2) + H_y^2/(1-\delta^2)]^{1/2}$ is the probability that an element of volume has a field H perpendicular to the line of sight in direction χ) is $\delta \approx 0.5$ (with spectral index 1.2). Similarly the ratio of a directed field to an isotropic field (Nordsieck's case IIa)

is $\varepsilon/H \approx 0.4$. Evidently considerable long-range order exists in the source.

The detection of strong IR polarisation in a quasistellar source presents another point of similarity between quasars and BL Lac objects. IR polarisation measurements can evidently provide insights into the structure and emission mechanisms of quasi-stellar objects, especially the optically active ones which often also have steep slopes. IR and visual polarisation activity seems to be correlated in quasars as it is in BL Lac objects. However, as an example with greater polarisation in the IR than in the visible has now been found, it may be useful not to preselect these objects by optical polarisation criteria alone; non-thermal sources that may be partially obscured by other visual emission may appear in the IR.

We thank Jeffrey Moller for many contributions to this project, including the computer interfacing and software, and N. Jones-Knacke for helpful comments. High-pressure $(Mg, Fe)_2SiO_4$ phases in the Tenham chondritic meteorite

THE high-pressure phase transformations of olivine $(Mg, Fe)_2SiO_4$ are of fundamental importance to the dynamics of the mantle[1–3]. Experiments[4] have demonstrated that at high pressure olivines transform to a solid solution series of (Mg, Fe) spinel (γ phase), while in olivines with Mg/Mg+Fe ratios greater than 0.85, 'modified' spinels with an orthorhombic structure (β phase) are formed[5]. The β phase in pure Mg_2SiO_4 is considered to have a stability field at pressures intermediate between those of olivine and the γ spinel phase, although the possibility that it forms as a metastable quench product from γ spinel has not been entirely ruled out. A central issue is the mechanism and hence the kinetics of these transformations but no such experimental work has been carried out. Details of the mechanisms involved may be inferred from experimental results, but available natural samples of high-pressure $(Mg, Fe)_2SiO_4$ polymorphs are confined to shock-produced

Table 1 Electron microprobe analysis of purple ringwoodite and olivine from the Tenham chondrite

phases in chondritic meteorites (for example, Tenham, Coorara, Catherwood and Coolamon[6–10]). Binns *et al.*[6] first reported the X-ray diffraction evidence for the existence of natural γ spinel in the Tenham chondrite where it occurs as small ($\approx 100\ \mu m$), purple grains within shock-produced veins. The natural γ spinel is termed ringwoodite. Shock-wave experiments by Jeanloz and Ahrens[11] have failed to produce a spinel phase, and recently Jeanloz[12] has claimed, from X-ray powder diffraction, IR and optical data that ringwoodite is a complex aggregate of goethite, majorite garnet and γ iron, mis-identified as the spinel phase by previous workers. Here we present definitive evidence from electron-probe microanalysis, transmission electron microscopy and diffraction on the true nature of the purple grains (termed ringwoodite) in the Tenham chondrite.

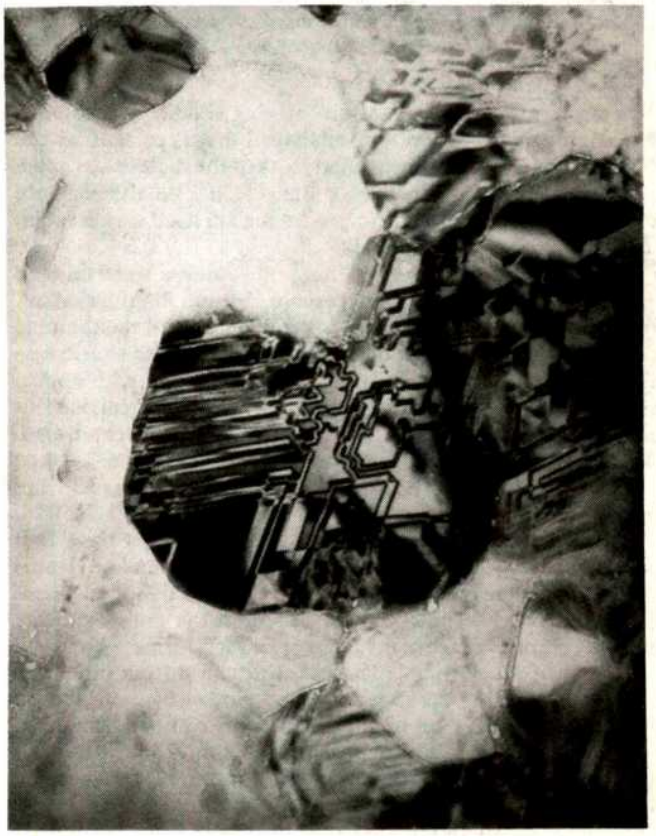

Fig. 1 Transmission electron micrograph of one crystal from a polycrystalline intergrowth formed by the transformation of olivine to γ spinel. The antiphase and twin boundaries within the crystal are due to the inversion of γ spinel to the β 'modified' spinel phase. Other crystals in this section are tilted out of contrast (magnification, ×140,800).

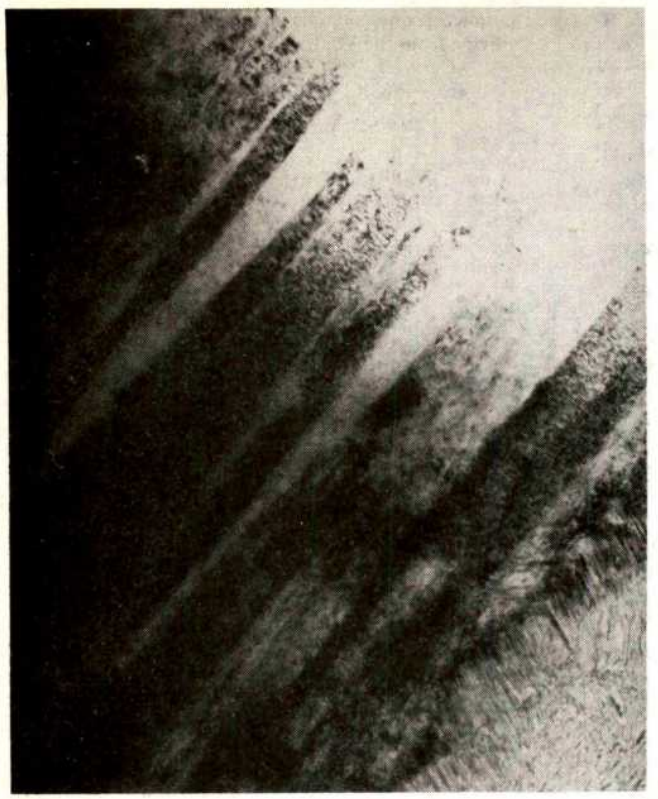

Fig. 2. Transmission electron micrograph showing the second type of morphology produced by the olivine to γ spinel transformation. The twin-related plates lie on {111} planes of the γ spinel structure. Subsequent inversion to the β 'modified' spinel phase has produced the very fine antiphase domains within the plates (magnification ×60,200).

Electron microprobe analysis of ringwoodite indicates a composition identical, within analytical error, to that of the olivine in the relatively unshocked parts of the meteorite (Table 1). This agrees with the results of Binns *et al.*[6]. Analyses do not vary significantly from grain to grain which in itself suggests that a complex aggregate is unlikely.

Optically thin sections containing ringwoodite were thinned for transmission electron microscopy by ion bombardment. Observations were recorded after various stages of the thinning process and a complete traverse made through the shock vein into the ringwoodite. Correlation of thinned areas with optical micrographs ensured that TEM observations were carried out on the purple grains where the composition has been confirmed. Electron petrographical observations of the microstructure and phase assemblages of the shock vein will be reported in full elsewhere.

Transmission electron microscopy and diffraction show that the purple ringwoodite consists of a polycrystalline spinel aggregate partially inverted to the β 'modified' spinel phase (Figs 1 and 2). The microstructures within the grains indicate that the β phase is an inversion product formed by rapid quenching of the γ spinel. The transformation from olivine to the original γ spinel has apparently taken place by two different mechanisms leading to spinel grains with distinctly different morphologies: first, as equant subregular intergrown crystals (grain size $\approx$1,000 Å) (Fig. 1) and second as twin-related parallel plates on (111) planes of the spinel structure (Fig. 2). The former morphology indicates an independent nucleation and growth mechanism while the latter suggests a cooperative shear mechanism with some of the characteristics of a martensitic transformation. As the transformation from olivine to spinel involves a change in the close packing of oxygen atoms, the mechanism may be dependent on the orientation of the original olivine crystal with respect to the shock-wave front. No previous observations of possible mechanisms have been made, although Sung and Burns[3,13] have emphasised nucleation and growth in attributing deep-focus earthquake genesis to this transformation. It is questionable whether the possibility of a martensitic mechanism would enable the necessary overpressures to be generated for an implosive transformation.

The subsequent inversion of γ spinel to the orthorhombic β 'modified' spinel phase on quenching requires no change in the oxygen packing and involves a redistribution of the cations[5,14]. Thus the original γ spinel grain boundaries and the twin-related oxygen packing distribution (Fig. 2) are preserved. The relationship between the two structures introduces a very large number of translational and orientational variants leading to a complex anti-phase and twin domain structure within the grains (Figs 1 and 2). Electron diffraction patterns show splitting of the main spinel reflections due to the formation of twin domains of lower symmetry. Weak superlattice reflections are also observed which are consistent with the formation of the $a \times \sqrt{2}a \times a/\sqrt{2}$ body-centred orthorhombic cell of the β phase (where $a \approx$ 8.2 Å, the lattice parameter of the γ spinel). The fine scale of the microstructure within the grains indicates that the nucleation of the β phase has occurred during a relatively rapid quench. There is no evidence in the microstructures or the diffraction patterns to suggest that the γ spinel phase was formed from olivine through any intermediate stage. The similarity between the β phase and γ spinel results in very similar X-ray powder patterns, that is predominantly that of spinel, with some extra lines. IR spectra will also indicate some similarities to spinel although with a significantly lower structural symmetry. Jeanloz' recent X ray and IR data[12] are consistent with our observations that the purple grains are a γ spinel–β phase intergrowth.

The quench texture of the β phase again raises the question of its thermodynamic stability. Direct experimental evidence can be obtained by either studying the transformation *in situ* at high pressures, or more easily by observing the microstructures preserved in quenched experiments. Such TEM studies have yet to be carried out. Note, however, that the γ–β transformation has many of the characteristics of the formation of metastable transitional phases in non-equilibrium processes. A direct transformation from γ spinel back to olivine on pressure and temperature reduction involves a major structural change with a large activation energy. Metastable phases formed as kinetically more favourable alternatives are invariably modifications of the parent phase and involve minor structural reorganisation and a reduction in translational symmetry[15]. The β phase has these characteristics.

The purple grains in the Tenham chondrite described here represent the first reported natural occurrence of β-$(Mg, Fe)_2SiO_4$. Following Ringwood and Major[4], we suggest that this β phase in nature be termed Wadsleyite.

We thank Drs S. O. Agrell and J. D. C. McConnell for discussions and I. C. Marshall for specimen preparation. Financial support was provided by the NERC.

New phyllosilicate types in a carbonaceous chondrite matrix

CARBONACEOUS chondrites provide valuable information as they are the least altered examples of early Solar System material[1]. The matrix constitutes a major proportion of carbonaceous chondrites. Despite many past attempts, unambiguous identification of the minerals in the matrix has not been totally successful[2]. This is mainly due to the extremely fine-grained nature of the matrix phases. Recently, progress in the characterisation of these phases has been made by electron diffraction studies[3,4]. We present here the direct observation, by high resolution imaging, of phases in carbonaceous chondrite matrices. We used ion-thinned sections from the Murchison C2(M) meteorite for transmission electron microscopy. The Murchison matrix contains both ordered and disordered intergrowths of serpentine-like and brucite-like layers. Such mixed-layer structures are new types of layer silicates.

For an unknown mineral, electron diffraction patterns from a number of principal crystallographic zones are a sufficient (although not necessary) means of identification. However, selected area diffraction patterns of phyllosilicates from the Murchison matrix are of poor quality because of the small sizes of individual grains. Good images, on the other hand, can be obtained. Interpretation of these images is based on previous investigations of Murchison[5], and on images from related high-resolution transmission electron microscopy (HRTEM) studies of terrestrial phyllosilicates[6–9]. Phyllosilicate structure types may be identified by their characteristic (001) basal spacings when viewed parallel to their sheets[10]. For example, serpentines show a basal spacing of 7.3 Å, while micas and talcs have a layer repeat of 10 Å (ref. 11).

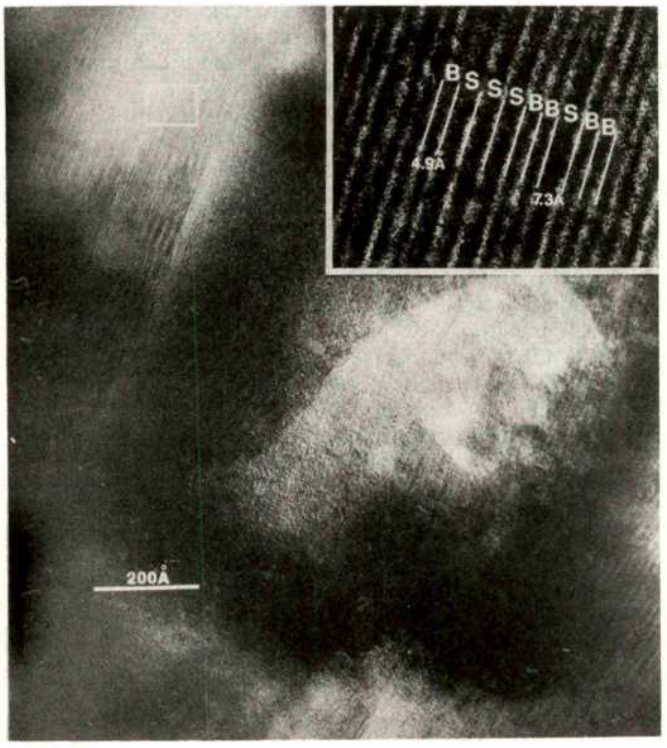

Fig. 1 A HRTEM image showing basal fringes in several mixed layer silicate crystals within the matrix of the Murchison carbonaceous chondrite. The inset is an enlargement of a portion of the same area which reveals a disordered arrangement of serpentine- (S) and brucite-type (B) layers.

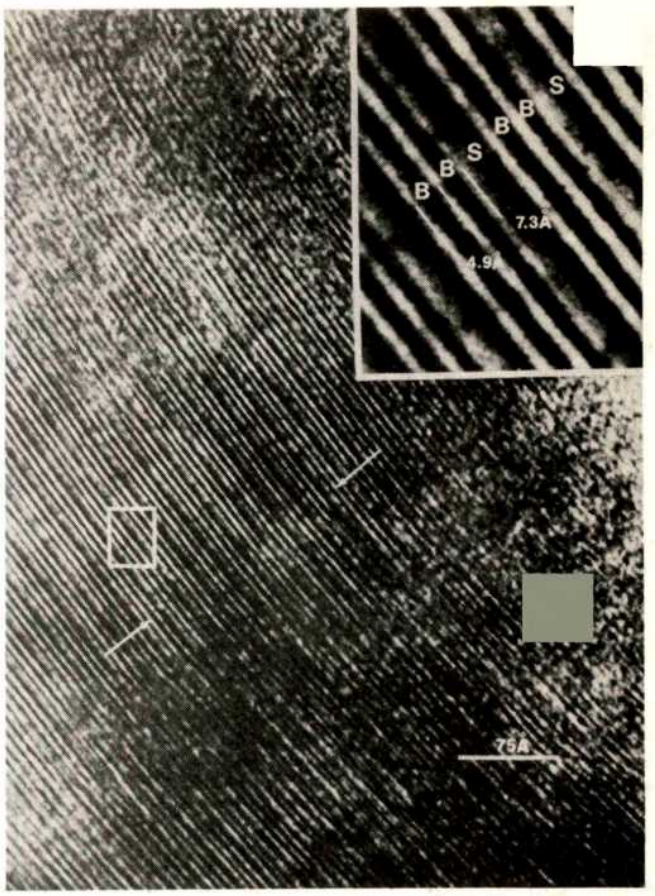

Fig. 2 A HRTEM image of layer silicate ordering in the Murchison matrix. An ordered sequence of 10 SBB units is indicated between the arrows. The inset is an enlargement of the sequence shown in the white rectangle.

The matrix material in Murchison consists of amorphous material[17], and crystalline regions ranging in width from a few thousand to less than one hundred Ångströms. Discrete crystals occur surrounded by amorphous material; crystalline material also occurs as intergrowths in sub-parallel orientations, or as apparently aggregated, but randomly orientated groups of crystals. A considerable fraction (~50%) of the crystalline phases are phyllosilicates.

The extremely small grain size and character of the matrix crystals have also been confirmed by selected area microdiffraction using high-resolution scanning transmission electron microscopy (STEM). (Using a 20-μm limiting aperture in a STEM (Vacuum Generators HB5) equipped with a field-ion emission gun, the effective beam size is 10 Å. Selected area microdiffraction patterns of many phyllosilicate orientations were obtained with beam movement of <100 Å across the Murchison matrix.) Interpretation of microdiffraction patterns having periodicities of ~10 Å or greater is uncertain (J. M. Cowley, personal communication), but is sufficient to confirm the observations obtained by HRTEM imaging.

Figure 1 is a HRTEM photograph of part of the Murchison C2 carbonaceous chondrite showing typical phyllosilicate basal fringes in several crystals that are orientated in sub-parallel directions. The inset is a magnified portion of the same area, showing a disordered arrangement of 7.3 and 4.9 Å fringes representing layers of different types. (Fringe spacings are measured with a relative error of ~10%.) Fringe spacings of ~10 Å have also been observed in other portions of the Murchison matrix[12].

0028–0836/79/290219—02 $01.00

© Macmillan Journals Ltd 1979

Basal fringe spacings of 7.3 Å are typical of minerals from the serpentine group. This group contains minerals ranging in composition from the pure Mg rich end member, serpentine, to the Fe, Mg, Al-silicates of the septechlorite series[11]. Here we refer to the 7.3 Å fringes as representing serpentine layers in order to imply a structural type, rather than a compositional variety. The sheet hydroxides brucite, $Mg(OH)_2$, and gibbsite, $Al(OH)_3$, have basal spacings of 4.9 Å (ref. 11). However, the low total aluminium content of the Murchison matrix[5] excludes gibbsite as a likely species in these layered intergrowths. Interpretation of the images as resulting from alternating layers of serpentine (S) and brucite (B) is consistent with compositional data[5] and the morphology of phyllosilicates at high resolution[6-10]. Serpentine–brucite associations are also known to occur in terrestrial rocks[13] and are consistent with the optical and X-ray studies of Fuchs *et al.*[5].

As far as we know coherently intergrown serpentine- and brucite-type layers have not been described previously. Our observations of such intergrowths are a consequence of improvements in instrumental resolution and techniques as applied to meteoritic phyllosilicates. Assuming that our interpretation of the phyllosilicate phases is correct, it is possible to define several types of intergrowths. For example, we have observed (1) disordered sequences of S and B (Fig. 1), and (2) ordered sequences of ...SBBSBB... (Fig. 2). The origin and stability ranges, if any, of such new types of intergrowths are yet to be determined. Such information may prove to be genetically significant and potentially can provide information about the origins of carbonaceous chondrite matrices. Future experimental studies could well be directed towards establishing pressure–temperature stability ranges for such mixed layer assemblages.

A remarkable feature of the phases shown in Fig. 2 is the nature and extent of the phyllosilicate ordering. Repeats of serpentine and brucite occur continuously for more than 300 Å (...SBBSBB...). Following the procedures of Veblen and Buseck[14], calculations for ordered SBB sequences in the Murchison matrix indicate that 20 repeating units have a probability of 1.57×10^{-15} of occurring randomly.

Experimental work on the serpentine system[15] provides a limited, but, nevertheless, useful guide to the conditions of phyllosilicate formation in the Murchison matrix. Intimate mixtures of brucite-like and serpentine-like layers and their cylindrical morphology[6,10] suggest that the 7.3 Å fringes arise from a Mg-rich serpentine such as chrysotile. An excess of Mg and relatively low silica activity at the time of matrix formation could possibly promote the growth of brucite layers. Alternatively, moderate silica activity and slightly lower temperatures might encourage the growth of brucite and iron-rich serpentines (septechlorites).

The data of Hemley *et al.*[15] suggest that chrysotile and brucite can exist stably between 250 and 375 °C at 1 kbar water pressure. The effects of Fe and Al in the serpentine system are competitive: Fe reduces the temperature range slightly, while the upper stability limit for serpentine is raised by the presence of Al[13]. Specific compositional data are not yet available for the Murchison serpentine–brucite layers. However, indications of compositional variations from Mg-rich serpentine have been obtained in other C2 carbonaceous chondrites[16] and suggest that Fe and Al occur in the layered intergrowths.

A more pervasive influence on the serpentine–brucite stability range may be pressure. The effect of pressure on serpentine stability is not well known. However, at the pressures assumed for the presolar nebula (10^{-2}–10^{-3} atmospheres[5]), the chrysotile–brucite stability field would occur at considerably lower temperatures. Thus, 250–375 °C is a probable upper temperature limit for some of the phyllosilicates in the Murchison matrix.

We thank Drs David Veblen, Tom McKee and Gerry Gibbs for useful discussions. The microscopy was performed at the electron microscope facility in the Centre for Solid State Science at Arizona State University, where John Wheatley and Mary-Lynn Formanack were of assistance. Carleton Moore and the Centre for Meteorite Studies provided the Murchison sample. Financial support was provided by NASA grant NSG 9068.

An experimental measurement of cation diffusion in almandine garnet

COMPOSITIONAL zoning in minerals is a disequilibrium phenomenon which is in principle potentially useful for interpreting the thermal history of the host rock. Almandine-rich garnets from low and medium grade regionally metamorphosed rocks are commonly zoned[1-8]. The manganese content typically varies from core to rim, being high in the centre and low at the rim, producing a bell-shaped profile, whereas Fe is antipathetic to Mn. With the exception of the diffusion models of Anderson and Buckley[9], such zoning has generally been explained in terms of fractionation-depletion processes[2-4] where diffusion in the growing mineral is assumed to be negligible. However, in garnets from high grade rocks[8,10,11], zoning is usually weak, absent or reversed, and recent authors[8,12,13] have favoured the homogenisation of pre-existing or developing zoning by volume diffusion. To evaluate the importance of cation diffusion to garnet zoning, Fe–Mn interdiffusion coefficients have been measured over a restricted temperature range.

Interdiffusion experiments were performed between almandine-rich garnet (100–400 μm in diameter) of approximate composition $(Mg_{0.93}Fe^{2+}_{2.07})Al_2Si_3O_{12}$ and a sinter of $Mn_3Al_2Si_3O_{12}$. Pseudobinary couples comprising garnet and sinter (1:5 weight ratio) were packed in iron crucibles, and sealed in alumina tubes with alumina cement. One atmosphere diffusion runs were performed at temperatures of 822, 915, 934 and 1,002 °C for periods for 300–501 h.

Several garnets of approximately the same size were recovered from each experiment and mounted together for analysis. Only light grinding for a few seconds on 600 grade SiC paper was necessary to reach the centres of the crystals. Provided that the interdiffusion region does not account for more

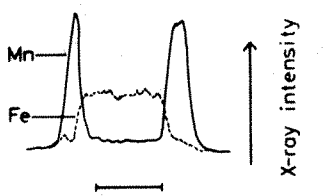

Fig. 1 Fe–Mn interdiffusion in almandine garnet (specimen 117: 915 °C, 501 h) variation of Fe and Mn X-ray intensity along traverse through the centre of a euhedral crystal. Scale bar, 80 μm.

than 20% of the garnet radius (r), the measured diffusion profile will not be significantly distorted if the exposed face is not more than $0.3r$ from the true centre. Samples were polished with diamond paste, coated with carbon, and examined by Cambridge Instruments Geoscan Microprobe.

The interdiffusion regions were analysed with a 'stepping interval' of 2 μm. Operating and data correction procedures are described in detail elsewhere[14]. As it was not possible to identify how close the exposed face was to the crystal centre, errors from misalignment were minimised by selecting only the largest crystals with the smallest interdiffusion regions (always less than $0.3r$). Interdiffusion coefficients ($\tilde{D}$) were calculated by the Boltzmann–Matano method[15], and in common with other systems where only one member of the diffusion couple is available for analysis[16], the Matano interface was assumed to coincide with the crystal rim. The maximum error in $\tilde{D}$ resulting from misalignment is thought to be ±15%, and this has been incorporated in the final uncertainty of the data.

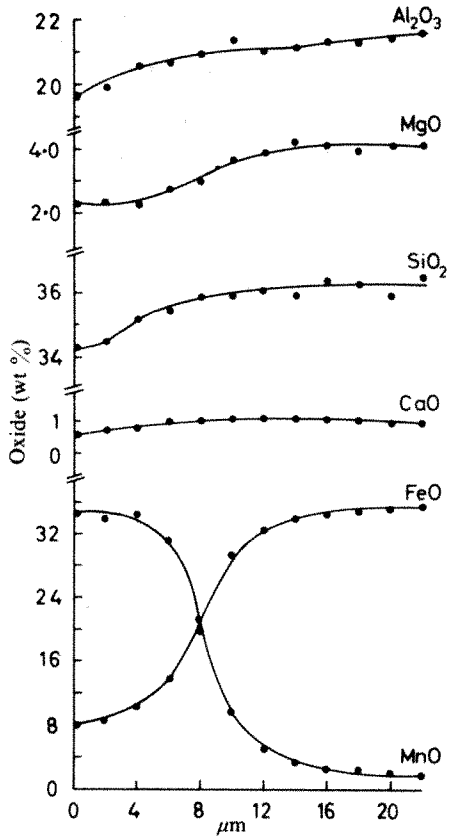

Fig. 2 Typical profiles of Al, Mg, Si, Ca, Fe and Mn in the interdiffusion region of garnet specimen 117 (915 °C, 501 h).

Although the experiments were performed outside the stability field of the garnet, there was no sign of breakdown, or subsequent surface growth. Measurable diffusion profiles were obtained at temperatures above 900 °C. The interdiffusing elements (Fe and Mn) exhibit complementary profiles (Fig. 1) and a detailed analysis is presented in Fig. 2. The shape of the Fe and Mn composition profiles warrants some comment. The flattening of the curves near the interface is probably due to the use of a sinter[16,17] rather than single crystal spessartine. The intersection of the Fe and Mn profiles some 8 μm inside the crystal is of no significance as the cross-over point should not necessarily coincide with either the Matano interface or the original interface[18,19]. It is possible that some interdiffusion of Mn–Mg and Mn–Ca has occurred but the effect on the location of the Matano interface is considered negligible. To a good approximation, the description of the system as an Fe–Mn pseudobinary is valid.

Results for $\tilde{D}$ (Fe–Mn), based on a minimum of eight crystals, are shown in Fig. 3. The composition-dependence of the interdiffusion coefficients may be described by

$$\tilde{D} = D^*_{Mn} \exp(\beta X_{Mn}) \quad (1)$$

where D^*_{Mn} is the tracer diffusion coefficient of Mn in Mn-free garnet, X_{Mn} the content of Mn in wt% (to a maximum of 33.1 wt% for the complete replacement of Fe by Mn) and β the composition factor. Over the temperature range 915–1,002 °C, D^*_{Mn} increased from 3.7×10^{-18} m^2 s^{-1} to 6.6×10^{-18} m^2 s^{-1}, whilst $\beta = 0.09\pm0.01$.

The temperature-dependence of the interdiffusion process may be obtained from an Arrhenius plot of the form

$$\tilde{D}_{Mn} = D_0 \exp(-Q/RT) \quad (2)$$

where $\tilde{D}_{Mn}$ is the interdiffusion coefficient at constant composition, D_0 the pre-exponential factor, and Q the activation energy (in kJ mol^{-1}). Results at 10 and 15 wt% Mn may be described by $\tilde{D}_{10} = 1.07\times10^{-13}\exp[-94(\pm16)\,\text{kJ}/RT]$ m^2 s^{-1}, and $\tilde{D}_{15} = 2.01\times10^{-14}\exp[-72(\pm25)\,\text{kJ}/RT]$ m^2 s^{-1} respectively.

There is good agreement between the present $\tilde{D}$(Fe–Mn) results and data from a recent petrological study. Hensen[20] examined the reaction of garnet (of composition Mg/(Mg+Fe^{2+}) ≃ 0.28) and cordierite at 1,000 °C and 10 kbar, and found that some garnet grains did not homogenise in 305 h. With grains of 10–40 μm diameter, diffusion distances of 5–20 μm would be required to produce uniform compositions. Assuming a diffusion distance, x, of 15(±5) μm, in a time, t, of 305 h, then in this case $\tilde{D}$(Fe–Mg) may be estimated from an approximate solution of the diffusion equations[15]

$$x^2 \simeq KDt \quad (3)$$

where $K \simeq 4$ and is a constant[21]. The calculated interdiffusion coefficient of $5(\pm3)\times10^{-17}$ m^2 s^{-1} compares well with the value of 2.3×10^{-17} m^2 s^{-1} obtained here for $\tilde{D}$(Fe–Mn) at 15 wt% Mn. By defining $\tilde{D}$[Fe–(Mn, Mg)] as the interdiffusion coefficient of Fe with either Mn or Mg, an estimate for this parameter may be obtained by combining the present data for $\tilde{D}$(Fe–Mn) and the result deduced from Hensen for $\tilde{D}$(Fe–Mg). At compositions of ~13 wt% (Mn, Mg) in silicate garnets $\tilde{D}$[Fe–(Mn, Mg)] = $6.77\times10^{-12}\exp[-132(\pm45)\text{kJ}/RT]$ m^2 s^{-1}. Unfortunately, experimental data are available for only a restricted temperature range, and it is dangerous to extrapolate diffusion coefficients to temperatures outside the range of measurement since the diffusion regime and Q may change[22]. A direct assessment of diffusion rates at significantly lower temperatures must await more sophisticated experiments.

Evidence for volume diffusion in natural garnets has recently been cited[8,12,13], but in general, the interpretation of zoning is not easy. In a survey of garnets from west central Massachusetts, Tracy, Robinson and Thompson[7] found they were unable to distinguish fully between garnet zoning due to continuous prograde, or retrograde reactions, or exchange with Fe–Mn–Mg inclusions, or diffusion within the garnet. Other authors[8,12] have suggested that all garnets develop zoning by a fractionation-depletion process during growth, which is subsequently homogenised by diffusion, particularly in the highest grades. From

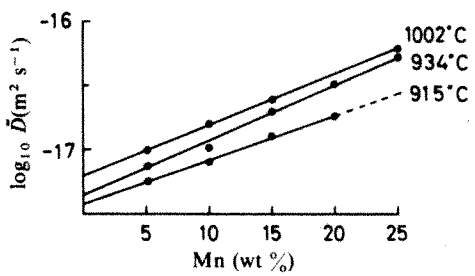

Fig. 3 Composition-dependence of $\tilde{D}$ (Fe–Mn) in almandine garnet at one atmosphere for the temperature range 915–1,002 °C.

estimates of apparent diffusion distances (x), and temperatures of the metamorphic zones, Yardley[8] calculated Q for diffusion in garnet to be 293–418 kJ mol^{-1}. In principle this is a reasonable approach but x may be hard to assess. In the highest grades, homogenised garnets may unequivocally be attributed to volume diffusion if the earlier zoning is recorded, for example, in the composition of inclusions[12]. However, in the lower grade rocks effective diffusion distances may be ambiguous since garnets from a single sample often exhibit a range of zoning profiles[13,23]. It is possible, therefore, that Yardley underestimated x for his samples 146 and 149, and by using plausible alternatives, activation energies as low as 154 kJ mol^{-1} are obtained.

The present experiments confirm that diffusion does occur in garnets, that $\tilde{D}$[Fe–(Mn, Mg)] is typically 10^{-17} m^2 s^{-1} at temperatures around 950 °C, and activation energies are probably in excess of 100 kJ mol^{-1}. In environments of geological interest interdiffusion rates will be sensitive to (T, P), composition gradients, bulk composition and possibly shearing stress[12], or the presence of a fluid, and thus the detailed thermal history may be difficult to elucidate.

I thank the SRC for financial support and Drs S. C. Elphick, C. M. Graham and R. G. J. Strens for helpful comments.

Palaeo-stress estimates in the Moine Thrust Zone, Eriboll, Scotland

STRESSES in the Earth's crust and mantle are of great interest to geologists and geophysicists, particularly the stresses associated with the formation of major tectonic structures. The measurement of quartz microstructural features reported here indicate the stresses during mylonitisation in the Moine Thrust Zone.

Recent studies[1–5] have demonstrated that deformed and syntectonically recrystallised minerals in tectonites may be used to estimate the palaeo-stresses operative during their last deformation. The technique arises from the observation that in large-strain steady-state dislocation creep or hotworking of materials, a stable microstructure develops at low to moderate strains and subsequently remains approximately constant. Similar observations have been recorded for naturally deformed quartzites[7].

The elements of the microstructure that are stress dependent are the dislocation density ρ, sub-grain size d and the size of the recrystallised grains D. The following dependencies apply for metals[6], ceramics[8] and minerals[9–11]:

$$\sigma = k\mu b\rho^{1/2} \qquad \sigma = \frac{l\mu b}{d} \qquad \sigma = md^{-0.7}$$

where σ is the differential stress, k, l and m are constants, μ the temperature compensated shear modulus and b the magnitude of the Burgers vector. In principle it is possible to make quantitative stress estimates if k, l and m have been determined experimentally for the mineral in question and if care is taken[12]. The approximate values of l and m for quartz can be obtained from the observation[13] that at 900 °C and a stress of ~100 MPa (1 kbar) the sub-grains in a deformed quartzite were approximately 5 μm in diameter and the size of recrystallised grains was 20 μm. Goetze[9] has proposed a value of 3 for k. However, there is the possibility that ρ, d and D may have slight temperature dependencies[12], especially D in the case of minerals[3]. This must be resolved before accurate estimates can be made because there are normally large differences between the temperatures of experimental runs and those of crustal deformation. Temperature effects will lead to an overestimation of stresses and the values quoted below probably represent upper limits.

I have measured the variation in ρ, d and D in two mylonite zones in quartz-rich rocks in the Moine Thrust Zone at Eriboll, in North-West Scotland. The first was a narrow, 10-cm thick mylonite band in the Pipe Rock in the imbricate zone at Ben Heilam. A decreasing strain gradient exists away from the mylonite band with only slightly deformed Pipe Rock at ~25 cm from the mylonite band. The second zone was associated with the upper thrust plane (the Moine Thrust) of the Moine Thrust Zone. This out crops in Alt Odhrsgaraidh. These mylonites gradually grade into the overlying Moine schists (see Soper and Wilkinson[14]). A sequence of specimens was collected from both localities. The first appearance of recrystallised grains around the old quartz grain margins was taken as the outer limit of the deformation producing the mylonites. Some low-strain deformation must exist beyond this limit to have produced the recrystallisation. However, it is probable that sub-grain sizes may not have equilibrated to the applied stress at these low strains and they were not measured.

The grain size was determined from optical micrographs of petrological thin sections. Dislocation density and sub-grain sizes were measured (diameters in the case of equidimensional sub-grains or widths if elongated) from electron micrographs taken from foils prepared from the above thin sections. All electron microscopy was performed in an AE1 EM7 high voltage transmission electron microscope operating at 1,000 kV.

The sub-grain size and the grain size, the mean of at least 100 measurements, in both sequences of specimens decreased into the mylonites and then remained constant. In the Pipe Rock, d decreased from 13.3 to 3.7 μm (see Fig. 1) and D from 24.6 to 14.6 μm. The corresponding decreases in the Moine mylonite zone were; d from 13.6 to 2.6 μm and D from 42.9 to 18.6 μm. Wherever possible, only sub-grains away from grain boundaries were measured because of a likely stress intensification in their vicinity. It was observed, in both mylonites, that the presence of mica led to a dramatic reduction in grain size and consequently grain size analyses were limited to mica-free areas. Unfortunately electron microscopy revealed that such areas, in optical micrographs, often contained small mica-grains. The dislocation densities varied erratically in both groups of samples from 2×10^7 to 1×10^8 intersections cm^{-2} (averaging 5×10^7). This observation supports previous findings that care must be taken when using ρ for palaeostress estimates because of the ease with which it can be reset by small strains after the main deformation. The sub-grains have a greater stability as they are low energy structures containing geometrically necessary dislocations and were the most reliable palaeo-stress indicator in the specimens studied. The presence of mica adversely affected grain size estimates.

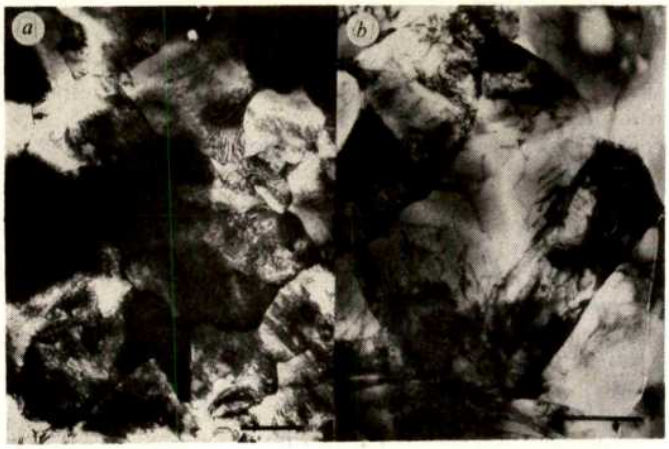

Fig. 1 Electron micrographs showing the decrease in sub-grain size in deformed quartz grains: *a* outside (scale bar, 10 μm); *b* inside (scale bar, 2 μm) a shear zone in the Pipe Rock.

The sub-grain sizes in both areas indicate a stress intensification by a factor between 3 and 4, into the mylonite zones. They indicate a similar low stress, 37 MPa (370 bar) at the edge of each deformation zone. The stresses increase to 128 MPa (1.28 kbar) in the Pipe Rock mylonites and to 180 MPa (1.8 kbar) in the Moine mylonites. The grain sizes indicate a smaller variation, for example, from 50 MPa (500 bar) to 100 MPa (1 kbar) for the Moine mylonites, but as stated previously little reliance can be placed on these values. The average dislocation density indicates a stress of ~35 MPa (350 bar) which is similar to the low stresses indicated by the sub-grains.

Shear zones and thrusts represent zones of inhomogeneous deformation and can be likened to shear band structures in metals, ceramics, polymers and soils[15,16]. These bands mark zones of strain softening which may arise from mechanical or thermal effects. It has been suggested that mylonites also indicate zones of strain softening[17]. In the case of those studied there is no evidence for any marked shear heating and it is concluded that a mechanical softening mechanism was operating. I would expect the mylonite zones to initiate from local stress notches in the same way as shear bands initiate. Notches were not identified but would be expected as the Pipe Rock is inhomogeneous and in the case of the Moine Thrust there are marked changes in rock type. Therefore the propagation of the mylonite zone can be regarded as being similar to that of a shear band or a planar discontinuity in a cohesive material[16]. In such a model, which would apply to narrow zones, the stress gradient recorded by the sub-grains would be that at the tip of the propagating discontinuity. It would cause deformation in the surrounding material with that above and below frozen in after propagation. The softening due to the mylonite zone which develops leads to a relaxation of the localised stress concentration and also concentrates the deformation into the zone. Growth of the zone will occur if the flow rate in the mylonite cannot accommodate the overall imposed regional rate. The stresses required to produce the mylonite during the initiation and during the growth of a shear zone or ductile fault should be similar for a given rock type and deformation temperature. After the development of the required width of mylonite to accommodate the regional strain rate the adjacent country rock should play little further part in the deformation and the above gradients are preserved. Therefore the high stress estimates are likely to be those associated with the mylonite development and the low estimates should approximate to the regional background stresses to which the former relax. I suggest that the difference between the two represents the overall stress variation associated with the formation of the Moine Thrust Zone in the area studied. Note that the dislocation densities indicate a stress close to the relaxed stress. This may indicate that, in this area, the dislocation densities have been reset to the regional stress after the mylonite formation.

In conclusion, I suggest that the quartz mylonites in the Moine Thrust Zone, at Eriboll, were produced by a localised stress of ~150 MPa (shear stress of 75 MPa or 750 bar) with the regional stress being ~35 MPa (shear stress of 17.5 MPa or 175 bar) which is the likely stress during thrusting after the mylonites formed.

I thank Dr R. Sibson and N. Shaw for helpful discussions, NERC and the USGS, Earthquake Hazards Reduction Program, contract 14-08-001-G-377 for funds.

Recent thrusting in the Appalachians

NUMEROUS orogenic episodes from late Precambrian to early Permian have shaped the Appalachian Mountains. Its last orogeny, the Allegheny orogeny, began before the end of the Lower Carboniferous and ended after the early Permian[1]. Most of the Palaeozoic mountain belts of Europe and other continents were worn down long ago. It is still being discussed whether the Appalachians were constantly uplifted in post-Palaeozoic times or whether there was a Cenozoic rejuvenation of uplift[2–4]. The composition of the Mesozoic and Cenozoic Atlantic coastal sediments and their gentle dip away from the Appalachians imply that the mountains stood as a high broad arch despite two hundred millions of years of erosion[1]. Geological evidence has been found and is reported here of thrusting during the past 12 yr at many locations in the Appalachian Plateau and Valley and Ridge province. Five sites have been selected in Tennessee, West Virginia, and Pennsylvania to show considerable horizontal shortening and associated vertical uplift that actually holds up the mountain ranges. The recent faulting and folding have been quantitatively studied and absolutely dated by offsets of boreholes that have been drilled for blasting operations in road-cuts.

Along the interstate highway 40 between Harriman and Rockwood, Tennessee folded and thrusted Pennsylvanian shales and sandstones are exposed striking N 45° E and dipping 10° towards south-east or north-west (Fig. 1). In this position the highway trends west-north-west and cuts across a syncline more than 15 km wide in the transition zone between the Valley and Ridge province and the Cumberland plateau following to the west.

West (10.5 km) of exit 338 (Westel road) on interstate highway 40 east, a thrust fault of supposedly Alleghenian age has recently been reactivated by an offset of 25 cm horizontal throw and 16 cm vertical movement (Fig. 2). The thrust plane strikes and dips N 42° E/32° SE and the hanging wall block is overthrusted in the direction of N 80° W, being parallel to the

orientation of the road-cut walls as can be seen by the displacements of the boreholes. Likewise, the direction of maximum horizontal stress that caused the thrusting seems to be N 80 °W-orientated as no strain–slip of the rocks towards the open road-cut during the past 12 yr could be observed. The boreholes were drilled in summer 1966. The same thrust throw was manifested in April 1974 as in August 1978. Thus, for the period 1966–74 an annual average thrust-slip rate of 3.8 cm can be calculated. From 1974 to 1978 no distinct offset could be observed.

Four kilometres east of exit 338 on highway 40 east, boreholes were drilled during the summer of 1968. Here, on the eastern flank of the aforementioned syncline, Pennsylvanian sandstones and shales strike and dip N 70° E/20° NW (Fig. 3). Highway 40 now is N 40° W-orientated and the displacements of the drill-holes at both sides of the road indicate thrust faulting along bedding planes, particularly at the transition from sandstones to shales. The direction of thrusting, however, is no longer strictly parallel to the road-cut walls. The boreholes are obliquely offset to the road on both sides of the highway revealing an east to E 40° S thrust direction of the hanging wall layers. The maximum horizontal throw recorded is 20 cm and the corresponding vertical movement is 7.5 cm. Some drill-holes are offset twice along different thrust (bedding) planes.

Considering the two exposures west and east of exit 338 on interstate highway 40 it is concluded that a recent stress field with a maximum compressive stress directed west-north-west has horizontally shortened an area of 14.5 km length by at least 45 cm and has induced vertical uplift of 7.5 cm to 16 cm during the past 12 or 10 yr, respectively (Fig. 4).

West (16 km) of Franklin, West Virginia and 3 km south-west of Oak Flat, West Virginia dark siltstones and shales of presumably middle Devonian age are exposed along highway 33 (Fig. 1). The sediments strike and dip N 50° E/15° SE. Boreholes were drilled there for blasting operations between June and August 1973. Five years later the total horizontal displacements of the drill-holes along two bedding planes was about 50 cm. The hanging wall sediments were shifted to W 15° S. As the direction of overthrusting almost corresponds with the strike of sediments no vertical uplift occurred. This considerable offset during such a short time-span seems to require other means for displacement in addition to tectonic stress. But the direction of thrusting is again parallel to the road-cut, although the inclination of the sediments towards the highway could have induced gravitational sliding at the north-western road-cut wall. A west-south-west-directed maximum horizontal stress has been suggested as the cause of the recent displacement of the boreholes whose major throw may have occurred shortly after the blasting. A major strain release by thrust-slip movements (soon after the blasting), is also indicated by the observations at site 1 (Fig. 1, Table 1).

Exposures of Devonian quartzites have been studied on highway 22, 14.5 km north-west of Millerstown, Pennsylvania. The layers are almost horizontal (N 8° E/5° SE) being close to the centre of a syncline within the Pennsylvanian Valley and Ridge province. According to borehole offsets only a minor thrusting in the direction of N 80° W has been observed. The horizontal throw amounts to 1.5 cm and vertical movements were calculated to be 0.1 cm. I do not know when the drilling and blasting for the construction of the road-cut occurred, but according to the state of the highway and the freshness of the exposed rocks along the road sides it seems that blasting was conducted no more than 10 yr ago.

The highway 22 continues northwestwards and intersects narrow folds of the eastern Allegheny plateau. About 6 km north-west of Port Matilda, Pennsylvania the highway 22/322 cuts across Mississippian and Pennsylvanian red beds of sandstones, siltstones and shales that strike and dip N60° E/20° NW. Many displacements of drill-holes indicate overthrusting along bedding planes in the direction of E 50° S. There are numerous displacements of minor throw within the sandstone sequences and there are a few thrusts of major throw along the sandstone/shale contact planes, where friction is reduced. Thus, the maximum thrusting with a horizontal throw of 14 cm and a vertical uplift of 5 cm has been measured of a sandstone overriding a shale. Another thrust-fault was recorded with a horizontal throw of 5 cm and a vertical uplift of 1.8 cm. Along both sides of the highway 322, from 6 to 8 km north-west of Port Matilda, Pennsylvania, most of the 20°-NW-dipping thrust-faults indicate a movement of the hanging wall blocks in the direction of E 50° S. But some borehole offsets at the south-west

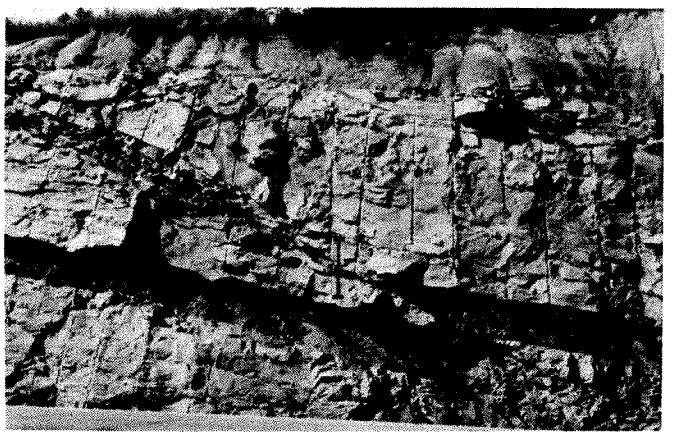

Fig. 2 Thrust-fault in Pennsylvanian sandstones intercalated by a dark shale layer, located between Rockwood and Harriman, Tennessee, 10.5 km west of exit 338 on interstate highway 40 east. Borehole offsets occurred after blasting in 1966. Displacements of 25 cm horizontal throw and 16 cm vertical uplift have been recorded in 1974. Direction of thrust motion is N 80° W and corresponds to the orientation of maximum horizontal stress. Scale bar, 1.83 m (6 ft).

Table 1 Sites of recent thrusting in the Appalachian Plateau and Valley and Ridge province

Location	Direction of thrusting and inferred direction of σH_{max}	Inclination of thrust plane	Horizontal throw	Vertical throw	Period of recent thrusting
1*. Rockwood–Harriman, Tennessee Interstate 40 east, 10.5 km west exit 338	N 80° W	32° SE	25 cm	16 cm	1966–74
2*. Rockwood–Harriman, Tennessee interstate 40 east, 4 km east exit 338	East to E 40° S	20° NW	20 cm	7.5 cm	1968–78
3*. 3 km south-west Oak Flat, West Virginia, highway 33	W 15° S	0°	50 cm		1973–78
4*. 14.5 km north-west Millerstown, Pennsylvania, highway 22	N 80° W	5° SE	1,5 cm	0.1 cm	about 10 yr
5*. 6–8 km north-west Port Matilda, Pennsylvania highway 322	E 50° S N70° E	20° NW	14 cm 5 cm	5 cm 1.8 cm	about 10 yr

* Numbers correspond to sites in Fig. 1.

road side wall show strain–slip movements in direction of N 70° E towards the open road-cut. A recent maximum horizontal compressive stress which caused the thrusting is suggested to be north-west directed rather than west-north-west, as can be deduced from the strain–slip movements.

The drill-hole offsets were considered to have been caused mainly by blasting, as at site 1 where measurements have been repeated no displacement was observed during the past four years. However, there is evidence of updip thrusting after the blast operations and not of gravity controlled movements. The thrusting at sites 1 and 2 occurred in exactly the opposite directions due to the corresponding orientation of maximum horizontal stress (σH_{max}) at both locations. The change in the orientation of the road-cut at site 2 (N 40° W) in respect to the direction of the road excavation at site 1 (N 80° W) is not reflected by the orientation of the borehole displacements.

The energy released by the explosions is probably insufficient to displace rock masses of more than 50,000 m^3 (site 5) updip on planes as one block.

Borehole offsets have been observed in southeastern Connecticut after blasting operations in 1970 [5]. Measurements at one location have been repeated between 1970 and 1978 revealing that the initial displacement of 23 mm was followed by a period of creep at an average rate of 2.8 mm yr^{-1}. It is suggested that this permanent creep results from stresses acting on the Appalachians at present, rather than from palaeo-stresses that would have created one episodic rock movement during or shortly after the blasting. As for site 1 it is suggested that thrusting will continue if σH_{max} reaches the critical value that was achieved some time between the blasting of 1966 and 1974.

If the borehole offsets on highway 322 between Port Matilda and Philipsburg, Pennsylvania and those on highway 22 between Lewistown and Millerstown, Pennsylvania are about 10 years old, we may apply the calculated amounts of annual uplift from the sites where recent thrusting has been studied to the Pennsylvanian Valley and Ridge province in general. Vertical movements of at least 2 cm yr^{-1} can be inferred from the structural investigations on the highway 322 north-west of Port Matilda, Pennsylvania and of 0.1 cm on the highway 22 west-north-west of Millerstown, Pennsylvania. However, it has been frequently observed that recent thrusting is enhanced in 20°–30° inclined sediments and that thrusting decreases in more gentle or steeper dipping layers.

The crests of the main ridges of the Valley and Ridge province north-west of Harrisburg, Pennsylvania show small remnants of an old peneplain surface formed by an ancient Susquehanna river-system when the region was near base level. The Susquehanna river is now superimposed on the rejuvenated Valley and Ridge province that was regionally uplifted by about 300 m in relation to the present valley floor. If a continuous uplift of 2 cm yr^{-1} is inferred for the recent and past vertical movements in that area, the present elevation of the ridge crests above the ancient peneplain will be achieved during a period of 15,000 yr only. However, at this point of investigations of recent thrusting and folding in the Appalachians we have to consider the thrust–slip rates as local phenomena.

Fig. 3 Recent thrusting after drilling and blasting of boreholes in 1968 occurred along a bedding plane of Pennsylvanian sandstones, 4 km east of exit 338 on interstate highway 40 in eastern Tennessee. Scale bar, 1.83 m (6 ft).

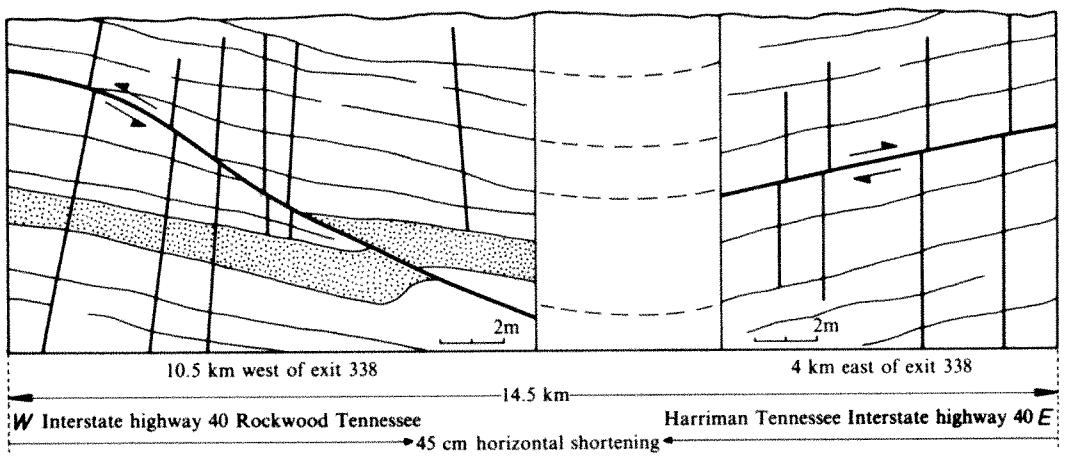

Fig. 4 Recent thrusting and folding of a syncline in Pennsylvanian sandstones and shales (stippled), between Rockwood, Tennessee and Harriman, Tennessee. More or less vertical lines indicate boreholes that are offset at a recently reactivated thrust-fault (left) and along a bedding plane (right).

The rates of relative vertical movements as determined from levelling data of the eastern US reveal that the Appalachians rise relative to the interior platform and to the Atlantic coast at rates of up to 0.6 cm yr^{-1} (ref. 6). This is already two orders of magnitude larger than the estimated average uplift from the early Cretaceous to the present. Brown and Oliver[6] have published relevelling profiles with small peaks of increased vertical motion superimposed on the broader uplift of the Appalachians. Two of their profiles traverse close by the sites where recent thrusting was recorded. A peak of prominent uplift at Tyrone, Pennsylvania is located 22 km south of the Port Matilda, Pennsylvania site. Another, but less pronounced peak of vertical motion between Somerset, Kentucky and Harriman, Tennessee is established about 100 km north of the Rockwood–Harriman, Tennessee site in the continuation of the geological strike.

An apparent uplift at the Blue Ridge–Piedmont boundary relative to the Atlantic coastal plain and the Valley and Ridge province is indicated by precise relevelling along a line from Morristown, Tennessee to Newton, North Carolina and along another traverse in Georgia[7].

The areas of investigation and generally the central and southern Appalachians are associated with only a moderate seismicity[8]. Nevertheless, the Appalachian mountain belt is contoured by a cluster of epicentres in relation to its foreland and hinterland. The Atlantic coast area is seismically active only in Virginia and South Carolina, the latter area being part of the Charleston–Cumberland seismic zone as an onshore extension of the Atlantic Blake transform fault[9]. The Rockwood–Harriman, Tennessee site of recent thrusting in eastern Tennessee is located at the north-western termination of the Charleston–Cumberland seismic zone. There, the present maximum horizontal north-west–south-east compression (σH_{max}) inferred from thrusting does not correspond to the north-east–south-west-orientation of $\sigma 1$ derived from composite fault plane solutions of earthquakes that occurred in the same seismic zone further to the south-east at Lake Jocassee, South Carolina[10] (the seismic data have been revised since instrument polarities were reversed).

The results of structural investigations in the Rockwood–Harriman, Tennessee area contrast also to the *in situ* stress directions of a north-east σH_{max} and a north-west σH_{min} obtained from hydrofracturing[11]. Other σH_{max} directions determined from hydrofracturing in the western Appalachians from West Virginia to New York State approximately correspond to those derived from recent thrusting at the West Virginia and Pennsylvania sites. Both areas are associated with little seismicity despite prominent recent tectonic events. Some horizontal *in situ* stresses have been determined in the Appalachian Piedmont from Georgia to Pennsylvania by the overcoring technique[12]. All sites but one reveal σH_{max} to be north-east directed. The Appalachians are probably governed by two different stress regimes, one in the west with σH_{max} orientated north-west to east-west and another in the eastern Appalachians with σH_{max} predominantly north–east directed. It is assumed that absolute stresses of 50–150 bar as determined by *in situ* overcoring in the Piedmont may be enough to cause recent thrusting like that in the Appalachian Plateau or Valley and Ridge province.

I thank the Departments of Highways at Nashville, Tennessee, Knoxville, Tennessee, and Charleston, West Virginia for dates of the drill periods.

Direct measurements of secondary currents at a river inflexion point

SECONDARY currents are defined as currents which occur in a plane normal to the local axis of primary flow. They may develop in pipes or open channels as a result of non-equal distribution of boundary shear stress or by skewing of cross-stream vorticity into a long stream direction[1–3]. Secondary currents distort the distributions of primary isovels and boundary shear stress from those found in simple flows and have important effects on sedimentary processes of erosion and deposition[4,5]. Direct measurements of secondary currents in river bends were reported recently[6]. Further data have been obtained for the reach around the inflexion point between bends (Fig. 1) and are reported here.

At a river bend a strong skew-induced secondary flow cell carries surface water towards the outer bank and bed water towards the inner bank. Measurements made in rivers indicate that a small cell of reverse rotation can exist close to the outer bank in a bend, if that bank is steep[6].

This cell is generated locally by interaction between the skew-induced cell and the outer bank[6,7]. It is not connected with the reverse circulation of a relic cell from an upstream bend[8–10]. Few measurements have been made in the reach between opposite bends, however, to ascertain how the secondary current pattern from the upstream bend decays, to be replaced by that associated with the downstream bend. Some observations have been made in laboratory flumes[8–10]. Flume data collected by Toebes and Sooky[10] suggest that the skew-induced cell for the downstream bend tends to displace the relic cell laterally towards the outer bank in the downstream bend. Wilson hypothesised that this might be the case on theoretical grounds[11]. In the flume study the decaying cell does not ever disappear completely, so that a remnant cell persists through the downstream bend.

The secondary flow pattern at the inflexion point shows two approximately symmetrical cells which converge at the surface and diverge at the bed. Chacinski and Francis observed a rather different system in their flume study[8,9]. Here the skew-induced cell for the second bend originates near the bed and develops upwards, displacing the decaying cell as it does so. This leads to a

system of two stacked cells in the second bend, the upper cell being a remnant of the upstream flow.

The explanation of these apparently contradictory results probably lies in the cross-sectional shape of the flume channels used in the two experiments. In Toebes and Sooky's case the width to depth, or aspect ratio was about 1.5. However, Chancinski and Francis used much higher aspect ratios up to 40 and in some cases 80. As the latter values are more typical of the aspect ratios found in natural streams, it should be expected that the observations of Chacinski and Francis should be more directly applicable to rivers.

Rozovskii[12] used the equations of motion to produce equations describing the development and decay of skew-induced secondary flow. On the basis of these equations, he suggests patterns like those observed by Chacinski and Francis for connecting bends of different directions[12].

To investigate the pattern of secondary flow between bends in a river, data were collected at Penstrowed, Powys, on the River Severn, using an electromagnetic flow meter. This instrument measures velocity in two perpendicular directions simultaneously with an accuracy of $10\,mm\,s^{-1}$ (refs 13–15). Measurements were made at three sections across the river between two meander bends. The meter was positioned to measure long and cross-stream velocity. These are not necessarily the primary and secondary velocities but a theory previously developed allows us to calcaulate these components[6]. Although the measurements were made on three consecutive days discharge was not constant. However, the change in discharge did not produce a marked change in the geometry of flow through the reach and so it is still possible to compare qualitatively the patterns of flow at the three sections. Section 1 was located at the exit of the upstream bend, section 2 at the inflexion point, and section 3 at the entrance to the downstream bend (Fig. 1).

The secondary flow pattern at the bend exit (Fig. 2) is dominated by the skew-induced cell from the upstream bend. There seems to be a rather weak outer bank cell near the right hand bank. This is not surprising as secondary currents are known to persist for considerable distances downstream from single bends[16]. The data for section 3 (Fig. 3) at the entrance to the downstream bend indicate that this is not the case for a series of bends. Here a skew-induced cell of opposite rotation to that in the upstream bend dominates the secondary flow pattern. Section 2 (Fig. 4) at the inflexion point, seems to show a two cell system with vertical stacking in the central part of the channel. The upper cell is the relic skew-induced cell from the upstream bend, whilst the lower cell is the developing skew-induced cell for the downstream bend. The right-hand margin of the system is complex, but there seem to be outer bank cells resulting from interaction of the skew-induced cells with the bank[6].

The river measurements are similar to those made by Chacinski and Francis in a laboratory flume of high width-to-depth ratio. A significant difference is that the skew-induced circulation for the downstream bend in the River Severn was fully developed at the bend entrance, whilst in the flume experiments a remnant of the upstream circulation persisted well into the downstream bend. The reason for this difference may lie in the difference in bed topography between the river and the flume. In the river the cross-section at a bend is highly asymmetrical with the deepest point close to the outer bank. At the inflexion point the channel is almost symmetrical, often with a pronounced medial bar. The switching of thalweg from right to left banks between sections 1 and 3 reflects this. It is the curving of streamlines resulting from this effect of bed topography which is initially responsible for the generation of the new skew-induced cell close to the bed. At the bend entrance downstream, plan form curvature reinforces this effect, leading to full development of the skew-induced secondary flow early in the bend. Clearly this would not be the case in the laboratory experiments carried out in flume channels with uniform rectangular cross-sections[8–10]. In a channel with a uniform cross-section, plan shape curvature alone is responsible for generating the new skew-induced cell and consequently that cell does not fully displace the relic cell until well into the downstream bend.

Direct measurements of secondary currents at a river inflexion point confirm that the system of cell development proposed by Chacinski and Francis can operate in rivers as well as uniform flume channels. An important difference is that the bed topography in a natural stream seems to result in early and more complete replacement of remnant cells from an upstream bend.

We thank Professor Peter Bradshaw for helpful criticisms.

Aneuploidy in mouse fetuses after paternal exposure to X rays

ANEUPLOIDY can result either from non-disjunction, giving trisomy and monosomy, or from chromosome damage leading to loss of chromosomes (monosomy) only. It is known that chromosome loss can be induced after irradiating post-meiotic male germ cells[1], but apart from findings on radiation-induced non-disjunction in oocytes from mice[2–5], there is no evidence that paternal exposure to X rays induces chromosomal mal-segregation during male meiosis to produce monosomic and trisomic offspring. Szemere and Chandley[6] did observe significantly more mal-segregated X and Y chromosomes in spermatocytes II after 100 and 200 rad had been given during preleptotene and pachytene, but failed to recover aneuploid fetuses in progeny from irradiated males. They suggested that only a few aneuploid spermatocytes would be transmitted to the next generation. We have now shown that such induced aneuploidy is indeed transmitted and can be detected in a monosomic and trisomic condition in F_1 fetuses on day 9.5 of gestation.

Twenty 8–10-wk-old random-bred NMRI/Han male mice were given whole-body irradiation of 20 or 200 rad (10 males in each group) and were mated from day 2 to day 36 after irradiation to untreated females of the same age and strain. Non-irradiated males served as matched controls. The radiation source was a Philips–Müller tube with tungsten anode and beryllium window; tube voltage was 150 kV and current 8 mA, Cu filter was 1 mm and the exposure rate was 55 rad min^{-1}. The animals were housed under controlled conditions, darkness lasting from 6 pm to 6 am, tapwater and Altromin pellets (RH 1324) were supplied *ad libitum*. The females were checked every morning (day 0.5) for vaginal plugs and those found to be positive were isolated and kept separately until day 9.5 *post coitum*.

The pregnant females were killed by cervical dislocation, their implantation sites removed and placed into TC 199 culture

medium containing 17% fetal calf serum, L-glutamine 2 μM, penicillin 1,000 IU ml^{-1}, streptomycin 10 mg ml^{-1} (reagents from Seromed) and 0.004% colchicine. The embryo proper or the egg membranes only were cultured for 2 h and prepared cytologically according to the method of Evans *et al.*[7]. Chromosomes from at least 7-d-old air-dried slides were stained for G-banding and metaphases were analysed from coded slides. Only one karyotype was prepared from the best 'banded' metaphase with optimal spreading of chromosomes from each embryo or egg membrane. As many extra karyotypes as possible, however, were compared when the first metaphase was abnormal. This procedure of analysis certainly detects those anomalies present in all cells, but would miss some aneuploidies developing only in a mosaic condition.

It has been suggested[6] that triploid mouse fetuses might arise from irradiation of early spermatocytes. We observed four such fetuses with a karyotype of 60,XXY—three in one litter after 200 rad and one fetus after 20 rad. All triploids were generated, however, from fathers exposed 10 days before mating—after the second meiotic division. This finding, together with the fact that three triploids were derived from one litter and the observation of a high spontaneous background of digynic triploidy in the NMRI/Han mouse strain[8], suggested that X-ray exposure did not enhance polyploidy in our study.

Overall, 10 of 601 fetuses derived from irradiated fathers were monosomic or trisomic, but no aneuploidy was found among 211 karyotyped fetuses from non-irradiated fathers (Table 1). All the aneuploid fetuses were generated from different fathers and mothers. Our data from the untreated fetuses confirm that aneuploidy is rare in post-implantation mouse embryos not exposed to mutagens.

The identification of the odd chromosome in all 10 aneuploid fetuses provides further information on the survival of monosomics and trisomics during mouse embryogenesis, although chromosomal mosaicism cannot be excluded in our fetuses and in those of other studies[9]. The results shown below are in agreement with the conclusion reached after the studies of robertsonian translocations in the tobacco mouse[9]—that autosomal monosomics are more prone than trisomics to an early elimination during pre-and peri-implantation development.

The following aneuploidies were identified, with the day of mating after irradiation given in parentheses: First group after 20 rad with 41,XX, +11 (21); 41,XY, +2 (21) and 41,XX, +11 (31). Second group after 200 rad with 39,X0 (4); 39,XY, −8 (5); 41,XX, +14 (7); 41,XY, +13 (16); 39,X0 (25); 41,XYY (28); 40,X0, +13 (32). The latter karyotype with 40,X0, +13 is obviously the result of two events: (1) a sex-chromosome loss either by non-disjunction or due to loss after breakage, and (2) due to non-disjunction of chromosome 13. No 41,XXY karyotype was found in our study, in agreement with the observation of only one XXY male among more than 5,000 offspring studied genetically after paternal irradiation[1].

Non-disjunction was induced in mouse oocytes after exposure to equally low doses (10–30 rad) during the preovulatory phase[2,3]. Aneuploidy was assessed in these studies in oocytes, that is, at a stage long before selection against chromosomally imbalanced fetuses could act. Our observation of 1.4% aneuploid fetuses 9.5 days *post coitum* after paternal exposure to 20 rad would mean that mouse spermatogenesis is at least as sensitive to radiation-induced non-disjunction as oogenesis. Aneuploidy was not significantly enhanced over the effect after 20 rad with the still higher dose of 200 rad. Either some kind of saturation was already reached at the cellular targets for non-disjunction, or the enhanced effects after 200 rad were modified secondarily by, for example, the elimination during spermatogenesis or embryogenesis. [Note that we did not observe any structural anomaly in the 9.5-d-old fetuses after 20 rad, but found balanced and imbalanced translocations after exposure to 200 rad.]

In 6 of the 10 observed aneuploid fetuses the mal-segregation can be allocated with certainty to meiosis I or II. Both primary and secondary non-disjunction were also found to be involved in generating some cases of Down's syndrome[10,11]. The other four fetuses, however, were derived from sperm irradiated in the vas deferens (39,X0 and 39,XY, −8) or the epididymis (41,XX, +14), or irradiated as mid-spermatids (41,XY, +13). A chromosome loss most probably may explain the X0 karyotype and the monosomy 8, although mitotic non-disjunction during early cleavage cannot be ruled out and should have produced a mosaic condition. This suggestion is not unlikely, because some fetuses with mosaic aneuploidy were found after maternal and paternal irradiation[5,6]. Mitotic non-disjunction during early cleavages could also explain our two trisomic fetuses (trisomy 13 and 14), generated 7 and 16 d after irradiation. Either we failed to detect the respective monosomic cell lines, or these hypodiploid cells were selectively eliminated earlier—a reasonable suggestion, as monosomics are usually eliminated during the early mouse embryogenesis[9].

A study of human spontaneous abortions showed that occupational X-ray exposure in man can increase the risk of chromosomally abnormal conceptions[12]. Our finding of fetal aneuploidy after paternal irradiation, affecting both autosomes and sex chromosomes, even after exposure to rather low doses, may have implications for the human situation and may lead to a better understanding of the mechanisms involved in non-disjunction.

We thank Mrs H. Schulz, Mrs S. Gebauer and Mr S. Jackson for technical assistance, Mrs B. Schäfer-Berner for photographic work, Dr T. Grimm for advice on the statistical evaluation and Dr P. Virsik for advice on dosimetry. The study was sponsored by a grant of the European Commission 206-76-7 BIO D. Radiation facilities were provided by the Institut für Medizinische Physik und Biophysik (Professor Harder).

Vitamin D and its analogues as a new class of plant growth substances affecting rhizogenesis

SEVERAL substances actively promote adventitious root formation in cuttings: they include indoleacetic acid (IAA), indolebutyric acid (IBA) and α-naphthylacetic acid. Others, which themselves do not or only slightly promote root formation, can act synergistically with one or another of the former to enhance their activity[1]. Root formation in cuttings is exploited in the propagation of new varieties of plants, such as polyploids or those with disease resistance. While screening steroids for their effect on rooting in *Populus* spp., we have found a synergistic effect of cortisol on IBA-promoted root initiation[2]. We now report a similar effect of vitamin D and its analogues, and suggest an endogenous function for this group of compounds.

Vitamin D_2 and vitamin D_3 are produced by UV irradiation of the respective provitamins ergosterol and 7-dehydrocholesterol—transformations which can be effected *in vitro* or *in vivo* in animal tissue. The thermal and photochemical pathway involves the sequence: ergosterol, previtamin D_2 and vitamin D_2. Tachysterol and lumisterol, once thought to be intermediates, are now considered to be isomerisation side products[3] (Fig. 1).

To test for their effects on plant growth, ergosterol, dihydrotachysterol and vitamin D_2 were applied alone and in the presence of IBA, to *Populus tremula* (aspen) herbaceous cuttings. Dihydrotachysterol, a reduction product of tachysterol, was used because the latter is not readily available and is highly susceptible to aerial oxidation. Later work (results not given) has shown that dihydrotachysterol and tachysterol have similar activities.

The results (Fig. 2*a*) show that ergosterol alone has no significant effect at concentrations of 10–50 mg l^{-1} but that with dihydrotachysterol or vitamin D_2 alone, the number of adventitious roots produced increases by about 60% and 100%, respectively, the maximum effect occurring at 10 mg l^{-1}. IBA alone at 10 mg l^{-1} promoted rooting as expected, by about 200% (Fig. 2*b*). Ergosterol in the same concentration range of 10–50 mg l^{-1}, applied with IBA at 10 mg l^{-1}, caused no greater root formation than did the IBA alone, whereas the same concentration range of dihydrotachysterol and vitamin D_2 applied with IBA at 10 mg l^{-1}, caused a pronounced increase in root formation. Thus, in the concentration range 10–50 mg l^{-1} there was a significant enhancement of root formation (compare this with the similar, but less pronounced, synergistic effect obtained with cortisol and IBA in comparable conditions[2]) and this effect was dependent on concentration. A similar enhancement of root formation has also been observed with woody cuttings from *Populus tremula* and *Populus nigra* and with cuttings of varieties of *Phaseolus vulgaris*.

Vitamin D_3 has been isolated from *Dactylis glomerata* and various species of grasses[4] and the presence of vitamin D or its analogues has been suspected in other plant tissues said to have anti-rachitic activity[5]. However, so far no function has been proposed for them in plants. Using the same rooting test, we have found that vitamin D_2 and vitamin D_3 have similar activities (results not shown). Concerning structure/effect relation-

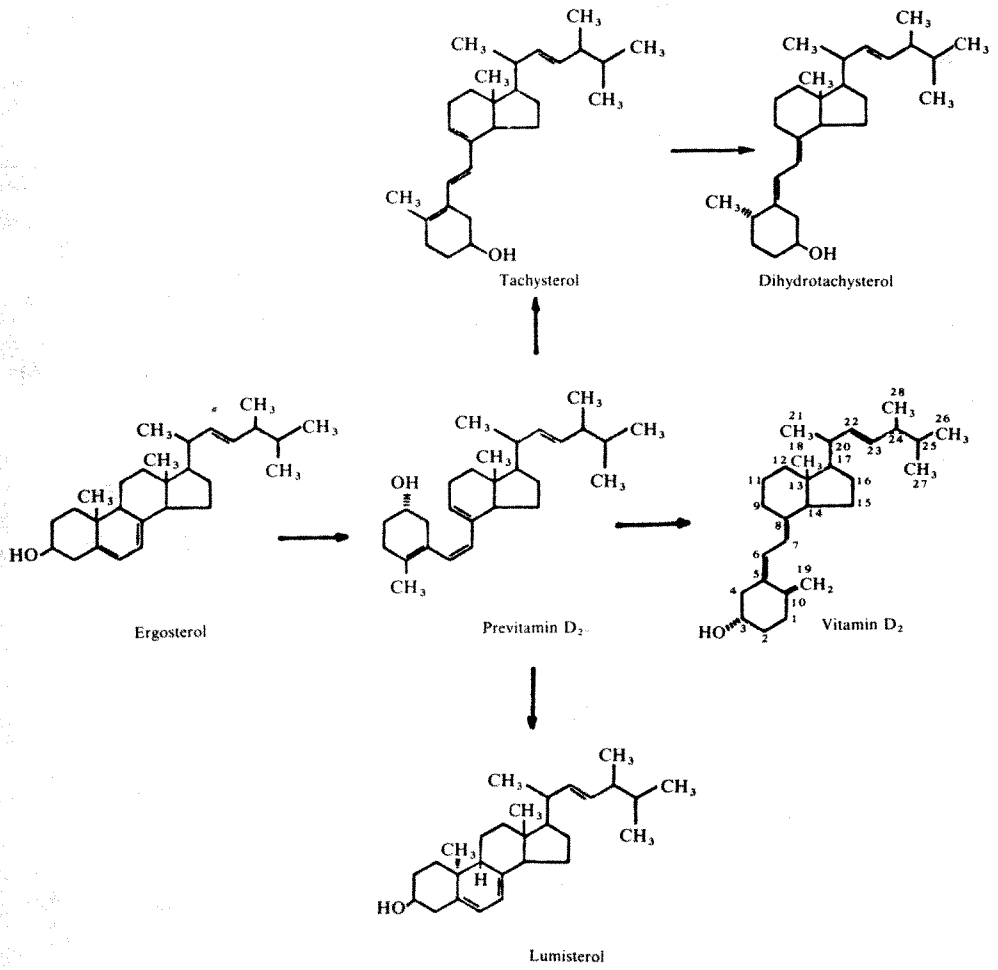

Fig. 1 Thermal and photochemical transformations of ergosterol.

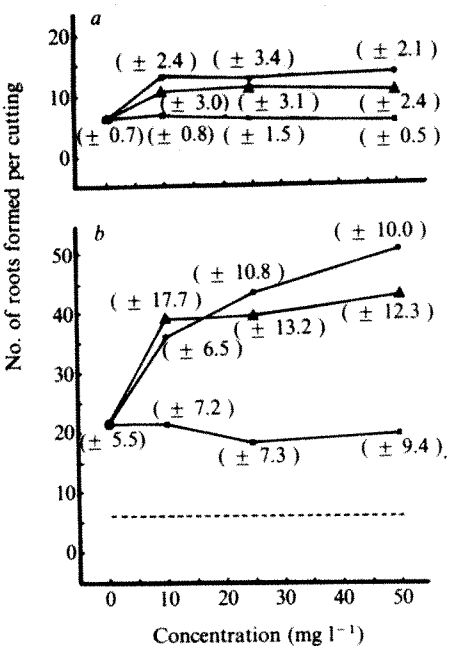

Fig. 2 The *Populus tremula* seedlings were prepared as previously described[2] and solutions of the test substances were applied to the cuttings for 24 h followed by a change to distilled water. The adventitious roots were counted after 18 d of culture, by which time the number of roots formed was essentially constant, and the results expressed as the mean of at least four culture series (s.d. in parentheses). *a*, Without IBA; *b*, with 10 mg l^{-1} IBA. ●, Vitamin D_2; ▲, dihydrotachysterol; ×, ergosterol; – – –, H_2O control.

ships, we can say that the opening of the steroid ring B of ergosterol to give a seco-steroid is an important step, but changes in the alkyl side chain at C-17 have little or no effect.

Effects of visual experience on the maturation of the efferent system to the corpus callosum

IN normal adult cats the first and second visual areas (V_1 and V_2) in the two cerebral hemispheres are interconnected through the corpus callosum (CC) by neurones (callosal neurones) which have a characteristic laminar location and are restricted to the region of the boundary between cytoarchitectonic areas 17 (V_1) and 18 (V_2)[1–4]. Callosal neurones acquire this distribution postnatally by disappearing (dying, or eliminating their callosal connections) from most of areas 17 and 18 and decreasing in number in layer VI (refs 5, 6). Here we show that although kittens deprived of pattern vision by binocular lid suture still develop an apparently normal distribution of callosal neurones, monocularly deprived or enucleated, or bilaterally squinted kittens retain to adulthood some callosal neurones in parts of area 17 where such neurones are not normally found. Thus, visual experience can influence the selection of callosal neurones although this selection is probably influenced by more than one factor.

The distribution of callosal neurones in 9 abnormally reared (Table 1) and 14 normal control[1,4] cats was determined by the retrograde transport of horseradish peroxidase (HRP) injected at 10–12 sites within the contralateral visual cortex. One month

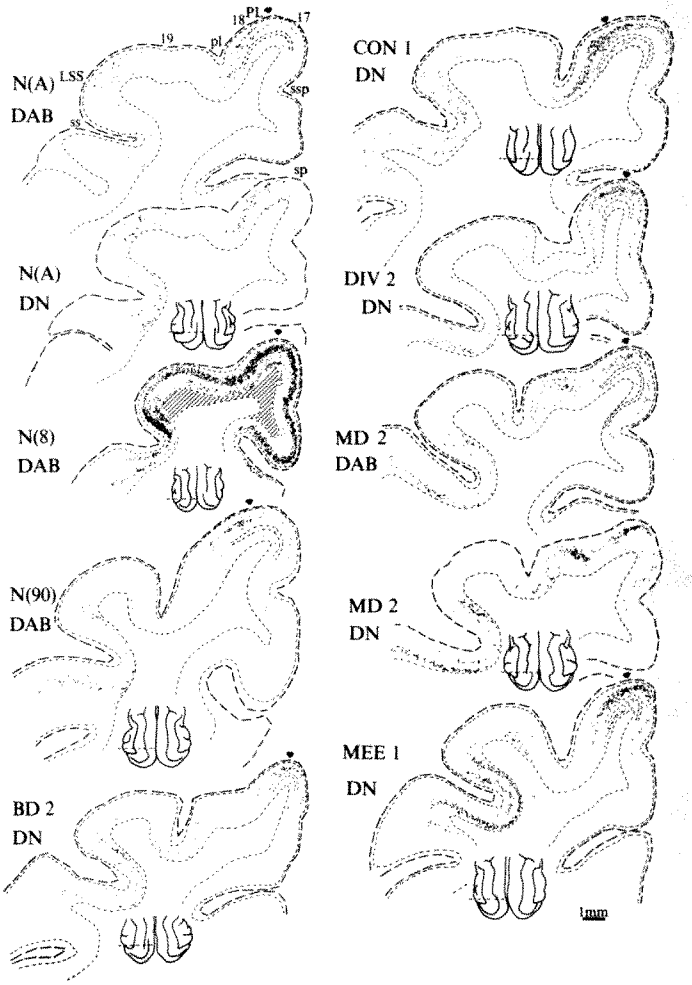

Fig. 1 Computer microscope[26] charts of the distribution of HRP-labelled callosal neurones in 80-μm thick coronal sections at comparable rostrocaudal levels of the visual cortex in different animals. Multiple, 0.5-μl injections of HRP (Boehringer grade I, 33% in sterile saline) were placed in the contralateral cortex. After a 2-day survival time, adjacent, 1-in-4 series of 80-μm sections of each brain were processed with diaminobenzidine (DAB)[1,4] and *O*-dianisidine (DN)[27]. Adjacent sections were reacted with the two substrates as shown for the normal adult, N(A), and for MD 2. In all animals, the injected postlateral and lateral gyri (areas 17, 18, 19) were invaded almost completely by dark HRP precipitate; HRP-filled neurones were found over most of the mediolateral extent of the ipsilateral lateral geniculate nucleus. Each HRP-labelled neurone is represented by a black dot. The level of each section is indicated on the inset drawn from a dorsal view photograph of the corresponding brain. In each section the thin, interrupted lines mark the lower boundaries of layers I, IV, V and VI (in N(8), lower boundaries of layers IV and V are not shown). In the DN sections from N(A) and MD 2 only the lower boundary of layer VI is marked. Cross hatching in N(8) indicates a region of displaced (migrating?) neuronal somata. The two kittens N(8) and N(90) come from a different study[5,6]. Their ages at the time of HRP injection were 8 and 90 days, respectively. Abbreviations: ss, pl, ssp and sp: suprasylvian, postlateral, suprasplenial and splenial sulci, respectively. PL: postlateral gyrus. LSS, 19, 18 and 17 indicate the lateral suprasylvian visual areas, and areas 19, 18 and 17, respectively. The arrow indicates the boundary between the latter two areas.

before death, the strabismic animals could visually guide their paws with either eye; single unit recording from their areas 17 and 18 between the time of HRP injection and death showed that unlike normal cats, but as in monocularly squinted cats[7], most cortical neurones had monocular receptive fields.

In normal adult cats, the cortical volume containing callosal neurones (callosal efferent zone; CZ) consists of two radially separated laminae, located in layers III/IV and VI(subzones a and c, respectively). Subzone a is wider and richer in callosal neurones. Its medial boundary can extend to the crest of the lateral–postlateral gyrus in area 17 (Figs 1, 2, N(A)) and occasionally, at rostralmost levels, as far as the suprasplenial

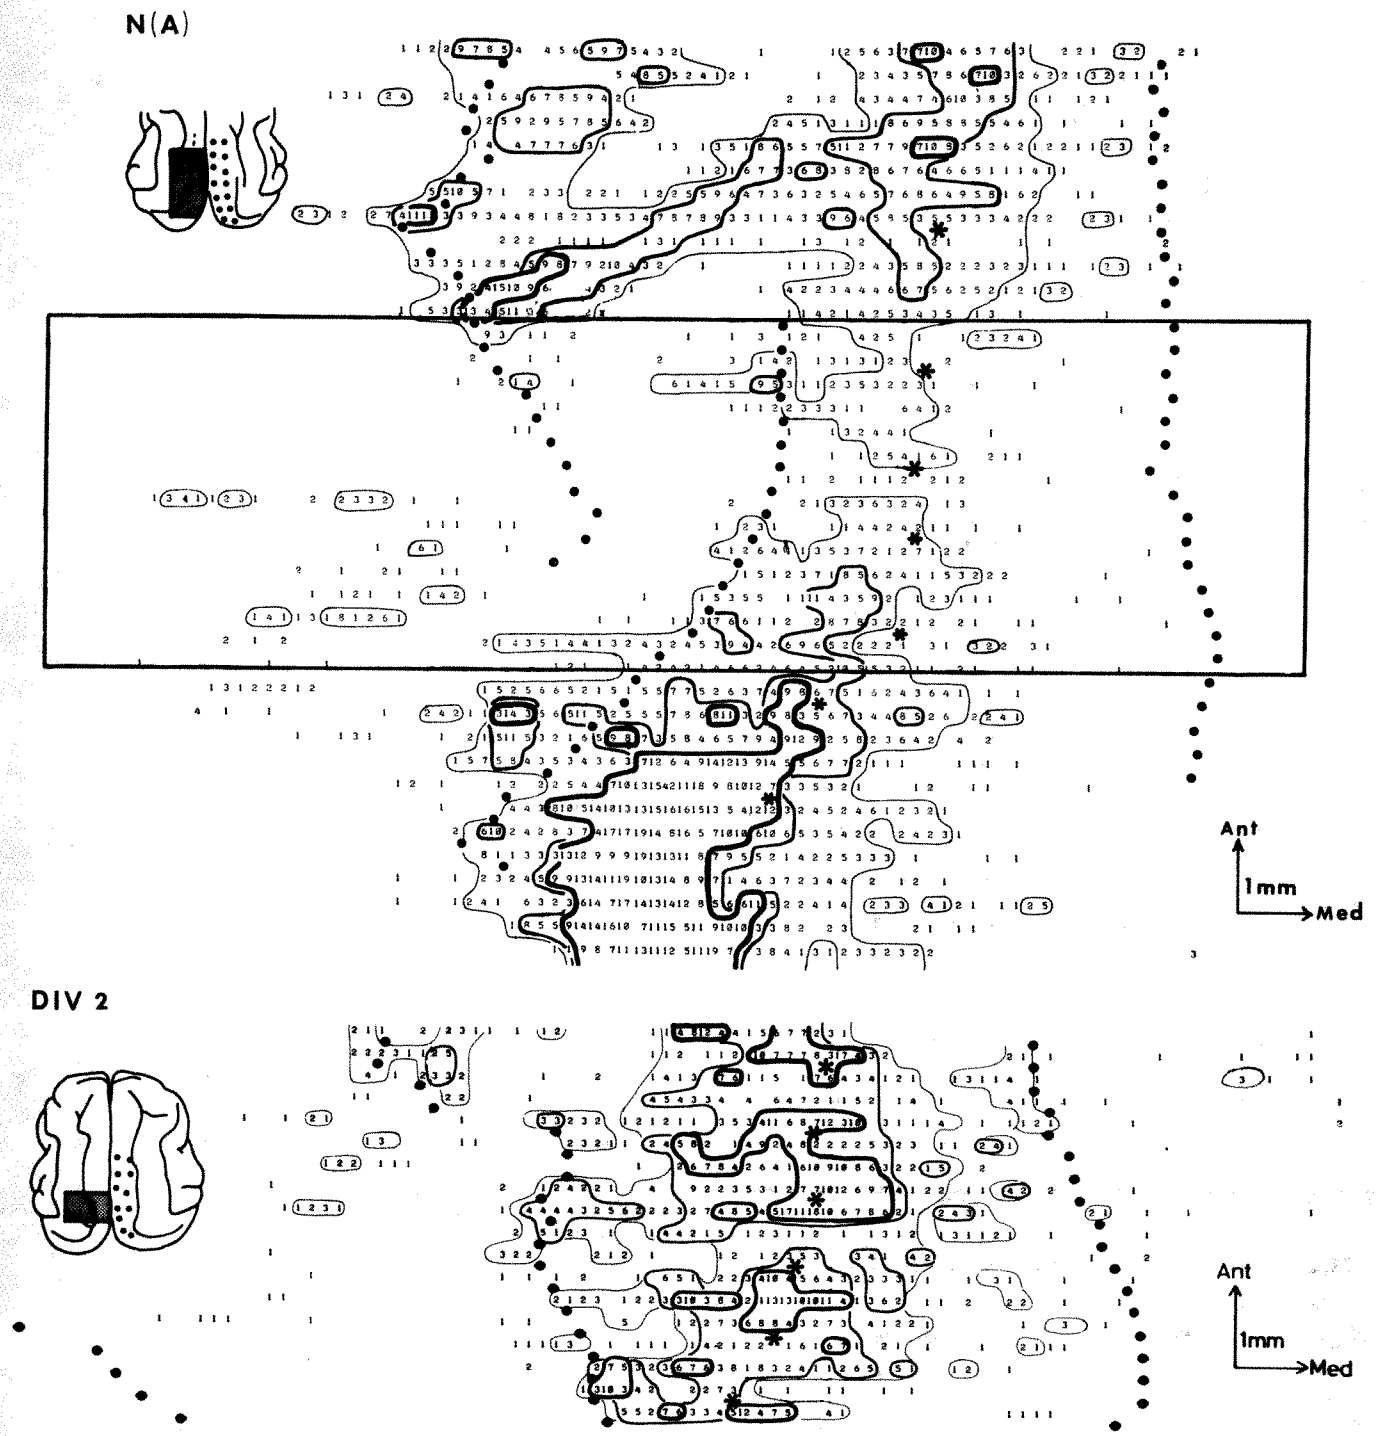

Fig. 2 Computer reconstructions of part of callosal subzone a in a normal adult cat (N(A)) and in a cat raised with divergent strabismus (DIV 2), processed with *O*-dianisidine. Flattened views of the postlateral and lateral gyri (stippled area in dorsal view insets). Dotted lines indicate, from left to right, the fundi of the lateral, postlateral and suprasplenial sulci. A rarely seen branch of the postlateral sulcus was found in DIV 2. The asterisks mark the boundary of areas 17 and 18. The part of the reconstruction of brain N(A) within the rectangle corresponds in rostrocaudal coordinates to the part reconstructed for DIV 2. The neurones in layers II–IV of each section were projected onto a line running parallel to the pial surface and 400 μm deep; the line was then divided into bins of 200 μm. Each horizontal row of numbers in the reconstruction represents the counts of labelled cells for each bin of one section. Contour lines of increasing thickness are drawn around regions where the summed count for any two adjacent bins is 1, 2 and 4 times, respectively, the average count for individual bins (all bins containing at least one labelled neurone were used to obtain this average). The sections were spaced 320 μm apart in N(A) and 280 μm apart in DIV 2. Because of this, the scales of the rostro-caudal axes in the two reconstructions are different. Sites of injection are marked by dots on the insets. For each animal, the homogeneity of the injection site was judged from that of retrograde labelling in the ipsilateral lateral geniculate body.

Table 1 Experiments on the effects of abnormal visual experience on the development of the CZ

Animal	Age at first operation and at death‡	Angle of squint (deg)
BD 1	7; 128	
BD 2	6; 141	
MD 1*	8; 173	
MD 2*	8; 146	
CON 1†	8; 250	26
CON 2†	9; 246	39
DIV 1†	9; 288	33
DIV 2	6; 349	45
MEE 1*	1; 124	

BD, Binocular lid suture; MD, monocular lid suture; CON, bilateral section of lateral rectus muscles (convergent strabismus); DIV, bilateral section of medial rectus muscles (divergent strabismus); MEE, monocular enucleation. Angle of squint was determined by ophthalmoscopic projection of retinal landmarks in paralysed animals (in normal animals about 3.50 (ref. 25)).

† Electrophysiological experiment.

‡ Day of birth = day 0; eye opening normally around day 8.

sulcus; its lateral boundary is irregular and susceptible to individual variation. However, callosal neurones are generally found along the medial banks and sometimes down to the fundi of the lateral and postlateral sulci.

At the ages at which experimental rearing was started, callosal neurones are found throughout areas 17 and 18 (Fig. 1, N(8)) and (especially in subzone c) are more densely packed than in the adult. In normal animals the callosal neurone distribution is apparently mature at 3 months (Fig. 1, N(90)), 34 days before our youngest kitten was killed.

In the binocularly deprived cats (Fig. 1, BD 2) the mediolateral and radial distributions of callosal neurones seem to be very similar to those of normal adults. The CZ may be slightly narrower and callosal neurones a little less densely packed than in normal cats; additional quantitative data are necessary to decide this point.

In all other experimental animals (Fig. 1, right-hand column), subzone a extends further medially in area 17 than in binocularly deprived and normal animals. Callosal neurones are found along the medial bank of area 17 and reach the fundus of the suprasplenial sulcus along almost all its rostrocaudal extent. In CON 1 and DIV 2 a few neurones are also found in the part of area 17 between the suprasplenial and splenial sulci and in the dorsal bank of the latter (see Figs. 1, 2). Because of the normal irregularity and variability of the lateral border of the CZ, it is difficult to determine whether the CZ is also wider than normal in area 18. It is not narrower, so that the presence of callosal neurones in the medial part of area 17 cannot be ascribed to an overall medialward displacement of the CZ.

In the monocularly enucleated cat (Fig. 1, MEE 1) subzone c contains more callosal neurones than in normal or in the other experimental animals.

These results indicate that visual experience can affect which juvenile callosal neurones (or axons) are stabilised and/or which are eliminated, although it is possible that it induces formerly non-callosal neurones to produce callosal axons. The present limited effects suggest either that we did not find the most effective paradigm of visual deprivation or, more likely, that information of non-visual origin is also used in the development of the CZ. There seem to be two possible sources for such information: (1) the topographic (or retinotopic) organisation of structures projecting to or receiving from the cortex containing the callosal neurones; (2) an innate programme within the callosal neurones themselves.

The abnormal distribution of callosal neurones and terminals in Siamese cats[2,8] seems to support the first possibility. However, the development of callosal connections in binocularly deprived Siamese cats must be investigated to differentiate the effects of genetic abnormalities in the retino-geniculo-cortical topology from those of strabismus, which also affects this genotype. The mechanisms, time course and site of action of factors influencing the development of the CZ remain to be determined. The enlargement of the CZ may be related to the almost complete loss of binocular responsiveness of cortical neurones provoked by strabismus[7], monocular deprivation[9] or enucleation.

The reduction of the CZ is probably one aspect of a more general ontogenetic diminution of neurones and/or neuronal connections (for examples see refs 10–13). Our results and those obtained in Siamese cats[2,8], chicks[14] and monkeys[13,15] suggest that transitory neonatal connections can provide a substrate for the plasticity of neuronal connectivity. However, after transitory callosal neurones have been eliminated modifications of callosal terminals may still occur[16].

One functional consequence of the enlarged CZ is related to the fact that the tangential position of callosal neurones determines their receptive field location. Thus, the receptive fields of callosal neurones in the expanded CZ probably include an abnormally large portion of the visual field. However, they should still be concentrated near the vertical meridian[8,17–19], represented at the 17/18 border[20,21].

Callosal neurones are thought to integrate the cortical representation of the visual field and subserve binocular interactions contributing to stereopsis and possibly eye movements (for reviews see refs 22, 23). In the amphibian *Xenopus laevis*, binocular vision seems to be subserved by intertectal connections whose development is affected by visual experience[24], permitting compensation for normal or experimentally induced changes in ocular alignment. It is attractive to view the modifications we observe in the cat CZ as partial compensation for the disturbance of the binocular visual field, although the adaptiveness of the changes remains to be demonstrated.

This work was supported by Swiss NSF grant 3.319.0 78 to G.M.I., D.O.F. received a fellowship from the American-Swiss Federation for Scientific Exchange.

Note added in proof: Three more kittens deprived of vision by bilateral eyelid closure for 1–4 months after birth have now been examined. In all these animals MRP-labelled callosal neurones were fewer than in normal cats and showed radial and tangential distributions similar to that of binocularly deprived animals described above. Quantitative analysis of the reduction in number of callosal neurones following binocular deprivation is under way.

Electroconvulsive shock treatment decreases β-adrenergic receptor sensitivity in rat brain

ELECTROCONVULSIVE SHOCK (ECS) is one of the most effective forms of therapy available for patients with depression[1]. Its mechanism of action, however, is not clear. Like other antidepressants, ECS probably augments the postsynaptic availability of neurotransmitters, for it increases the release and turnover of noradrenaline (NA)[2–4], decreases NA uptake[5], and raises the activity of tyrosine hydroxylase. Also, synthesis of cyclic AMP stimulated by NA (NA-sensitive adenylate cyclase) is reduced in brain tissues obtained after chronic treatment with ECS[6,7]. It has been reported that chronic administration of antidepressant drugs reduces β-adrenergic receptor density in the rat brain[8]. Because ECS is another form of treatment for depressive illness, we examined whether chronic administration of ECS has effects similar to those of other antidepressants on β-adrenergic receptor sensitivity in rat brain. We report here that we observed a significant decrease in β-adrenergic sensitivity following chronic ECS treatment. The relationship between such observed effects and clinical response requires further investigation.

Binding studies with radiolabelled ligands like ^{3}H-dihydroalprenolol (^{3}H-DHA) or ^{125}I-hydroxybenzylpindolol (β-adrenergic antagonists) have been used for identification and characterisation of β-adrenergic receptors in the brain[9–11] and other tissues[12]; thus, they provide a method for direct quantitation and study of the kinetic properties of these receptors.

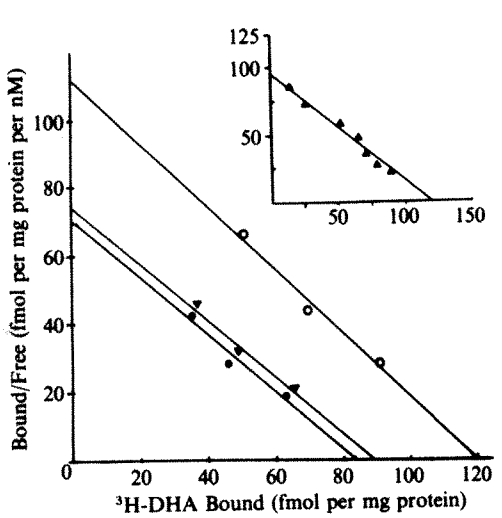

Fig. 1 Scatchard analysis of specific ^{3}H-DHA binding to the brain particulate fractions obtained from control rats (○), DI-treated rats (●) and ECS-treated rats (▲). The experimental conditions are described in Table 1 and each point is the mean obtained from six animals. Receptor density (B_{max}) and dissociation constant (K_D) were calculated from this figure and are shown in Table 1. Inset: Experimental conditions are described in Table 1. The specific ^{3}H-DHA binding to particulate fractions was determined as a function of increasing ^{3}H-DHA concentrations (0–4.5 nM) in a control rat. Scatchard analysis of the obtained data as shown in the inset gave a B_{max} of 115 fmol ^{3}H-DHA bound per mg protein and an apparent K_D of 1.12 nM. This experiment is one of several experiments carried out in identical conditions and giving similar results.

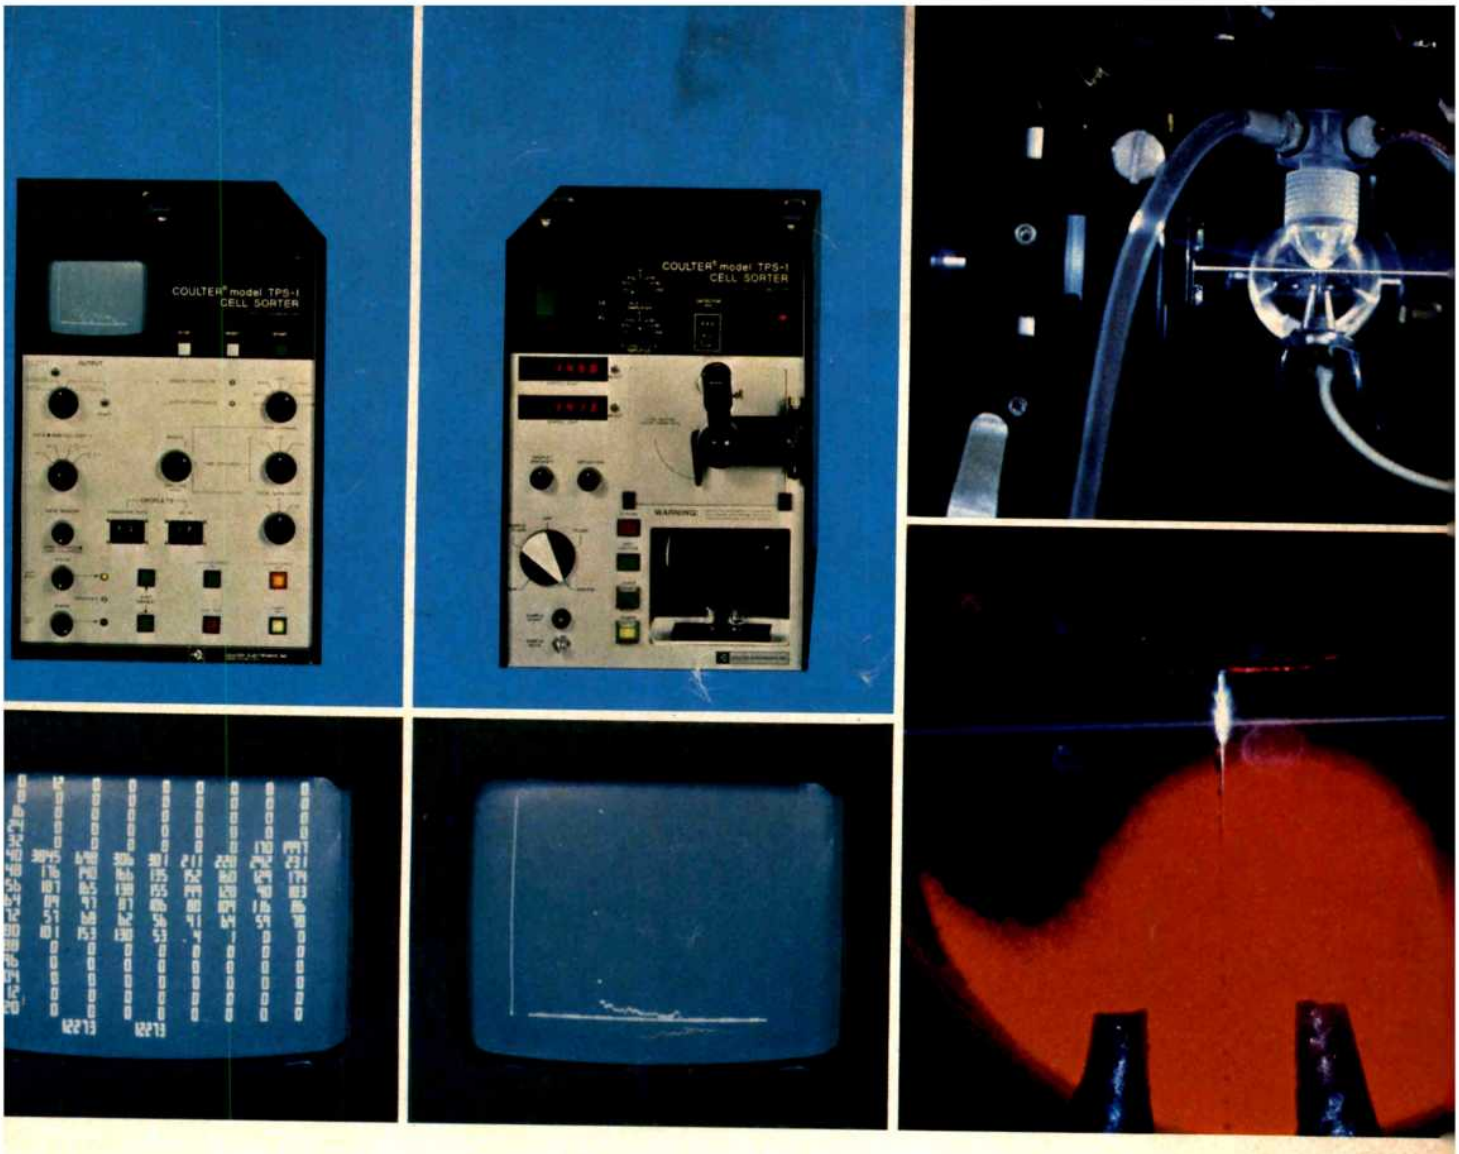
Table 1 Effect of chronic treatment with desipramine and electroconvulsive shock on receptor density and dissociation constant of β-adrenergic receptors in rat brain homogenates

Treatment	Receptor density (fmol per mg protein)	% of control	*P* values as compared with control	Dissociation constant (nM)
Control ($n=6$)	119±8.8			1.06±0.05
Desipramine ($n=6$)	84±3.5	71	<0.001	1.19±0.06
ECS ($n=6$)	87±3.5	73	<0.001	1.14±0.06

Male Sprague–Dawley rats (100–150 g) were subjected to ECS (75 mA for 1 s through transcorneal electrodes) once daily for 12 d. Another group was injected with despiramine (10 mg per kg, intraperitoneally) once daily for the same period. Control rats were injected with normal saline and were handled similarly to the ECS rats, but did not receive shocks. The rats were killed 1 h after the last treatment, and the cortices were removed, homogenised in 50 volumes (w/v) of Tris buffer (0.05 M, *p*H 7.4), and spun at 49,000*g* for 10 min. This process was repeated, and the pellet was finally suspended in Tris buffer. Binding of ^{3}H-DHA was carried out in triplicate by incubation of an aliquot of the suspension (0.3–0.5 mg protein) with ^{3}H-DHA at three concentrations (between 0.4 and 4 nM) in Tris buffer in a final volume of 1 ml, with or without 1 μM (−)propranolol, at 23 °C for 15 min. ^{3}H-DHA bound to the membrane was separated by filtration through a Whatman (GF/F) filter and washed three times with 4 ml buffer. The filter was placed in a BBS cocktail and counted in a Nuclear Chicago scintillation spectrometer. Specific binding is defined as the difference between total binding and the binding observed in the presence of 1 μM (−)propranolol. Receptor density, as shown in Fig. 1, was calculated by Scatchard analysis, and is the intercept on the *x* axis (B_{max}). K_D values were calculated by Scatchard analysis; *P* values were obtained by paired *t*-test (two tail).



We therefore measured the binding ^{3}H-DHA to particulate fractions prepared from rat cerebral cortex. The method used was essentially that of Bylund and Snyder[9], and we obtained binding characteristics similar to those they reported. The binding was rapid, stereospecific to β-adrenergic agonists and antagonists and showed saturation kinetics similar to those reported. Scatchard analysis of the ^{3}H-DHA binding to rat cerebral cortex resulted in a straight line, indicating a single class of high-affinity receptors (Fig. 1, inset). The maximum number of binding sites (receptor density) observed (115 fmol per mg protein) and the observed apparent dissociation constant (1.12 nM) were also similar to those previously reported[8,9].

The effects of chronic treatment with ECS and desipramine (DI) on β-adrenergic receptor sensitivity (Table 1) were assessed by determining the maximum number of ^{3}H-DHA binding sites by Scatchard analyses (Fig. 1). Binding of ^{3}H-HDA to particulate fractions obtained from the cortex was carried out at three different concentrations of ^{3}H-DHA. The observed mean β-adrenergic receptor density for the control rats was 119±8.8 (fmol ^{3}H-DHA bound per mg protein). DI caused a 29% reduction in receptor density ($P<0.001$), in agreement with the results reported by Banerjee *et al.*[8]. Treatment with ECS resulted in a 27% decrease ($P<0.001$) in density. The mean apparent dissociation constants (K_D) of ^{3}H-DHA binding, determined by Scatchard analysis (Fig. 1), were similar for the treated and control rats (Table 1), indicating that the receptor density changes were not related to alterations in the affinity of receptors.

These results thus indicate that chronic ECS treatment produces a reduction in the sensitivity of β-adrenergic receptors in rat brain. This effect is similar to the effects of other antidepressants, for example, DI, presented here, and DI, doxepin and iprindole, reported by Banerjee *et al.*[8]. The results also suggest that a decrease in NA-stimulated synthesis of cyclic AMP in rats chronically treated with ECS, as reported previously[6,7], may be related to a decrease in β-adrenergic receptor sensitivity.

Treatment with ECS causes increased release and turnover of NA[4,5,13] and possibly of dopamine in various areas of the rat brain. Tricyclic antidepressants, on the other hand, inhibit reuptake of biogenic amines in synaptosomal preparations[14], and drugs like pargyline and phenelzine inhibit monoamine oxidase activity. These antidepressants have different modes of action

Fluorescence, light scatter, cell sortinc

Coulter has a family of compact, reliable instruments that can help you investigate a wide range of cytochemical, histochemical and immunological characteristics. They are the COULTER® Model TPS Cell Sorters.

Select from 5 watt, 2 watt, or 0.1 watt lasers, one or two color analysis, UV capability and other features to meet your research needs.

Study immunological response, the DNA or protein content of a cell, its surface structure, whether it is alive or dead, how big it is and many other things based on laser-induced fluorescence and/or light scattering.

TPS Systems analyze at rates up to 10,000 cells per second. They also physically sort out cells of interest based on operator-selected parameters at rates up to 4,000 cells per second.

Let us demonstrate the TPS System's flexibility and simplicity in your lab.

For a demonstration or more information on the COU TPS family, just fill out the coupon below and return it or call the Coulter office nearest you.

Yes, I am interested in hearing more about th COULTER® TPS Cell Sorters.

☐ Please arrange a demonstration in my lat oratory.
☐ Send me more information right away.

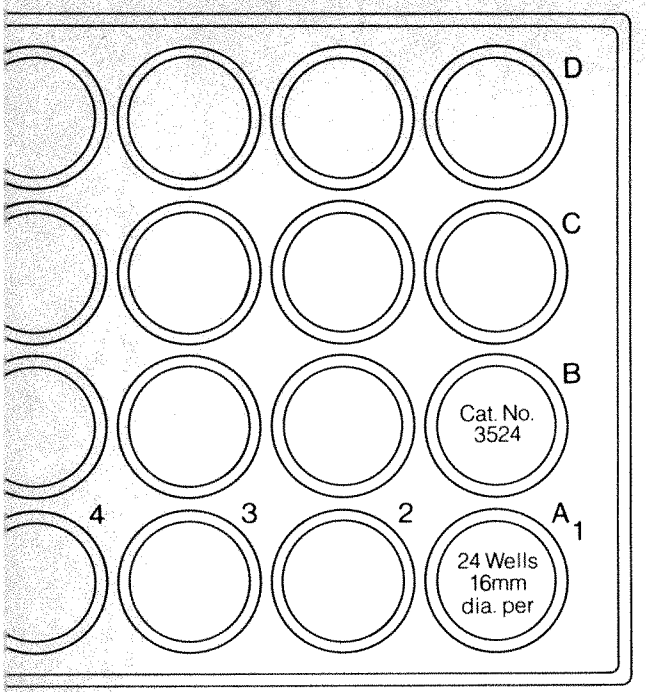
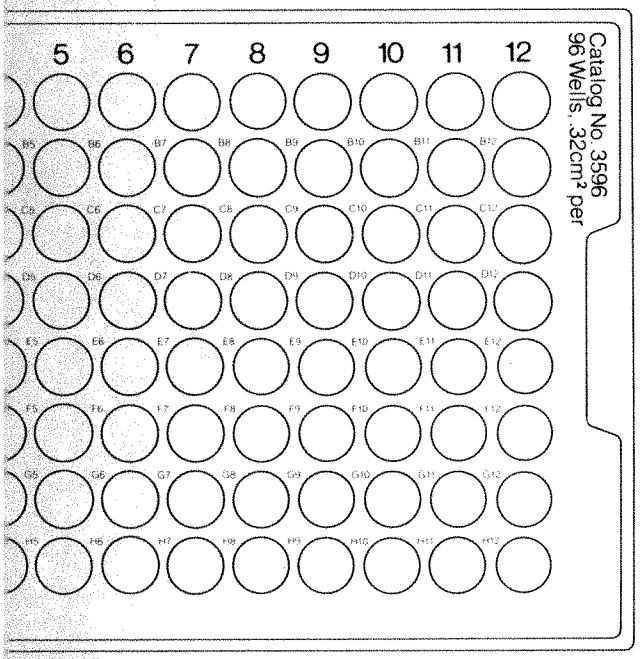
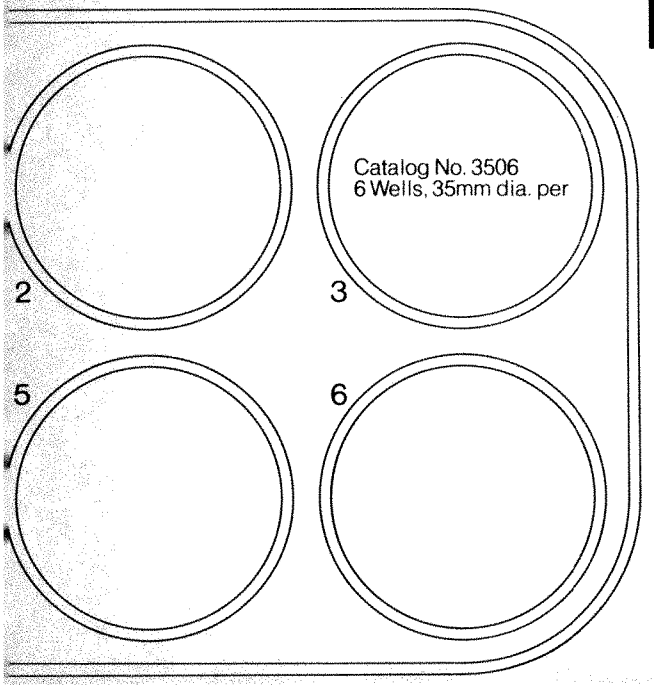
Be an aggressive buy



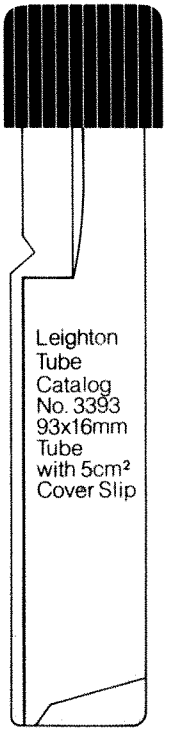
COSTAR DISPOSABLE LABWARE: Good ideas and high
combined. Precision molded and radiation sterilized. New STRIPE
pipettes in three sizes. Flasks, dishes, and cluster plates are highly
polished and distortion-free, with frosted labeling surfaces
where useful. All are subjected to our tough Q.C. screening.



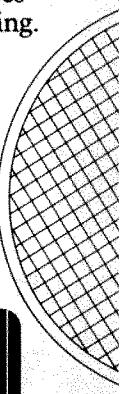
Cluster Plates: Every well numbered so you work quickly and accurately. And rimmed so media stays where it belongs. Plus non-reversible covers with built-in condensation rings to prevent cross-contamination.



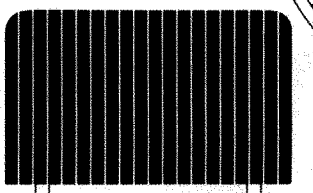
Rectangular Flasks: Deep skirted, easy on/off caps. Graduated media markers for accurate filling without using a pipette. Frosted labeling surfaces.

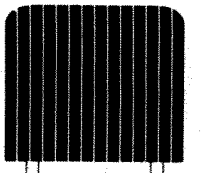


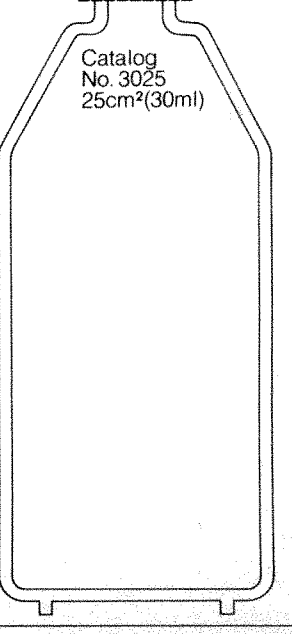
Triangular Flasks: Sloping shoulders and extra-wide necks let you reach every square centimeter—even the upper corners. Frosted labeling surfaces.

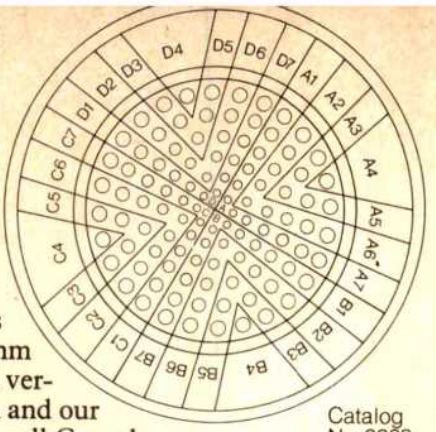


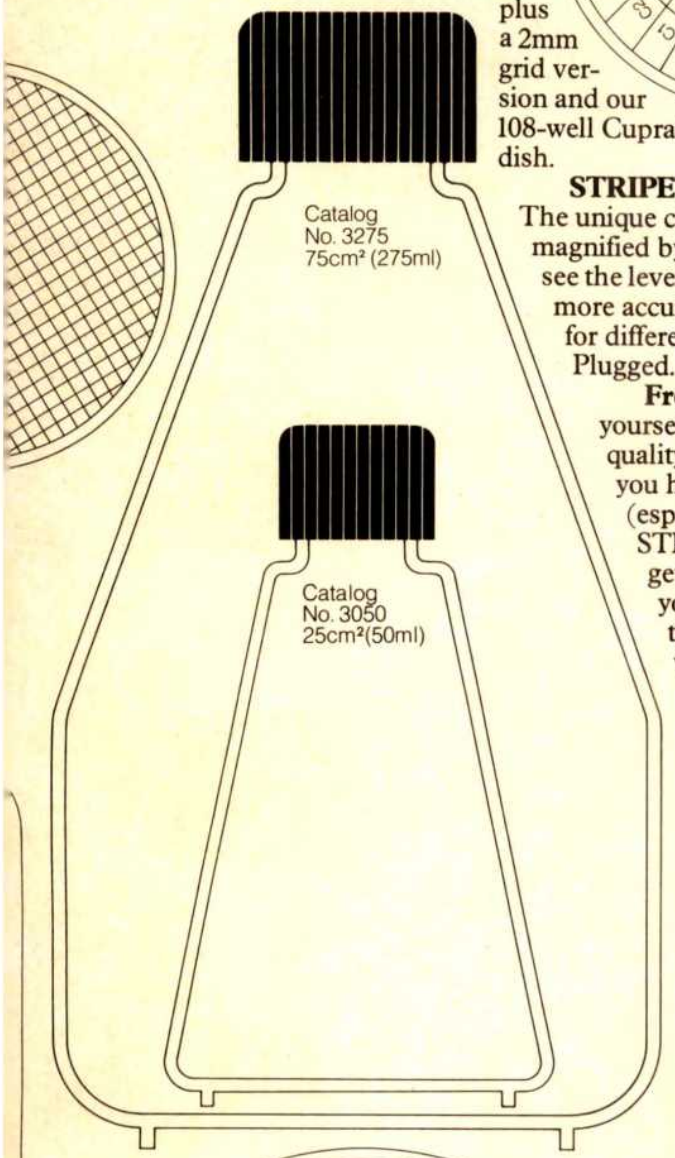
Leighton Tube: The first disposable plastic one for your basic tissue culture needs and E.M. Non-slip handle for the cover slip. Slide is scribed across the middle with each half numbered. Treated cover slip, untreated tube helps prevent unwanted cell attachment.





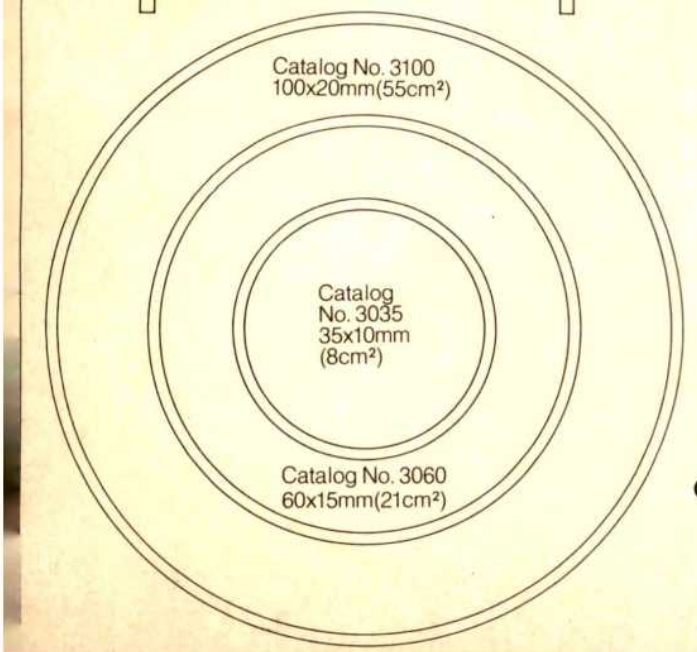


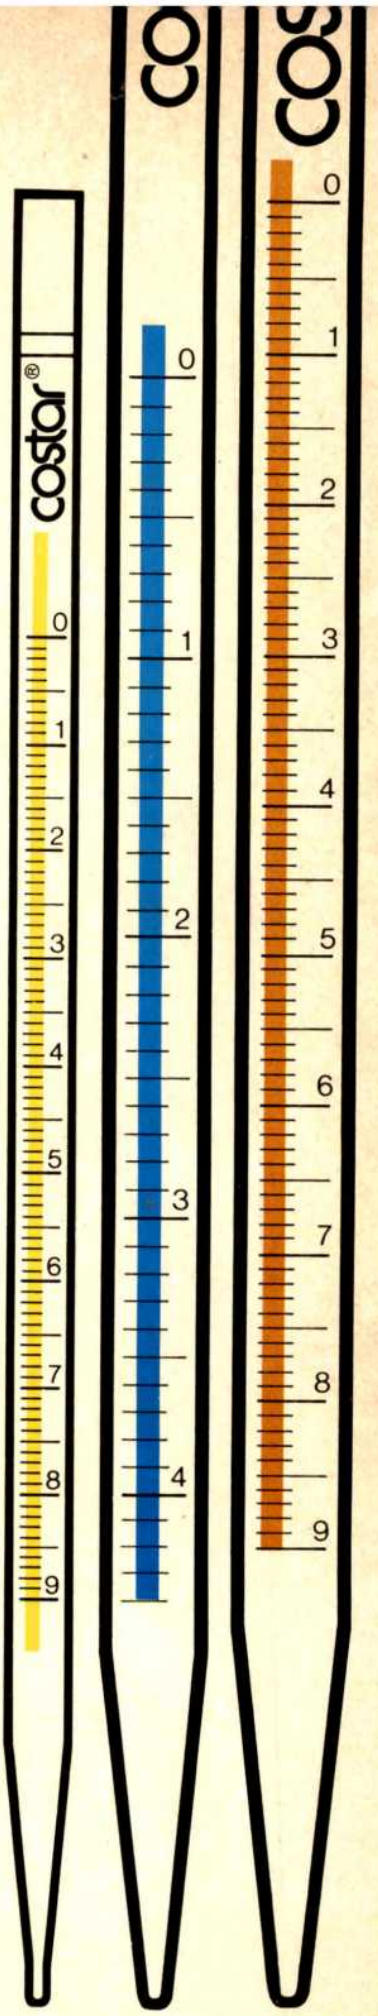




.....We'll be ready.

Dishes: Three sizes plus a 2mm grid version and our 108-well Cuprak dish.





Catalog No. 3268
108 Wells in 6 Sizes

STRIPETTE Pipettes: The unique color stripe, magnified by the reagent, lets you see the level easier and measure more accurately. Different colors for different sizes—1ml, 5ml, 10ml. Plugged.

Free Samples: See for yourself that we really mean quality. Call or write for what you haven't tried already (especially some STRIPETTES). Then let's get down to the name of your nearest dealer and that aggressive buying we mentioned earlier.

REACTI·WARE® Micro·Tissue Grinder Kit

Applications:
Biochemistry
Immunology
Microbiology
Pathology
Pharmacology
Tissue Culture

FEATURES:

- Milligram to microgram sample handling with minimal loss.
- Greater yield of enzyme activity due to reduced heat build-up in small sample grinders.
- Minimized sample transfer.
- Ground glass surfaces for homogenizing connective tissue (e.g. sketal muscle, heart, lung and intenstine).
- Polished glass to Teflon surfaces for processing soft tissue (e.g. brain and liver).
- Polished glass to polished glass grinding surfaces for the recovery of intact nuclei and homogenizing bacteria and malignant tissue.
- Option of delicate hand operation or power homogenization.
- Kit packaged in high density polyethylene case for neat, convenient storage and protection.

20017 **Micro-Tissue Grinder Kit,** *Complete* 99.95

on the biogenic amine system; however, all increase the biogenic amine concentration in the postsynaptic area, and reduce the sensitivity of β-adrenergic receptors[8] and the responsiveness of adenylate cyclase to NA, as reported by others[6,7,15,16] and presented here. Furthermore, Deguchi and Axelrod[17] and others[12] have suggested that continued exposure of adenylate-cyclase-coupled β-receptors to elevated levels of agonists lowers the sensitivity of the receptors; we might therefore assume that loss of β-adrenergic receptor sensitivity on chronic treatment with antidepressants is caused by overexposure of postsynaptic β-adrenergic receptors to elevated levels of NA. However, iprindole has no significant effect on re-uptake, release or turnover of catecholamines[18], and it is not certain whether it increases the levels of NA in the synaptic cleft; like other antidepressants, it reduces β-adrenergic receptor sensitivity[8] and decreases NA responsiveness of adenylate cyclase[16]. Therefore, as suggested by Banerjee *et al.*[8], other mechanisms may also be involved in the development of the reduction in β-adrenergic receptor sensitivity.

The clinical effects of antidepressants are observed only after 1–3 weeks of treatment. As the effects of antidepressants on β-adrenergic receptor sensitivity are observed after a similar treatment period, the two may be closely related. However, the time course of development of reduced β-adrenergic receptor sensitivity must be studied before such a relationship can be confirmed. It is also possible that the effects of antidepressants on β-adrenergic receptor sensitivity are secondary to their effects on the catecholamine systems.

How does adrenaline accelerate the heart?

THE way in which adrenaline acts on the sinoatrial (SA) node to accelerate the heart rate has hitherto been obscure. However, in various other parts of the heart adrenaline increases the slow inward (Ca^{2+}/Na^{+}) current[1–4], and voltage-recording experiments have indicated that adrenaline also has this action in the sinus region[5–7]. In the voltage-clamp experiments reported here, we find that adrenaline does indeed increase the slow inward current in the SA node of the rabbit, but that it also augments the outward current which would tend to decelerate pacemaker depolarisation. We find that an additional current, i_t, is activated within the range of voltage where the pacemaker depolarisation occurs: this could be important both in normal pacemaking and in adrenaline-induced acceleration.

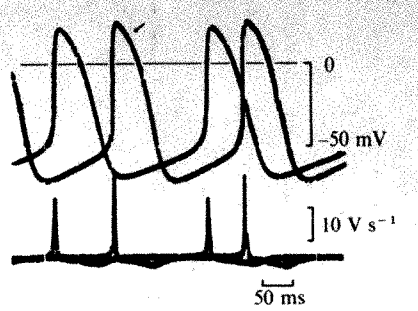

Fig. 1 Intracellular record of spontaneous activity in the rabbit SA node before and during (trace indicated by arrow) perfusion with adrenaline, 5×10^{-8} M. Lower trace shows the rate of change of voltage. In this and in the following figures traces have been recorded on tape during the experiment and overlapped on a storage oscilloscope on replay.

Figure 1 shows the effect of adrenaline on the intracellular voltage record and the rate of change of voltage (dV/dt) in a small, spontaneously firing preparation (about 0.3 mm × 0.3 mm) from the rabbit SA node. The overshoot of the action potential increases, as does dV/dt during the upstroke. As any fast sodium current present was blocked by the presence of tetrodotoxin (5×10^{-7} g ml^{-1}) these effects are probably caused by an increase in the slow inward current[8]. Figure 1 also indicates that the adrenaline produces a slightly more negative maximum diastolic potential, and an acceleration of the rate of repolarisation, both of which imply an increase of total membrane current in the outward, rather than the inward direction.

Voltage clamp of SA nodal tissue is much more difficult than that of other cardiac tissues; only recently has a method, pioneered by Noma and Irisawa[13], been developed for successfully clamping the mammalian sinus. In this, very small (0.3 mm × 0.3 mm) preparations which are still spontaneously active are dissected from the SA node and voltage clamped using two microelectrodes. Good voltage-clamp results can be obtained over a range of potentials, including the pacemaker range, although in response to large depolarisations and hyperpolarisations voltage control is often lost.

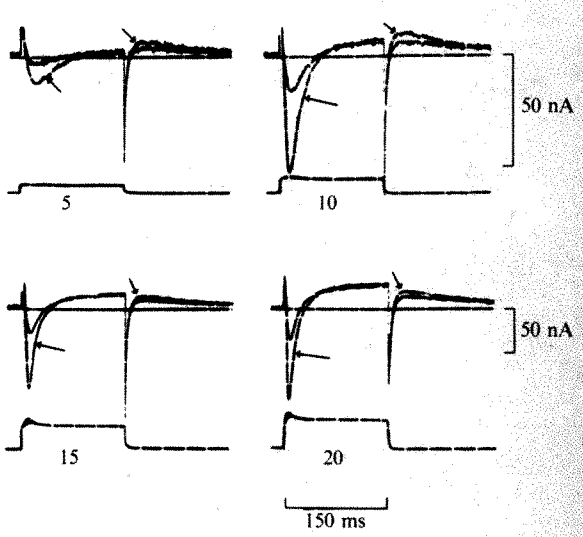

Fig. 2 Increase of $i_{Ca/Na}$ and i_K in adrenaline. Voltage-clamp depolarisations of 5, 10, 15 and 20 mV from a holding potential of −45 mV (lower traces in each panel) were given before and during the action of adrenaline, 5×10^{-7} M. All current traces recorded in adrenaline (indicated by arrows) have been shifted upwards by 2 nA. Solid lines represent zero current.

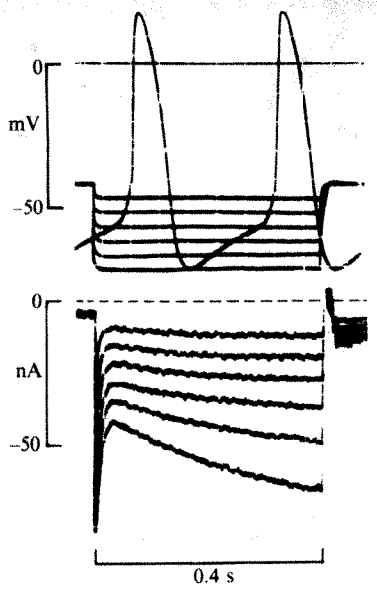

Fig. 3 *a*, Superimposition of pacemaker activity and voltage-clamp hyperpolarisations from a holding potential of −42 mV in the same preparation; *b*, currents recorded during the clamp hyperpolarisations. Note that the time-dependent changes in i_f are greater at more hyperpolarised levels.

With this method it can be shown that in the rabbit SA node adrenaline does indeed increase both slow inward current ($i_{Ca/Na}$) and outward potassium current (the current termed i_K by Difrancesco Noma and Trautwein[10]). Figure 2 shows the increase in peak $i_{Ca/Na}$ current caused by adrenaline during a 10-mV depolarising voltage-clamp pulse and the increase in the i_K-current tail recorded on return to the holding potential of −45 mV. These results correlate with previous findings that adrenaline increases both the slow inward and the plateau outward current in other cardiac tissues (for review see ref. 11).

As indicated in Fig. 1, the positive chronotropic effect of adrenaline is mediated by an increased rate of pacemaker depolarisation (PD). An increase of i_K will, however, tend to decelerate the PD. Although the larger $i_{Ca/Na}$ would by itself accelerate the PD in its later stages immediately preceding the upstroke, is it unlikely that combined with the augmented i_K it could account for the increased rate of change of voltage during the whole course of the PD seen in adrenaline.

What, then, is the mechanism of the increased pacemaker rate seen in adrenaline? We have found that an additional current, which has been previously noted in the rabbit SA node[9] and in the frog sinus venosus[12] and which we will call i_f, is important both in normal pacemaker activity and in adrenaline-induced acceleration. Hyperpolarising voltage-clamp pulses from a holding potential of −42 mV (Fig. 3) reveal that i_f is a slowly increasing inward (or decreasing outward) current change whose amplitude increases with the clamp pulse amplitude. In Fig. 3 the voltage protocol has been superimposed on a record of spontaneous activity in the same preparation to show the relevance of i_f to the potential range of the pacemaker depolarisation. Addition of adrenaline, 10^{-7} M, causes a substantial and reversible increase in the time-dependent change of i_f, as shown in Fig. 4. In the unclamped preparation such an increase would cause a faster PD, as observed during adrenaline action in Fig. 1.

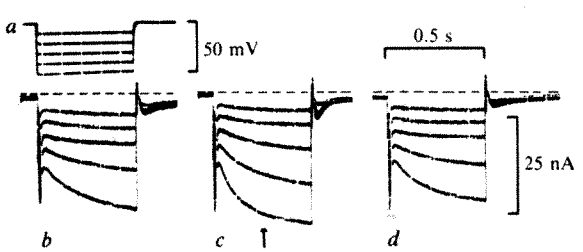

Fig. 4 Increase of i_f in adrenaline. i_f changes are activated by voltage-clamp hyperpolarisations from a holding potential of −36 mV. *a*, Voltage protocol used throughout the experiment; *b*, control; *c*, during adrenaline, 10^{-7} M; *d*, return.

Investigating the ionic nature of the i_f current system is difficult as it is not possible to hyperpolarise the small preparations used by more than 50 mV without risking membrane injury and consequent breakdown of the voltage clamp. We have therefore been unable to determine whether i_f has a reversal potential close to the equilibrium potential for K^+ ions, that is, at about −100 mV, which would show whether or not it could be equated with the i_{K_2} current of the Purkinje fibre. Nevertheless, the resemblance to i_{K_2} is striking: i_{K_2} is deactivated by hyperpolarisations into the same voltage range as i_f and the change in i_f produced by adrenaline strongly resembles that produced in i_{K_2} by a voltage shift of its kinetics. Regardless of whether it becomes possible to test this resemblance further experimentally, it is already clear that i_f has an important role both in normal rhythmic activity in the SA node and in mediating the response to adrenaline.

Role of the dendritic release of dopamine in the reciprocal control of the two nigro-striatal dopaminergic pathways

USING cats implanted with push–pull cannulae, we have previously demonstrated a reciprocal regulation of the activity of the two nigro-striatal dopaminergic pathways. Asymmetric fluctuations in the spontaneous release of dopamine(DA) were simultaneously seen in the two caudate nuclei (CN)[1]. As revealed by the changes in DA release from nerve terminals, the unilateral nigral application of DA[1] or of drugs enhancing the dendritic release of DA, such as amphetamine or benztropine (2), reduced the activity of ipsilateral dopaminergic neurones and induced an opposite effect in the contralateral side. Conversely, the unilateral nigral blockade of dopaminergic transmission by local application of neuroleptics enhanced the release of DA in the ipsilateral CN and decreased the transmitter release in the contralateral structure[2]. Opposite changes in the release of DA were also seen in the two CN under unilateral delivery of sensory stimuli[3] or during unilateral electrical stimulation of the cerebellar dentate nucleus[4]. These latter effects were associated with asymmetric changes in the dendritic release of DA in the two substantia nigrae (SN) which were in an opposite direction to those seen in the two CN (an increased

0028-0836/79/290236—04$01.00

© Macmillan Journals Ltd 1979

release of DA from nerve terminals corresponded to a decreased release of the transmitter from dendrites and vice versa). These experiments indicated that DA which is released from dendrites in one SN regulates the activity of the ipsilateral dopaminergic neurones; they also suggested that it contributes to the control of the contralateral dopaminergic neurones by influencing the dendritic release of DA in the contralateral SN. This hypothesis was confirmed in the present study by measuring the changes in DA release from nerve terminals and dendrites of the two pathways under pharmacological blockade or facilitation of dopaminergic transmission in one SN.

Adult cats of both sexes were anaesthetised with halothane and implanted with four push–pull cannulae (0.9 mm diameter), one in each SN and each CN, to measure continuously the release of ^{3}H-DA synthesised from ^{3}H-tyrosine, as previously described[5]. An artificial cerebrospinal fluid (CSF) containing ^{3}H-tyrosine (50 Ci mmole^{-1}, 50 μCi ml^{-1}) was introduced in each structure at a rate of 1 ml h^{-1} and ^{3}H-DA was estimated in serial 10-min superfusate fractions. ^{3}H-DA was separated from ^{3}H-tyrosine and ^{3}H-labelled metabolites by ion-exchange chromatography and alumina adsorption. α-Methyl-*p*-tyrosine (α-MT, 10^{-4}M), an inhibitor of DA synthesis; or (+)amphetamine (10^{-6} M) were applied to the left SN 22 h after the onset of superfusion of the four structures with ^{3}H-tyrosine to block or facilitate local dopaminergic transmission, respectively.

The unilateral nigral application of α-MT for 60 min markedly stimulated the release of ^{3}H-DA in the ipsilateral CN and induced an opposite effect in the contralateral structure. Moreover, in contrast to that observed in the ipsilateral side, this treatment stimulated the dendritic release of ^{3}H-DA in the contralateral SN (Fig. 1). The unilateral nigral application of (+)amphetamine for 10 min not only induced asymmetric changes in the release of ^{3}H-DA in both CN (as previously shown[2]), but also in both SN. These effects were in opposite directions to those induced by αMT (Fig. 2).

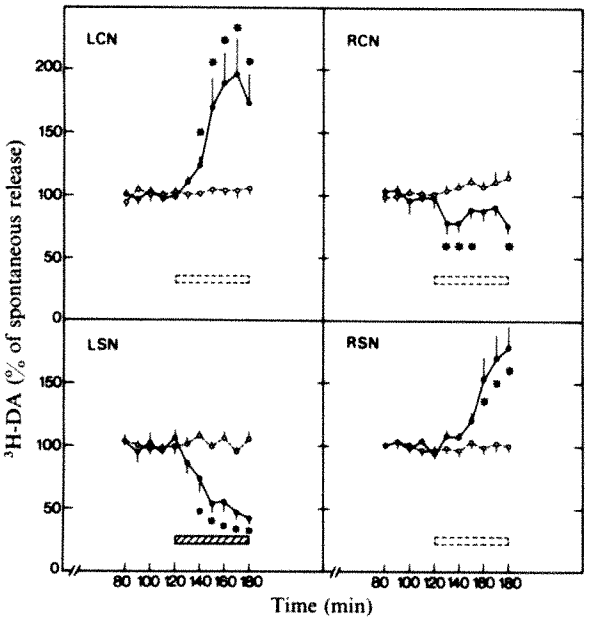

Fig. 1 Effects of α-methyl-*p*-tyrosine application into the left substantia nigra on the release of ^{3}H-dopamine from the two caudate nuclei and the two substantia nigrae. Four push–pull cannulae were simultaneously implanted in the left (LCN) and the right (RCN) caudate nuclei and in the left (LSN) and the right (RSN) substantia nigrae in anaesthetised cats. The four structures were perfused with an artificial CSF containing L[3,5-^{3}H]tyrosine (50 Ci mmol^{-1}, 50 μCi ml^{-1}, 1 ml h^{-1}. ^{3}H-Dopamine (^{3}H-DA) was estimated in 10-min successive superfusate fractions. The average quantities of ^{3}H-DA released in superfusate fractions of the SN (0.4 nCi) and the CN (0.6 nCi) were, respectively, 20 and 30 times the blank value. α-Methyl-*p*-tyrosine (α-MT, 10^{-4} M) was introduced for 60 min into the CSF superfusing the LSN (hatched bar). In each animal and for each cannula, ^{3}H-DA in each successive fraction was expressed as a percentage of an average spontaneous release calculated from the five fractions collected before the treatment. Data are the mean ± s.e.m. of results obtained with five animals (—•—). $*P < 0.05$ when compared with corresponding control values obtained in five untreated animals (---○---). ▨, α-MT application.

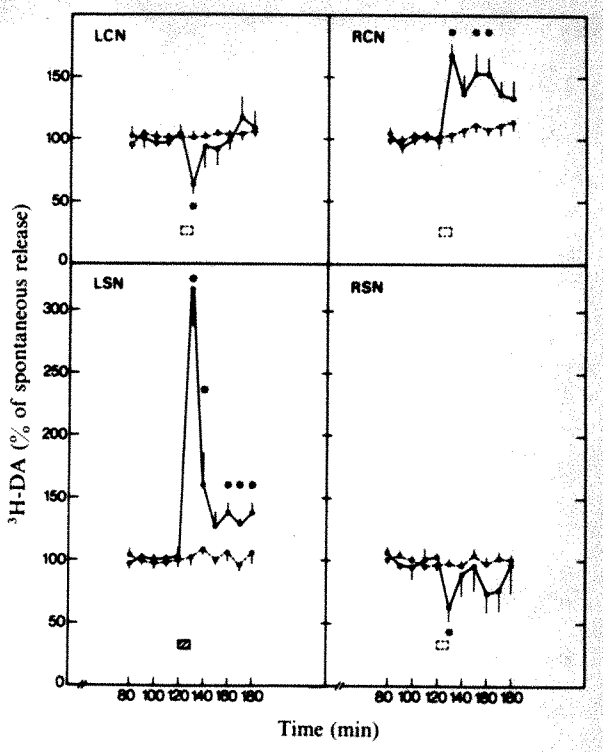

Fig. 2 Effects of (+)amphetamine application into the left substantia nigra on the release of ^{3}H-dopamine from the two caudate nuclei and the two substantia nigrae. Five animals were treated as described in Fig. 1 except that (+)amphetamine (10^{-6} M) was applied for 10 min into the left substantia nigra (LSN). Data are calculated and expressed as in Fig. 1. $*P < 0.05$ when compared with corresponding control values obtained in five untreated cats (---○---). ▨, (+)Amphetamine application.

To confirm that the contralateral effects induced by the unilateral application of α-MT or (+)amphetamine were mediated by the changes in DA release induced in the ipsilateral SN and were not secondary to those observed in the ipsilateral CN, these drugs were applied to the left CN and ^{3}H-DA was simultaneously measured in both CN and both SN. α-MT (10^{-4}M) and (+)amphetamine(10^{-6}M) which, respectively, reduced and enhanced the local release of ^{3}H-DA in the left CN, failed to change ^{3}H-DA release in the contralateral CN or SN (Figs. 3, 4). Also, marked changes in the dendritic release of ^{3}H-DA were seen in the ipsilateral SN (Figs. 3, 4). They were parallel to those detected in the CN, as the dendritic release of ^{3}H-DA was reduced by α-MT and enhanced by (+)amphetamine.

Several conclusions on the influences of DA can be drawn from the present study and are summarised in Fig. 5. First, the activation of ipsilateral dopaminergic neurones induced by the unilateral application of α-MT demonstrates that DA released from dendrites tonically inhibits the activity of the ipsilateral neurones. This may mainly result from a reduced availability of DA at dopaminergic receptor sites located either on dopaminergic cells or their dendrites[6,7] or on nigral afferent fibres[8,9] (Fig. 5*a*). Second, the effects of α-MT and (+)-amphetamine on the dendritic release of ^{3}H-DA imply that these drugs, respectively, stimulated or inhibited the firing rate of the ipsilateral dopaminergic neurones through their effects on

he dendritic release of DA. Thus, the changes in DA dendritic elease induced by local modifications of the dopaminergic ransmission in the ipsilateral CN further support the postuated[10] existence of a striato-nigral neuronal loop controlling the ctivity of the dopaminergic neurones (Fig. 5*b*). Third, the symmetric changes in DA release seen in both CN under the nilateral application of various stimuli[1-4] cannot be related to odifications of ^{3}H-DA release in one of the CN (Fig. 5*c*). ndeed, the changes in ^{3}H-DA release from nerve terminals in ne CN induced by the local application of α-MT or (+)-mphetamine did not affect ^{3}H-DA release in the contralateral N (Figs 3, 4). We therefore postulate that the asymmetric hanges in DA release observed in the two CN result from the hange in the dendritic release of DA occurring in one SN (Fig. *d* or *e*). This is well illustrated by the experiments shown in Figs and 2. DA released from dendrites in one SN must thus

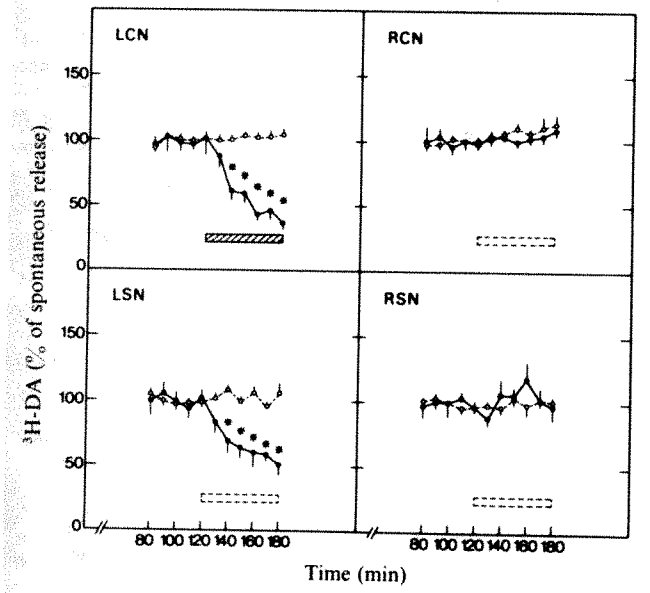

Fig. 3 Effects of α-methyl-*p*-tyrosine application into the left caudate nucleus on the release of ^{3}H-dopamine from the two caudate nuclei and the two substantia nigrae. egulate the activity of a nigral efferent pathway involved in the ontrol of the activity of the contralateral dopaminergic eurones. This could occur as DA acts not only on the opaminergic neurones in the pars compacta but also on other eurones in the pars reticulata[11]. DA could also indirectly affect he activity of the pars reticulata neurones by modifying the elease of transmitters from nigral afferent fibres[12]. As cells of he pars reticulata project to several structures in the brain[13-17], he pathway involved remains to be determined. However, we an still discuss whether the final input of this pathway occurs in ie contralateral SN (Fig. 5*e*) or contralateral CN (Fig. 5*d*). ourth, the effects of unilateral nigral αMT or (+)amphetamine idicate that the asymmetric changes in the dendritic release of)A in both SN are responsible for the opposite asymmetric anges in DA release in both CN. Indeed, the changes in the endritic release observed in the right SN during the application f these drugs in the left SN cannot be related to the opposite anges in ^{3}H-DA release from nerve terminals seen in the ntralateral CN (Fig. 5*d*). If this was the case, parallel changes ould occur in the CN and the SN as observed during the local plication of (+)amphetamine or α-MT in the CN (Figs 3, 4). s there is apparently no direct anatomical connection between

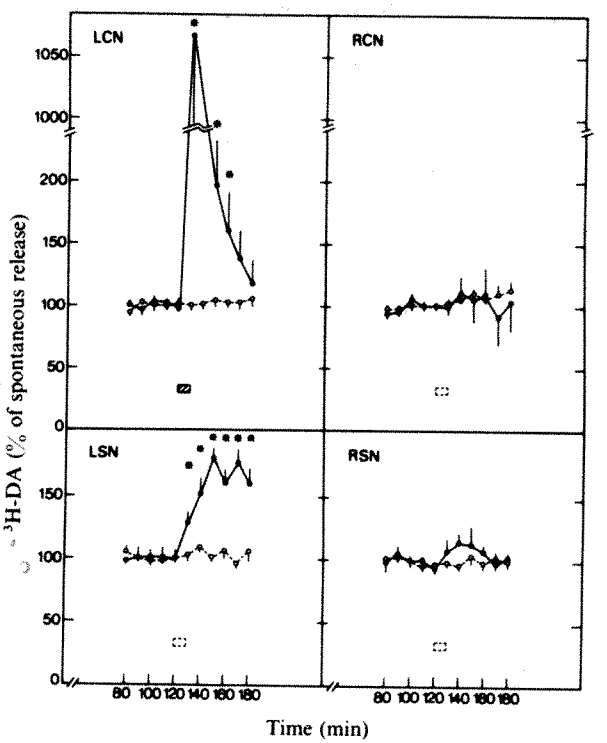

Fig. 4 Effects of (+)amphetamine application into the left caudate nucleus on the release of ^{3}H-dopamine from the two caudate nuclei and the two substantia nigrae. Seven animals were treated as described in Fig. 1 except that (+)amphetamine (10^{-6} M) was applied for 10 min into the left caudate nucleus (LCN). Data are calculated and expressed as in Fig. 1. $*P<0.05$ when compared with corresponding control values obtained in five untreated cats (---○---). ▨, (+)Amphetamine application.

the two SN, a polysynaptic pathway activated or inhibited by DA released from dendrites in one SN must be involved in the reciprocal control of the dendritic release of DA in the contralateral SN and thus in the regulation of the activity of the contralateral dopaminergic neurones (Fig. 5*e*).

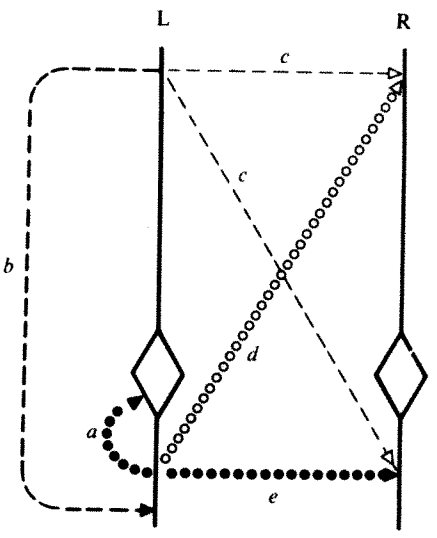

Fig. 5 Influences of dopamine released from dendrites and nerve terminals. Possible direct and indirect influences of dopamine (DA) released from nerve terminals (– – –, – – –) or dendrites (○, ●) of the left (L) dopaminergic neurones on both nigro-striatal dopaminergic pathways (L, R). Our results indicate the existence of the influences *a*, *b* and *e*, and exclude *c* and *d* (see text).

Finally, we should consider why no contralateral effects were observed during the local application of α-MT or (+)amphetamine in the left CN despite the changes in the dendritic release of ^{3}H-DA induced in the ipsilateral SN. Recent experiments suggest that the striato-nigral substance P neurones regulate the activity of the dopaminergic neurones by acting on DA dendritic release[18]. Moreover, in these experiments, there was no effect in the contralateral SN and CN[19], as was the case when dopaminergic drugs were applied in the left CN (Figs. 3, 4). Therefore, the striato-nigral substance P neurones may not only regulate the activity of the ipsilateral nigro-striatal dopaminergic neurones but could also influence the nigral cells involved in the reciprocal regulation of the two dopaminergic systems, and thus counteract the effect of DA on these cells. In fact, substance P nerve terminals are distributed in both the pars compacta and the pars reticulata[20–22] and substance P activates most cells in the SN[23,24]. Furthermore, in contrast to that observed with substance P and its antibody, the unilateral nigral application of agonists or antagonist of γ-aminobutyric acid affected the release of DA in the contralateral CN[25]. These effects were distinct from those induced by dopaminergic drugs, as in all cases the changes in ^{3}H-DA release seen in the two CN were symmetric.

Regarding their role in the coordination of sensory motor processes, it has previously been assumed that the nigro-striatal dopaminergic neurones act merely by modulating the activity of striatal cells. The demonstration of the dendritic release of DA, its important fluctuations in various physiological and pharmacological situations, and its role in regulating the activity, not only of the dopaminergic neurones but also of other nigral efferent pathways, indicate that the nigro-striatal dopaminergic neurones also control the delivery of messages originating from the SN. Such processes, which could be shared by other neurones, will undoubtedly influence our view of the transfer of information in the central nervous system.

The role of mitogenic lectins in T-cell triggering

THE process of T-lymphocyte activation requires the participation of metabolically active non-θ-bearing accessory cells[1]. As first conclusively shown by Habu and Raff[2], this requirement is also true of lectin-dependent triggering. Thus, T-cell activation by mitogenic lectins depends on the presence of Ia-positive non-T cells[3,4]. The mere binding of lectins such as concanavalin A (Con A) to the surface membrane of T cells does not trigger the cells to go through the mitotic cycle. This can only be achieved by the activity of growth factors present in conditioned media (CM) from Con A-stimulated cell cultures[5]. Such growth factors, however, cannot activate normal, resting T cells, although they are competent to maintain activated T cells in exponential growth for indefinite periods of time[6]. Hence, to be mitogenic a lectin must not only induce the *in situ* production of T-cell growth factors, but must also render resting T cells sensitive to the mitogenic activity of these growth factors. In this report we demonstrate that the binding of Con A to purified T cells can in a relatively short time, modify their functional sensitivity to growth factors, even though this binding is not sufficient to stimulate them to proliferate.

In our initial experiments we have used CM obtained at 24 h from Con A-stimulated spleen cell cultures. CM were always tested for T-cell growth factor activity on cultures of purified T-cell blasts[4]. Normal spleen cells, when cultured in such CM where the lectin has been inactivated (in our experiments by supplementation with the specific inhibitor sugar α-methyl-D-mannoside (α-MM)) are not induced to grow[6] (Figs 1, 2 and Table 1). To demonstrate that direct interaction with mitogenic lectins renders T cells sensitive to growth factors, we incubated normal spleen cells in medium, either alone or with 5 μg ml^{-1} Con A, for various periods of time. The cells were then washed

Table 1 Direct interaction of Con A with T cells induces responsiveness to growth factors by expression of acceptor sites

In expts 1 and 2 normal C3H/HeJ spleen cells either untreated or incubated for 30 min in the cold with monoclonal anti-I-A (clone H-116/32, see ref. 14) antibodies were passed over anti-Ig columns (13) and then stimulated in culture (2×10^5 ml^{-1}) with Con A (5 μg ml^{-1}) or a standard preparation of CM at a 50% (v/v) final concentration. ^{3}H-Thymidine uptake was measured on day 3 of culture. This type of experiment has been reproduced on six independent occasions. In expts 3 and 4 T-cell blasts kept in standard CM for over 2 weeks were cultured (5×10^4 ml^{-1}) in the presence of either Con A (5 μg ml^{-1}) or CM (50%, v/v, final concentration) which had been absorbed for 30 min in the cold with the indicated cells (2×10^8 ml^{-1} CM). Cells which had been exposed to Con A for 4 h were washed five times with 20 mg ml^{-1} α-MM before use in the absorption. T-cell blast responses were measured on day 2 after initiation of culture. Mixing experiments showing that the loss of activity in absorbed CM is not due to inhibitory activities have been carried out and partially presented elsewhere [6]. All results are shown as the mean values and s.d. from triplicate cultures. ND, not determined.

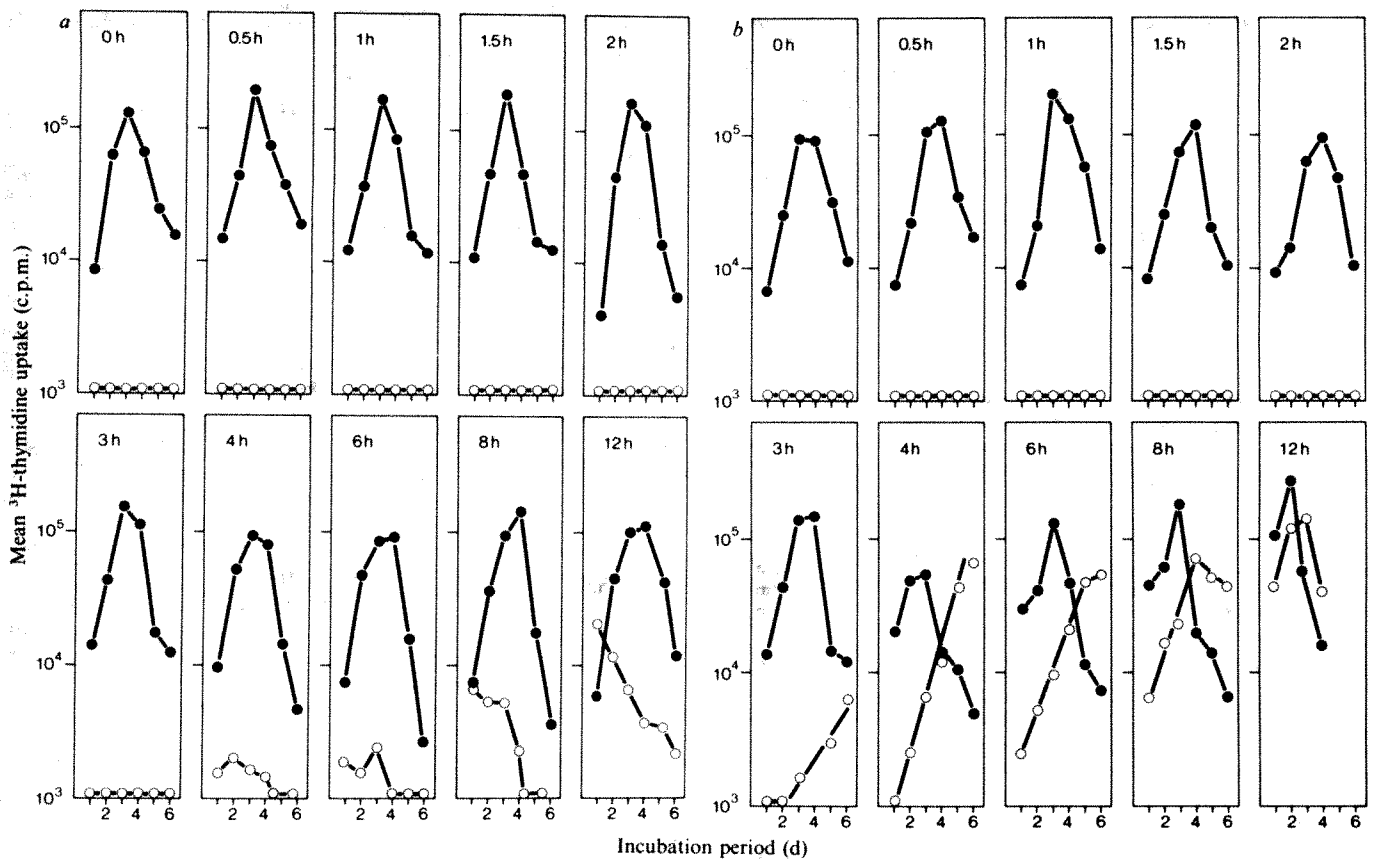

Fig. 1 Induction of responsiveness to growth factors by a short pulse of Con A. C3H/HeJ spleen cells (5×10^6 ml^{-1}) were incubated for the indicated periods of time, at 37 °C, in culture medium [RPMI-1640 containing 50 μg ml^{-1} neomycin, 10 mM HEPES, 5×10^{-5} M 2-mercaptoethanol and 10% fetal calf serum (GIBCO, batch L3644015)] in the presence or absence of 5 μg ml^{-1} Con A (Pharmacia). The cells were then washed five times in medium containing 20 mg ml^{-1} α-MM and recultured (2×10^5 ml^{-1}) either in medium or in growth-factor-containing medium (a 50% (v/v) concentration of CM obtained from 24-h cultures of Con A-stimulated spleen cells, supplemented with 20 mg ml^{-1} α-MM) or in medium containing 5 μg ml^{-1} Con A. The proliferative reponses in triplicate cultures were assayed every day as indicated after a 2-h pulse of ^{3}H-thymidine (Amersham TRK310; specific activity 2 Ci mmol^{-1}; 5 μCi ml^{-1}). *a*, Preincubation in Con A, cultures in Con A (●) or medium (○). *b*, Preincubation in Con A, cultures in CM (○); all cultures with cells preincubated in medium and set up in either medium or CM had values below 1,000 c.p.m. and are not shown. These cells were, however, functionally competent, as demonstrated by their responsiveness to Con A (●) in *b*. The results represent the mean values observed in triplicate cultures; the bars indicating s.d. are smaller than the symbols in the figure. Identical results were observed in three independent experiments.

free of lectin and their reactivity to growth factors was assessed in secondary cultures.

As shown in Fig. 1, incubation of spleen cells with optimal mitogenic doses of Con A for less than 8 h does not result in initiation of growth; this is a good indication that the removal of lectin after preincubation was effective. Exposure to Con A for 8 or 12 h results in a limited degree of cell activation to DNA synthesis, which, however, steadily decreases from day 1. In contrast, Con A pulses as short as 3 h result in the acquisition of responsiveness to growth factors, as demonstrated by the exponential growth observed in such cultures from days 1 to 6. Note that the response to Con A in the secondary cultures is the same whether the cells had been preincubated in the presence or absence of Con A. These experiments demonstrate that normal splenic T cells, which do not respond to either CM or a short pulse of Con A, initiate exponential growth when cultured in CM after the Con A pulse.

As pointed out above, T-cell proliferation depends on growth factors which are induced by mitogenic lectins[4]. We have analysed in detail the kinetics of growth factor production to separate the two triggering events: induction of sensitivity to growth factors (shown in Fig. 1), and production of these growth factors. Normal spleen cells were cultured with 5 μg ml^{-1} Con A, and the culture supernatants collected after various incubation periods and tested for their content in T-cell blast specific growth-factor activity, as described elsewhere[4]. As shown in Fig. 3, before 6 h no growth-promoting activity was detected in the supernatants, and this activity became maximal only between 12 and 24 h.

The difference in the kinetics of these two fundamental steps in T-cell triggering should be remembered when interpreting published observations on the 'commitment' of T lymphocytes to mitosis after mitogen pulses[7–12]. It is clear that in any experimental conditions the limiting factor is the available concentration of growth factors; therefore, such experiments provide information on the conditions for the generation of these molecules.
